

The background of the cover is a collage of three images related to the Fukushima nuclear disaster. The top image shows the Fukushima Daiichi nuclear power plant with a large plume of white steam or smoke rising from one of the reactors against a clear blue sky. The bottom-left image shows a massive, dark, billowing cloud of smoke or steam rising from the ground, partially obscuring some greenery. The bottom-right image shows the skeletal remains of a building, likely a part of the Fukushima Daiichi plant, with smoke rising from the ruins.

Introduction

Ce recueil de documents concernant la catastrophe qui a frappé Fukushima en mars 2011 ne fait pas, à proprement parler, partie des archives du blog *Fukushima-is-still-news* publiées séparément aux Editions de Fukushima (Collection Fukushima-is-still-news, volumes 1 à 16). Le site Internet n'avait en effet été lancé qu'en février 2012. Toutefois, dès les premiers jours, j'avais collecté une certaine quantité d'articles tirés en grande partie de la presse anglophone japonaise. Les articles sont présentés dans cette nouvelle publication « en l'état », sans mise en forme, mais constituent une archive importante des événements de la première année qui a suivi l'accident de la centrale de Fukushima Daiichi. Certains articles se limitent à des liens que j'ai quand même laissés dans le texte, car il doit toujours être possible de demander un accès aux archives des journaux. En annexe, je propose aussi quelques documents et dossiers de l'époque provenant de différentes sources, institutionnelles ou non, qui montrent bien la gravité des événements et le ressenti des auteurs.

MARS 2011

First estimates of total radioactive cesium and iodine emissions from Fukushima plant - March 22, 2011

http://blogs.nature.com/news/thegreatbeyond/2011/03/first_estimates_of_radioactive.html

The amount of the long-lived radioactive isotope cesium-137, and the shorter-lived iodine-131, which have already escaped from the troubled Fukushima power plant in Japan may be significant, **approaching emissions of these isotopes from the Chernobyl accident in 1986**. The [estimates](#) come from Austria's weather service, the **Central Institute for Meteorology and Geodynamics in Vienna**.

Fukushima is no Chernobyl, however, cautions Gerhard Wotawa, a researcher at the centre involved in the study. Crucially, he points out, only a few highly volatile elements, such as iodine, cesium and xenon, have escaped from the Fukushima plant, whereas at Chernobyl the greater damage to the core caused substantial quantities of many other less-volatile isotopes to be released, leading to far higher total radiation levels. It was also "good luck" that prevailing wind patterns pushed much of the radioactive cesium out over the Pacific Ocean away from land, he notes. Even on the days when wind blew material inland, rain close to the plant quickly washed out radioactive material. Little of the plume reached Tokyo, he says, noting also that reported radioactive dose levels in the affected area beyond the immediate area of the plant are low, and falling.

The model's results were calculated by inputting measurements of radioisotope levels at different distances from the plant and then modelling weather patterns and other factors to estimate the amounts released at the source. This model run used measurements of radioisotopes in detector stations in Takasaki in Japan and in Sacramento, California, part of a sophisticated global network of stations created to monitor for nuclear weapons tests – the Comprehensive Nuclear-Test-Ban Treaty Organization (see my long article [last week](#) about the CTBTO network's role in responding to the accident).

The researchers estimate that 3×10^{15} becquerels of Cs-137 (which has a half-life of 30 years) were released during the first two days following the disaster on 11 March. A further 3×10^{16} was released over the next two days, totalling 50% of the Cs-137 emitted in the Chernobyl accident. 4×10^{17} becquerels of I-131, with a half-life of 8 days, were likely released over the same period, roughly 20% of I-131 released from Chernobyl. Wotawa says he was "surprised at the cesium levels, but less so with respect to iodine, as its highly volatile."

Jim Smith, an environmental physicist at the University of Portsmouth, UK, who was not involved in the study, says that the figures are high, and should they prove to be correct "could be of very significant concern". He adds that the modelling was only for the 137 isotope of cesium, but that he'd expect similar amounts of cesium-134 (which has a half-life of two years) to have been released.

Smith agrees with Wotawa that the fact that the prevailing winds on the first two days blowing the plume away from land was "a best case scenario". It could cause significant marine contamination, but the ocean's enormous diluting capacity would reduce any doses, he says, adding that nonetheless fishing bans might be needed near to the Fukushima plant.

Smith says a major caveat to the estimates is that such modelling is "pretty difficult". He says that he hasn't seen enough details to assess how accurate the work is, but that he himself has been surprised by

the high levels of iodine that have been detected in spinach sampled at significant distances from the site. "This suggests that there was a fairly major release of iodine," he says. "This is exactly the sort of modelling we should be doing," he adds. "I'm a bit surprised that we haven't seen similar modelling results from the Japanese; they ought to have an accident response model in place."

To confirm whether the Austrian centre's estimates are accurate Smith says he would like to see the Japanese authorities publishing more radiation measurements, and in particular maps of cesium deposition in the region. "I would have expected that by now they would flying gamma ray spectrometry over the area," he says, adding that a problem is that there is not sufficient data coming out of Japan, in particular on the immediate 20-30 km zone around the plant.

URGENT: Radiation 1,600 times normal level 20 km from Fukushima plant: IAEA

VIENNA, March 22, Kyodo

Radiation 1,600 times higher than normal levels has been detected in an area about 20 kilometers from the crippled Fukushima Daiichi nuclear power plant, International Atomic Energy Agency officials said Monday.

Data collected by an IAEA team show that radiation levels of 161 microsievert per hour have been detected in the town of Namie, Fukushima Prefecture, the officials said.

The government has set an exclusion zone covering areas within a 20-km radius of the plant and has urged people within 20 to 30 km to stay indoors.

<http://english.kyodonews.jp/news/2011/03/80849.html>

....Given that the two had their feet in highly contaminated water, agency spokesman Hidehiko Nishiyama said that the incident has shown that workers should pay special attention to water in proceeding with their work, but added, "We would like to find a delicate balance of keeping delay to the minimum and ensuring the safety of the people working there."

With the three, a total of 17 workers have been exposed to radiation exceeding 100 millisieverts in the country's worst nuclear crisis. The 100 millisieverts is the limit workers are usually allowed to be exposed to in an emergency mission. The limit, however, has been raised to 250 millisieverts for the ongoing crisis....

..The government said, meanwhile, it detected 2.54 million becquerels of iodine and 2.65 million becquerels of cesium, another radioactive substance, from weed leaves in the village of Iitate in Fukushima Prefecture about 40 km northwest from the nuclear plant, far above the provisional limits for food of 2,000 becquerels for iodine and 500 becquerels for cesium.

Abnormally high levels of these materials were also detected again in the sea near the plant, TEPCO said, warning the radiation levels in seawater may keep rising....

.. Despite warnings by an expert, however, government officials and utility company executives appear to have little sense of crisis when it comes to tsunami....

OPINION: Can there be a silver lining to Japan's nuclear crisis?

By Philip White
TOKYO, March 28, Kyodo

The most remarkable thing about the response so far to the "gempatsu shinsai" (nuclear-earthquake disaster) that has engulfed Japan is that there are still people who think nuclear power has a future. Should this be attributed more to the dependence of modern industrialized societies on massive inputs of energy, or to a collective lack of imagination?

We do not yet know how this unfolding catastrophe will end, but we can be sure that if most of the radioactivity in the Fukushima Daiichi Nuclear Power Plant remains on site, then the true believers will claim that this is as bad as it gets and that the risk is worth taking. The environmental damage of localized contamination and releases to sea will be discounted and long-term health impacts from exposure to low levels of radiation will be denied. Even those workers who suffer from acute radiation sickness will not find their way into the most commonly quoted statistics, unless they die promptly.

The truth is that even in the best-case scenario the environmental and human consequences of this disaster will be enormous. The potential impact of a worst-case scenario is beyond most people's comprehension. To give an indication of the amount of radioactive material involved, the total capacity of the three reactors that were operating at the time of the earthquake was double that of the Chernobyl number 4 reactor that exploded 25 years ago in the Ukraine. To this you have to add the radioactivity in the spent fuel pools of all 6 units and of the shared spent fuel pool.

All of this is at risk and, due to the long-term heat-generating properties of the fuel, the situation will not be stabilized any time soon. Even if the radioactivity does not travel far, the release of just a fraction would have incalculable consequences for human beings and the environment.

Besides the true believers, there are also those who regard nuclear energy as a necessary evil. They don't particularly like it, but they see no alternative. But is it true that there is no alternative? For those who can't see beyond the current centralized, supply-driven electrical power systems and who assume an eternally increasing demand for energy, then perhaps it is difficult to imagine how modern societies could survive without nuclear power. But if you allow the possibility of decentralized systems that reward the efficient provision of energy services, rather than the supply of raw energy, then hitherto unimagined options open up.

After last year's oil spill in the Gulf of Mexico and now the Fukushima Daiichi "gempatsu shinsai," people must realize that business as usual is not an option.

To claim that nuclear energy has a future represents a colossal failure of our collective imagination -- a failure to imagine the risks involved and a failure to imagine how we could do things differently. If future generations are to say that there was a silver lining to the cloud of the Fukushima Daiichi disaster, it will be because human beings now looked beyond their recent history and chose to build a society that was not subject to catastrophic risks of human making.

(Philip White is the International Liaison Officer of the Tokyo-based Citizens' Nuclear Information Center.)

<http://english.kyodonews.jp/news/2011/03/81540.html>

..Back on March 21, at TEPCO's head office in Tokyo's Chiyoda Ward, a public relations officer started a news conference by saying, "We have a supplementary remark to make."

"Yesterday, we said the dry vent of the No. 2 reactor was done March 16 to 17 but it was 15," the officer said, correcting the previous day's announcement, as if nothing has happened, trying to move onto a different topic.

A dry vent is an emergency step to release unfiltered steam containing radioactive materials from the containment vessel to the outside. It is an event that has a huge impact on the environment outside a nuclear power plant. But the officer appeared to brazen it out...

But on Saturday, it was disclosed that the company had not informed workers who suffered high levels of radiation at the No. 3 reactor unit about radiation levels of the place where they would be working. The government was also found to have not been informed.

safety subcontracting ?

Given the severe damage done to nuclear fuel facilities, reactors Nos. 1 to 4 are likely to be decommissioned. The man, who has for years worked at Fukushima Daiichi, said he is planning to return to the plant. "I would think it may probably take around 50 years until work to decommission them will end. I hope to continue working till the end," he said.

<http://english.kyodonews.jp/news/2011/03/81984.html>

iodine x 3.355 in seawater

...To cope with a possible situation under which the amount of pumped up contaminated water exceeds the capacity of tanks to accommodate it, a member of the Nuclear Safety Commission of Japan, a government panel, on Tuesday mentioned the need to dig a pool outside the turbine buildings.

Edano said transferring the highly radioactive water to a tanker at sea is an option being studied by the government and nuclear experts.

The top government spokesman also said the experts have been examining the possibility of covering the reactors' buildings damaged by hydrogen explosions with special sheets to reduce the amount of radioactive particles being dispersed from the facility.

Nishiyama also said TEPCO will begin Thursday spraying water containing coating agents at the site to prevent radioactive dust from being carried away by wind and rain."....

Fukushima : « le plutonium cumule tous les risques »

- par Catherine Raizume
- 30/03/2011

<http://www.enviro2b.com/2011/03/30/fukushima-%C2%AB-le-plutonium-cumule-tous-les-risques-%C2%BB/>

Roland Desbordes, *physicien et président de la Commission de recherche et d'information indépendantes sur la radioactivité, laboratoire indépendant créé après la catastrophe de Tchernobyl. La Criirad est particulièrement active depuis la catastrophe de Fukushima, en réalisant ses propres mesures et interpellant les autorités de sûreté nucléaire françaises.*

Les autorités japonaises viennent de révéler avoir découvert du plutonium dans le sol de la centrale de Fukushima. Qu'est-ce que cela implique ?

Le fait que l'on trouve du plutonium dans le pourtour de la centrale n'est pas un scoop, c'est le contraire qui l'aurait été, dans la mesure où du plutonium se trouve dans les cœurs des réacteurs et que ces cœurs de réacteurs sont en fusion. Par ailleurs, ce plutonium étant plus ou moins volatile, aux vues des explosions des montées en températures et de l'ouverture des fissures des cuves, cela paraissait complètement irréaliste que l'on n'en trouve pas.

Cela dit, ce plutonium complique encore un peu plus le travail des salariés de Tecpo sur place. A becquerel égal, le plutonium est 100 000 plus toxique que l'iode ou le césium.

A vos yeux, s'agit-il déjà d'une catastrophe environnementale ?

On y est déjà de plein pied, d'autant plus que le plutonium 239 est un métal lourd radiotoxique à vie longue, de l'ordre de 4 000 ans. Il a un cheminement dans la chaîne alimentaire catastrophique. Le plutonium cumule tous les risques.

Cette pollution au plutonium sera-t-elle limitée au réacteur n°3 ici en cause ?

Non, si le réacteur n°3 en contenait dès l'origine dans une proportion comprise vraisemblablement entre 6 à 8%, les réactions de fusion ont également fabriqué du plutonium sur les autres réacteurs touchés.

Quelle est la radioactivité relevée autour de la centrale de Fukushima ?

On n'a aucune information à ce sujet. On sait juste que les 20 km autour de la centrale sont une zone évacuée. Mais à mon avis, la contamination doit être importante. On sait que dans la province d'Ibaraki, une région située à plus d'une centaine de kilomètres de la centrale, on constate déjà une contamination radioactive avérée des produits alimentaires, qui dépasse les limites de commercialisation.

Et quelle est la situation à Tokyo ?

Située à environ 250 km de la centrale de Fukushima, Tokyo a enregistré le passage de deux petits panaches radioactifs, un premier vers le 15 mars, et l'autre autour du 22 mars. Si ces panaches n'étaient pas très intenses, ils ont cependant suffi à polluer immédiatement l'eau du robinet, ce qui est très inquiétant, à des valeurs jusqu'à 20 becquerels par litre. Ces relevés ont d'ailleurs contraints les autorités japonaises à recommander de ne pas utiliser cette eau polluée pour les biberons.

Pourquoi ces panaches radioactifs japonais ont-ils contaminé aussi rapidement l'eau du robinet ?

A partir du moment où l'on relève des particules radioactives dans l'air, elles se retrouvent obligatoirement au sol. Ce qui est surprenant ici, c'est la rapidité avec laquelle cette contamination de l'air s'est répandue dans l'eau du robinet.

En France, pourquoi votre laboratoire a-t-il remis en cause la transparence des autorités de sûreté nucléaire comme l'IRSN ?

Ce que la Criirad critique, c'est la présentation des résultats de l'IRSN, notamment ceux relevés samedi matin, sur la balise dans le Puy-de-Dôme. On s'est aperçu qu'ils avaient effectué leurs relevés à partir

de filtres papier, qui ne retiennent environ que 1/5e de l'iode radioactif présent dans l'air, manquant l'iode sous forme gazeuse.

Cela veut-il dire que les mesures d'iode présentées par l'IRSN doivent être multipliées par 5 ?

Absolument, c'est d'ailleurs ce qu'a fait l'IRSN lui-même le soir même.

Malgré cette correction, ces relevés de la radioactivité détectée demeurent très faibles ?

On reste dans des taux très faibles, nous ne remettons pas ça en doute. Ce qui nous a semblé choquant, c'est la présentation de ces résultats, surtout pour un laboratoire d'Etat très compétent, ce n'est pas bien.

Pourquoi la Criirad est-elle également récemment montée au créneau pour obtenir les mesures de radioactivité relevées par le réseau international CTBTO ?

Parce qu'on ne les a pas. On invoque tous un tas de bonnes raisons pour ne pas les donner. Ces données sont transmises aux Etats, mais les Etats invoquent le secret défense comme en France, ce qui est totalement faux.

Quelle est la vraie raison de ce manque de transparence selon vous ?

On refuse de divulguer des informations obtenues grâce à des fonds publics, que nous contribuons à financer, en tant que citoyens. C'est scandaleux.

De quoi des Etats comme la France ont-ils peur ?

Je n'en sais rien, il faut le leur demander. En France, c'est le CEA qui est destinataire de ces mesures.

news : smoke temporarily seen at Fukushima Daiichi turbine building (19. hr jap. time on March 30)

http://www.lemonde.fr/japon/article/2011/03/29/fukushima-la-menace-nucleaire-perdurera-sur-le-long-terme_1500362_1492975.html

De l'iode 131 détecté en Drôme-Ardèche

Posté le 30/03/2011 à 15:28 | lu 137 fois |  0 réaction |

Le laboratoire de la CRIIRAD a analysé, dans la nuit du 29 mars, un échantillon d'eau de pluie collecté du dimanche 27 mars à 10h30 au lundi 28 mars à 8h, sur la zone de Valence et représentatif de la Drôme-Ardèche. Le CRIIRAD a détecté dans l'eau un élément radioactif : l'iode 131, présent toutefois à un faible niveau. Le niveau de radioactivité a été mesuré à 0,7 becquerel (Bq) par litre. Il pourrait atteindre plusieurs centaines de Bq par mètre carré, cumulés sur les quinze prochains jours. En comparaison, le laboratoire note qu'en 1986, suite à la catastrophe de Tchernobyl, les retombées d'iode 131 sur la France, ont varié entre les régions de 1000 Bq/m² à 200.000 Bq/m². La contamination actuelle est plus faible mais néanmoins mesurable. La CRIIRAD indique que l'iode détectée ne présente, pour le moment, aucun risque pour la santé.

COMMUNIQUE CRIIRAD

http://www.criirad.org/actualites/dossier2011/japon/30-03_alerte_sanitaire_japon.pdf

30 mars 2011 - 18h

Depuis lundi 28 mars, l'attention est focalisée sur l'activité de l'eau de mer et certains médias s'inquiètent de la survenue d'une « catastrophe écologique » 1. La CRIIRAD rappelle que l'urgence concerne la protection sanitaire des habitants des zones contaminées. Depuis le 12 mars dernier, ils subissent, jour après jour, heure après heure, l'impact des rejets radioactifs de la centrale nucléaire de FUKUSHIMA DAIICHI. Toutes les voies d'exposition se cumulent :

- **Exposition aux rayonnements qu'émettent les aérosols et les gaz radioactifs que les vents transportent** vers les zones habitées, celles de la Préfecture de Fukushima, bien sûr, mais aussi bien au-delà de la ville de Sendai, à 100 km au nord et bien au-delà de Tokyo à 230 km au sud.
- **Exposition aux rayonnements émis par les produits radioactifs qui retombent progressivement au sol** (du fait de la gravitation, des pluies et de la neige) et s'accumulent sur les surfaces.

Les débits de dose sont multipliés par 10 à bien plus de 100 km de la centrale nucléaire, par 100 à quelques 60 ou 70 km de distance et quand l'on considère un périmètre d'une cinquantaine de kilomètres certaines valeurs dépassent de 1 000 fois le niveau normal. Il s'agit là de zones où les populations n'ont été ni évacuées, ni confinées. Et ces niveaux d'exposition ne correspondent pas à des élévations ponctuelles des flux de rayonnements. Rappelons qu'une valeur de 8 $\mu\text{Sv/h}$ (qui ne constitue pas un maximum) correspond à 64 μSv pour 8 h de présence et à 1 152 μSv sur 18 jours, soit une valeur supérieure à la limite de dose maximale

admissible sur 1 an (1 mSv). Et si les gaz radioactifs ont pénétré, comme nous le pensons, à l'intérieur des habitations, il faut calculer les doses d'exposition externe sur la base de 24 h/jour (on arrive alors à plus de 3 mSv/an, soit 3 fois la limite de dose maximale admissible sur 1 an).

○ **Contamination externe à cause du dépôt des particules radioactives sur la peau et les cheveux** (une contamination qui peut très facilement se transformer en contamination interne si la peau comporte des blessures ou de simples microlésions ; si les doigts sont portés à la bouche, au

nez ; si la personne manipule des aliments sans s'être lavé les mains ; si les aérosols déposés sur les cheveux sont remis en suspension et inhalés...) ;

○ **Contamination interne par INHALATION** des aérosols et gaz radioactifs présents dans l'air : parce que l'on ne peut pas s'arrêter de respirer, parce que les simples masques à poussières portés par la population ne procurent AUCUNE PROTECTION contre les iodes radioactifs gazeux dont l'air est chargé ; parce que le confinement à l'intérieur des bâtiments est une contre mesure de COURT TERME qui n'aurait jamais dû être

prolongée sur plus de 15 jours : soit les personnes s'asphyxient parce que le confinement fonctionne, soit il est imparfait, et elles sont alors approvisionnées en oxygène ET en produits radioactifs ! ;

○ **Contamination interne par INGESTION d'eau et d'aliments contaminés** : parce que le contrôle des aliments à risque a commencé de façon tardive ; parce que ne sont retirés de la consommation que les aliments dont le taux de radioactivité dépasse les normes, qui sont plus protectrices que les normes en vigueur en France et en Europe, mais qui restent quand très élevées².

Pour calculer la dose de rayonnement reçue par une personne, et évaluer ainsi le risque sanitaire auquel elle est exposée, **il faut tenir compte de toutes les voies d'exposition, interne et externe, de tous les radionucléides, de tous les aliments**. Ce travail est difficile à réaliser étant donné l'absence de mesure sur les débits de dose dans les zones les plus exposées pendant tout le début de la crise, la rareté des contrôles relatifs à la contamination de l'air, les interrogations sur la composition isotopique des rejets radioactifs, l'absence de résultats sur les niveaux d'exposition à l'intérieur des habitations où la population est confinée (rayon de 30 km).

... Compte tenu de l'importance de la contamination, compte tenu de l'impossibilité de prévoir quelles quantités de produits radioactifs seront encore rejetés demain, après-demain... dans l'atmosphère, la CRIIRAD réitère son appel aux autorités japonaises pour que le maximum soit fait pour évacuer la population bien au-delà du rayon de 20 km et pour apporter aux populations les plus affectées le maximum de produits alimentaires non contaminés. Elle appelle également la communauté internationale à apporter tout l'aide logistique et financière possible pour que les interventions se fassent au plus vite. Tant de jours ont déjà été perdus

<http://english.kyodonews.jp/news/2011/04/82524.html>

TEPCo se serait encore trompé dans ses chiffres (on groundwater radioactivity)

...In an effort to prevent radioactive dust from being dispersed by wind and rain from the plant, TEPCO will begin a test spraying of a water-soluble resin, which has coating effects, later in the day.

As a result of hydrogen explosions, masses of debris have been strewn around the site, which was ravaged by the March 11 earthquake and tsunami. A total of 60,000 liters of resin will be sprayed over a period of two weeks.

The engineers will also start moving fresh water carried by a U.S. Navy barge to tanks at the plant, which will be injected into the reactors to cool them down.

The barge containing 300,000 gallons of fresh water is now moored at the Daiichi power station, while another ship carrying an additional 200,000 gallons is expected to arrive later Friday, according to the U.S. Navy.

Not enough dosimeters for all the workers

<http://english.kyodonews.jp/news/2011/04/82534.html>

“...Some workers were sharing dosimeters while doing the same job because many of the devices were destroyed in the March 11 quake and tsunami, a situation that was not "desirable from the viewpoint of ensuring workers' safety," said Hidehiko Nishiyama, a spokesman for the agency.

But the plant operator, known as TEPCO, had been able to secure a total of 420 dosimeters **by Thursday**, sufficient for each of the workers to wear a device when working at the radiation-leaking site.

TEPCO officials said the number of dosimeters available had declined from an initial 5,000 to 320 after the tsunami damaged devices. It had been managing the workers' radiation exposure by ordering the leader of each work team to wear a dosimeter, but some workers had expressed concern about the situation.

Following the warning issued to the company on Thursday, Nishiyama said, "From today, all of the workers will wear dosimeters. And if each individual cannot get one, the work should not take place."

Is this a joke (1st of April)? These workers have - for some of them at least - been working for x days ! How have the doses they get every time been calculated so far?

Work on crippled reactors

URGENT: Gov't eyes injecting nitrogen into reactor vessels to prevent blasts

TOKYO, April 1, Kyodo

The government and Tokyo Electric Power Co. are considering injecting nitrogen into containment vessels of the Fukushima Daiichi nuclear power plant's reactors to prevent hydrogen explosions, government sources said Friday.

<http://english.kyodonews.jp/news/2011/04/82753.html>

tainted water confirmed to have swept into sea from nuke plant

The New York Times

April 2, 2011

From Far Labs, a Vivid Picture of Japan Crisis

By [WILLIAM J. BROAD](#)

For the clearest picture of what is happening at [Japan](#)'s Fukushima Daiichi nuclear power plant, talk to scientists thousands of miles away.

Thanks to the unfamiliar but sophisticated art of atomic [forensics](#), experts around the world have been able to document the situation vividly. Over decades, they have become very good at illuminating the hidden workings of nuclear power plants from afar, turning scraps of information into detailed analyses.

For example, an analysis by a French energy company revealed far more about the condition of the plant's reactors than the Japanese have ever described: water levels at the reactor cores dropping by as much as three-quarters, and temperatures in those cores soaring to nearly 5,000 degrees Fahrenheit, hot enough to burn and melt the zirconium casings that protect the fuel rods.

Scientists in Europe and America also know from observing the explosions of hydrogen gas at the plant that the nuclear fuel rods had heated to very dangerous levels, and from radioactive plumes how far the rods had disintegrated.

At the same time, the evaluations also show that the reactors at Fukushima Daiichi escaped the deadliest outcomes — a complete meltdown of the plant.

Most of these computer-based forensics systems were developed after the 1979 partial meltdown at Three Mile Island, when regulators found they were essentially blind to what was happening in the reactor. Since then, to satisfy regulators, companies that run nuclear power plants use snippets of information coming out of a plant to develop simulations of what is happening inside and to perform a variety of risk evaluations.

Indeed, the detailed assessments of the Japanese reactors that Energy Secretary [Steven Chu](#) gave on Friday — when he told reporters that about 70 percent of the core of one reactor had been damaged, and that another reactor had undergone a 33 percent meltdown — came from forensic modeling.

The bits of information that drive these analyses range from the simple to the complex. They can include everything from the length of time a reactor core lacked cooling water to the subtleties of the gases and radioactive particles being emitted from the plant. Engineers feed the data points into computer simulations that churn out detailed portraits of the imperceptible, including many specifics on the melting of the hot fuel cores.

Governments and companies now possess dozens of these independently developed computer programs, known in industry jargon as “safety codes.” Many of these institutions — including ones in Japan — are relying on forensic modeling to analyze the disaster at Fukushima Daiichi to plan for a range of activities, from evacuations to forecasting the likely outcome.

“The codes got better and better” after the accident at Three Mile Island revealed the poor state of reactor assessment, said Michael W. Golay, a professor of nuclear science and engineering at the [Massachusetts Institute of Technology](#).

These portraits of the Japanese disaster tend to be proprietary and confidential, and in some cases secret. One reason the assessments are enormously sensitive for industry and government is the relative lack of precedent: The atomic age has seen the construction of nearly 600 civilian power plants, but according to the World Nuclear Association, only three have undergone serious accidents in which their fuel cores melted down.

Now, as a result of the crisis in Japan, the atomic simulations suggest that the number of serious accidents has suddenly doubled, with three of the reactors at the Fukushima Daiichi complex in some stage of meltdown. Even so, the public authorities have sought to avoid grim technical details that might trigger alarm or even panic.

“They don’t want to go there,” said Robert Alvarez, a nuclear expert who, from 1993 to 1999, was a policy adviser to the secretary of energy. “The spin is all about reassurance.”

If events in Japan unfold as they did at Three Mile Island in Pennsylvania, the forensic modeling could go on for some time. It took more than three years before engineers lowered a camera to visually inspect the damaged core of the Pennsylvania reactor, and another year to map the extent of the destruction. The core turned out to be about half melted.

By definition, a meltdown is the severe overheating of the core of a nuclear reactor that results in either the partial or full liquefaction of its uranium fuel and supporting metal lattice, at times with the atmospheric release of deadly radiation. Partial meltdowns usually strike a core’s middle regions instead of the edge, where temperatures are typically lower.

The main meltdowns of the past at civilian plants were Three Mile Island in 1979, the St.-Laurent reactor in France in 1980, and Chernobyl in Ukraine in 1986.

One of the first safety codes to emerge after Three Mile Island was the Modular Accident Analysis Program. Running on a modest computer, it simulates reactor crises based on such information as the duration of a power blackout and the presence of invisible wisps of radioactive materials.

Robert E. Henry, a developer of the code at Fauske & Associates, an engineering company near Chicago, said that a first sign of major trouble at any reactor was the release of hydrogen — a highly flammable gas that has fueled several large explosions at Fukushima Daiichi. The gas, he said in an interview, indicated that cooling water had fallen low, exposing the hot fuel rods.

The next alarms, Dr. Henry said, centered on various types of radioactivity that signal increasingly high core temperatures and melting.

First, he said, “as the core gets hotter and hotter,” easily evaporated products of atomic fission — like iodine 131 and cesium 137 — fly out. If temperatures rise higher, threatening to melt the core entirely, he added, less volatile products such as strontium 90 and plutonium 239 join the rising plume.

The lofting of the latter particles in large quantities points to “substantial fuel melting,” Dr. Henry said.

He added that he and his colleagues modeled the Japanese accident in its first days and discerned partial — not full — core melting.

Micro-Simulation Technology, a software company in Montville, N.J., used its own computer code to model the Japanese accident. It found core temperatures in the reactors soaring as high as 2,250 degrees Celsius, or more than 4,000 degrees Fahrenheit — hot enough to liquefy many reactor metals.

“Some portion of the core melted,” said Li-chi Cliff Po, the company’s president. He called his methods simpler than most industry simulations, adding that the Japanese disaster was relatively easy to model because the observable facts of the first hours and days were so unrelentingly bleak — “no water in, no injection” to cool the hot cores.

“I don’t think there’s any mystery or foul play,” Dr. Po said of the disaster’s scale. “It’s just so bad.”

The big players in reactor modeling are federal laboratories and large nuclear companies such as General Electric, Westinghouse and Areva, a French group that supplied reactor fuel to the Japanese complex.

The Sandia National Laboratories in Albuquerque wrote one of the most respected codes. It models whole plants and serves as a main tool of the [Nuclear Regulatory Commission](#), the Washington agency that oversees the nation's reactors.

Areva and French agencies use a reactor code-named Cathare, a complicated acronym that also refers to a kind of goat's milk cheese.

On March 21, [Stanford University](#) presented an invitation-only panel discussion on the Japanese crisis that featured Alan Hansen, an executive vice president of Areva NC, a unit of the company focused on the nuclear fuel cycle.

"Clearly," he told the audience, "we're witnessing one of the greatest disasters in modern time."

Dr. Hansen, a nuclear engineer, presented a slide show that he said the company's German unit had prepared. That division, he added, "has been analyzing this accident in great detail."

The presentation gave a blow-by-blow of the accident's early hours and days. It said drops in cooling water exposed up to three-quarters of the reactor cores, and that peak temperatures hit 2,700 degrees Celsius, or more than 4,800 degrees Fahrenheit. That's hot enough to melt steel and zirconium — the main ingredient in the metallic outer shell of a fuel rod, known as the cladding.

"Zirconium in the cladding starts to burn," said the slide presentation. At the peak temperature, it continued, the core experienced "melting of uranium-zirconium eutectics," a reactor alloy.

A slide with a cutaway illustration of a reactor featured a glowing hot mass of melted fuel rods in the middle of the core and noted "release of fission products" during meltdown. The products are radioactive fragments of split atoms that can result in cancer and other serious illnesses.

Stanford, where Dr. Hansen is a visiting scholar, posted the slides online after the March presentation. At that time, each of the roughly 30 slides was marked with the Areva symbol or name, and each also gave the name of their author, Matthias Braun.

The posted document was later changed to remove all references to Areva, and Dr. Braun and Areva did not reply to questions about what simulation code or codes the company may have used to arrive at its analysis of the Fukushima disaster.

"We cannot comment on that," Jarret Adams, a spokesman for Areva, said of the slide presentation. The reason, he added, was "because it was not an officially released document."

A European atomic official monitoring the Fukushima crisis expressed sympathy for Japan's need to rely on forensics to grasp the full dimensions of the unfolding disaster.

"Clearly, there's no access to the core," the official said. "The Japanese are honestly blind."

TEPCO to release radioactive water into Pacific (as of Monday 4th April)

Fukushima crisis poses challenge to IAEA members: Amano

VIENNA, April 4, Kyodo

<http://english.kyodonews.jp/news/2011/04/83064.html>

The current nuclear crisis in Japan has enormous implications for nuclear power and poses a major challenge to all countries concerned, Yukiya Amano, head of the International Atomic Energy Agency, said Monday at the opening of a review meeting on the Convention on Nuclear Safety.

"We cannot take a business-as-usual approach," Amano said. "More needs to be done to strengthen the safety of nuclear power plants so that the risk of a future accident is significantly reduced."

He told representatives of the 72 contracting states to the convention, which took effect in 1996, that **public confidence in nuclear power has to be restored** by the most robust international safety standards and full transparency.

The participants in the review meeting, which takes place every three years, are to discuss reports on nuclear safety submitted by contracting parties, including Japan, seven months ahead of the meeting.

A seminar focusing on the accident at Fukushima Daiichi atomic plant will take place on the sidelines of the meeting later Monday. According to Amano, **specialists from Japan's Nuclear and Industrial Safety Agency, Tokyo Electric Power Co., which operates the plant, the United States and European countries will give presentations.**

Note: wouldn't that be "business as usual"?(between themselves)

<http://english.kyodonews.jp/news/2011/04/83076.html>

Tokyo Electric Power Co. began disposing of a total of 10,000 tons of water containing low-level radioactive substances in the Pacific Ocean on Monday from the crippled Fukushima Daiichi nuclear power plant to make room to store more highly polluted water filling the No. 2 reactor turbine building, as the water is hampering the plant's restoration work, it said.

Separately from the contaminated water kept in a waste processing building, the company also said it plans to release 1,500 tons of groundwater, also containing radioactive materials, near the No. 5 and No. 6 reactors. The government said the water disposal will pose "no major health risk" and is inevitable in order to secure safety.

....

Highly radioactive water has been filling up the basement of the No. 2 reactor turbine building and the tunnel-like trench connected to it. Meanwhile, the water in the pit is believed to have come from the No. 2 reactor core, where fuel rods have partially melted.

TEPCO has revealed that radioactive iodine-131 **more than 10,000 times the legal concentration limit** was detected in the water found in the pit.....

<http://english.kyodonews.jp/news/2011/04/83119.html>

Tokyo Electric Power Co. on Monday took the unprecedented measure of dumping 10,000 tons of low-level radioactive water in the Pacific Ocean from a facility at its crippled Fukushima Daiichi nuclear power complex to make room for the storage of more highly contaminated water, which is hampering restoration work at the plant.

With the total amount of water to reach 11,500 tons, including contaminated groundwater from near the No. 5 and No. 6 reactors, the government said the disposal was unavoidable in order to secure safety. The level of radioactive substances in the water is **up to 500 times the legal limit permitted for release in the environment**.

[note : A few hours earlier, one could read (see above) the following : « The total amount of contaminated water to be released will be 15,000 tons and the concentration of the waste water is estimated at **about 100 times the legal limit**, which is deemed as a relatively low level, Tokyo Electric Power Co. said.”

....

Nishiyama also said that it had become necessary to release 1,500 tons of groundwater, also containing radioactive materials, found near the Nos. 5 and 6 reactor turbine buildings out of concern that the water could drown safety-related equipment.

Of the six reactors at the Fukushima Daiichi plant, the Nos. 5 and 6 reactors have achieved "cold shutdown," but Nishiyama said that he is afraid their cooling functions could be lost if the water level increases inside the buildings.

.... San Francisco rainwater radiation spikes above US drinking water standards

Radiation from Japan rained on Berkeley, California, during recent storms at levels that exceeded drinking water standards by 181 times. A rooftop water monitoring program managed by the University of California at Berkeley's Department of Nuclear Engineering detected substantial spikes in rain-borne iodine-131 during those torrential downpours. The levels exceeded federal drinking water thresholds, known as Maximum Contaminant Levels -- or MCLs -- by as much as 181 times or 18,100%.

More than one in 10 nuclear power plants at risk from earthquakes

<http://www.independent.co.uk/news/science/more-than-one-in-10-nuclear-power-plants-at-risk-from-earthquakes-2260817.html>

Many stations are in countries that would be less able than Japan to cope with disasters

By Jonathan Owen
Sunday, 3 April 2011

Scores of nuclear power plants worldwide are at risk from tsunamis or earthquakes similar to the natural disasters that crippled Japan's Fukushima reactors, according to new research. Many at-risk plants are in countries less able to cope with a disaster than Japan, experts have warned.

Seventy-six operating power stations in Japan, Taiwan, China, South Korea, India, Pakistan and the US are located in areas close to coastlines deemed vulnerable to tsunamis.

Of 442 nuclear power stations globally, more than one in 10 are situated in places deemed to be at high or extreme risk of earthquakes – in Japan, the US, Taiwan, Armenia and Slovenia – according to a new study by the analysts Maplecroft.

Helen Hodge, Maplecroft's natural hazards analyst, said: "Although Japanese nuclear facilities are particularly exposed, other countries could also face similar risks. South Korea, Taiwan, southern China, India, Pakistan and the west coast of the US have operating or planned nuclear facilities on tsunami-exposed coastlines, while nuclear sites in areas of high or extreme risk of earthquakes can be found in western US, Taiwan, Armenia, Iran and Slovenia."

Emeritus Professor Keith Barnham, a physicist from Imperial College London, commented: "Japan is one of the most advanced technological countries but one can see the problems they are having in coping with the aftermath. One fears for the reactors planned or operational in the environmentally unsafe areas of less technologically developed countries."

Nuclear safety experts cite the example of an ageing Russian-built nuclear reactor only 30km from the Armenian capital, Yerevan. In December 1988, a powerful earthquake, which led to the deaths of at least 25,000 people, occurred in north-west Armenia. The following year, the Metsamor nuclear plant was shut down due to safety concerns regarding "seismic vulnerability". Although one of its reactors is now being decommissioned, another remains operational. The International Atomic Energy Association (IAEA) has been involved in safety improvements at the plant for more than a decade.

But, according to the World Nuclear Association, "The present Metsamor plant is a concern to the European Union and to neighbouring Turkey, 16km away. There have been various calls to shut it down ... but Armenia is very dependent on it and has said that it will remain open until a replacement is commissioned."

The risks of future natural disasters have been recognised by the IAEA in recent years, which set up the International Seismic Safety Centre in 2008. Its safety guidelines on earthquakes and tsunamis are being revised following the incident at Japan's Fukushima Daiichi nuclear plant.

The Japanese crisis has reignited the debate over nuclear safety. As a result, several nations, including Italy, Switzerland and Germany, have put new reactor plans on hold. The nuclear plant at Fukushima was crippled after an earthquake and tsunami devastated north-east Japan last month.

James Acton, nuclear expert at the Carnegie Endowment for International Peace, commented: "The key question is whether we have correctly predicted the risk that a reactor could be hit by a disaster (natural or man-made) that is bigger than it is designed to withstand. This issue should be urgently reviewed by all states with reactors."

Jeremy Gordon, editor of World Nuclear News, predicted there would be a "step change" in efforts to improve safety. "While it's true that many, if not most countries, would be less prepared than Japan to face an unprecedented natural disaster and nuclear accident on this scale," he said, "the country involved in future would likely have a far better practical support network from other governments and practical experts in industry."

Dr Gordon Woo, an IAEA consultant, said there was already a "significant degree" of seismic technology transfer by the IAEA to less advanced nations. He predicted this would increase after the Japanese disaster.

Japan Atomic Energy Commission.. (5 members)

Commission chairman Shunsuke Kondo said the current crisis contradicts the conventional argument that nuclear power generation is safe. "We have to admit that there has been an error in the criteria of judgment in promoting the country's nuclear power policy," he said....

After its regular meeting Tuesday, the five-member commission expressed its view on the current nuclear crisis, saying it has shaken confidence in the country's efforts to ensure the safety of nuclear power...

The Japan Atomic Energy Commission was established in 1956 to promote the country's nuclear power development systematically. It ceded its authority on safety regulation to the Nuclear Safety Commission of

Japan in 1978 after Japan's first nuclear-powered ship, the 8,242-ton Mutsu, developed a radiation leak during a test run in 1974.

<http://english.kyodonews.jp/news/2011/04/83228.html> tuesday 5th

A total of 60,000 tons of radioactive water is believed to be flooding the basement of reactor buildings and underground trenches connected to them at the crisis-hit Fukushima nuclear plant, the industry minister said Tuesday, adding its operator will later remove the liquid obstructing recovery work...

The Nuclear and Industrial Safety Agency said the 60,000 tons of water -- 20,000 tons each from the Nos. 1-3 reactor buildings and trenches -- will be stored in tanks at the units, a facility for nuclear waste disposal at the site, an artificial floating island called a "megafloat," U.S. Navy barges and provisional tanks.

The complex for nuclear waste disposal can accommodate 30,000 tons of such water but it will take a while before it can store the liquid because TEPCO will try to ensure that radioactive water will not be leaked from the facility by using coating agents, the agency said.

The provisional tanks will be shipped to the Fukushima plant by the end of this month, it added.

...he water containing radioactive iodine-131 more than 10,000 times the legal concentration limit has been leaking from a cracked seaside pit connected to the No. 2 reactor turbine building.

In a new finding, TEPCO said Tuesday a seawater sample taken Saturday near the No. 2 reactor's water intake showed the iodine-131 concentration at 7.5 million times the maximum allowable level under law....

Note: these are numbers from Saturday, today is Tuesday

Japan defends radioactive water disposal, vows to fully inform world

..

He also said the dumping does not violate the 1986 Convention on Early Notification of a Nuclear Accident, which obligates nations to provide data such as the accident's time, location and radiation releases to affected states when harmful trans-boundary radiation release is feared...

http://www.google.com/hostednews/afp/article/ALeqM5iUtd8qBnjSzzDmhJXslDV_H0CxRw?docId=CNG.bcf74a4d0a9bb29afe4e98cfe57a8c2d.1311

Fukushima reviews to cause 3-month delay in UK nuclear program

Barcelona (Platts)--5Apr2011/708 am EDT/1108 GMT

<http://www.platts.com/RSSFeedDetailedNews/RSSFeed/ElectricPower/8749355>

There will be a minimum three-month delay in new reactor construction in the UK as a result of plans for nuclear safety reviews in the wake of the nuclear accident at Tokyo Electric's Fukushima-1 nuclear power plant in Japan, UK officials said Tuesday.

The UK Health and Safety Executive said it will not publish its final conclusions on the safety of the Areva EPR and Westinghouse AP1000 reactor designs until after a nuclear safety review investigates the implications of the nuclear accident at Fukushima on the safety of UK reactors.

That review, being conducted by Chief Nuclear Inspector Mike Weightman, is **not expected to be complete until September** and the HSE had been planning to publish its conclusions under the generic design assessment, or GDA, program at the end of June. The GDA program is reviewing the safety of the reactor designs for construction in the UK.

In a statement Tuesday, HSE said that it would proceed to publish all the GDA safety issues on the two reactor designs that it had identified as of June 30, as well as the reactor vendors' resolution plans for those issues.

But it said it would not issue its final conclusions in the form of design acceptance confirmations until after the completion of the Weightman report.

Among the GDA issues to be published at the end of June will be a requirement that the reactor vendors address any issues raised by the Weightman report.

GDA issues must be resolved before the agency will issue final design acceptance confirmations for the reactors, HSE said.

Nuclear safety-related construction of new reactors cannot proceed if there are any unresolved GDA issues, HSE has said.

<http://english.kyodonews.jp/news/2011/04/83320.html>

..The mayor said the government and TEPCO were slow to respond to the trouble at the Fukushima plant because they had believed such an accident would not hit it.

The government and TEPCO were overconfident in their technologies and they ended up responding only after problems had occurred, he said, adding, "Nuclear power is a monster. They were caught off guard, saying nuclear power is safe."

Concerning relations between nuclear power plants and host municipalities, Murakami noted that nuclear power plants are a very large presence for host local governments which cannot easily depart from them in the aspects of finance and employment.

The mayor said the central government, utility firms and host municipalities had all been wrong in becoming mutually dependent on nuclear power without thinking about its potential threats....

<http://english.kyodonews.jp/news/2011/04/83365.html>

..

The government's Nuclear and Industrial Safety Agency told a press conference that TEPCO is expected to continue injecting the agent in the hope of completely stopping the leak of highly contaminated water.

But the marine environment appears to be seriously contaminated already. A seawater sample taken Saturday near the No. 2 reactor's water intake showed a radioactive iodine-131 concentration of 7.5 million times the maximum permitted level under law, TEPCO said Tuesday.

Radioactive cesium exceeding the maximum permitted limit was detected in young sand lance in the sea near the northern part of Ibaraki Prefecture, south of Fukushima. It is the first time that contamination levels in seafood have exceeded the limit.

The company said it will have to discharge a total of 11,500 tons of low-level contaminated water from the plant into the sea by this weekend.

<http://english.kyodonews.jp/news/2011/04/83451.html>

Tokyo Electric Power Co. succeeded in stopping highly radioactive water from leaking into the Pacific Ocean from the crippled Fukushima Daiichi nuclear power plant early Wednesday, while saying it is considering injecting nitrogen to prevent a possible hydrogen explosion from occurring at the No. 1 reactor.

The highly toxic water, confirmed to have been flowing from around a seaside pit located near the No. 2 reactor water intake on Saturday, stopped at 5:38 a.m. after the plant operator injected some 6,000 liters of chemical agents, including what is called water glass.

The government's nuclear agency said it ordered the utility known as TEPCO to keep monitoring the pit to check whether the water leakage has completely stopped, and noted there is the possibility that the water, which has lost an outlet, may show up from other areas inside the plant's premises.

...

Meanwhile, TEPCO said it may inject nitrogen into the No. 1 reactor's containment vessel possibly later Wednesday.

Hidehiko Nishiyama, a spokesman for the Nuclear and Industrial Safety Agency, said the move is considered with the aim to stop a possible hydrogen explosion "in advance" and that it does not mean there is an "immediate danger."

The nitrogen injection process is expected to take several days, and may lead to the release of radioactive substances in the air.....

Japan: Radiation safety levels set for fish

AP

Wednesday, 6 April 2011 The Independent

The Government set its first radiation safety standards for fish yesterday after the country's tsunami-ravaged nuclear plant reported radioactive contamination in nearby seawater measuring at several million times the legal limit.

The plant operator insisted that the radiation will rapidly disperse and that it poses no immediate danger.

But an expert said exposure to the highly concentrated levels near the Fukushima Dai-ichi plant could cause immediate injury and that the leaks could result in residual contamination of the sea in the area. The new levels, coupled with reports that radiation was building up in fish, led the government to create an acceptable radiation standard, which officials said could change. Some fish caught last Friday would have exceeded the new limit.

<http://english.kyodonews.jp/news/2011/04/83542.html>

TEPCO to inject nitrogen in reactor no.1 to prevent explosion

Parenthèse:

The National Federation of Fisheries Cooperatives Associations lodged a protest with TEPCO and the Ministry of Economy, Trade and Industry on Wednesday, saying that the dumping of contaminated water into the sea without any prior consultation with fishermen was an "outrage."

The group also called for the dumping of contaminated water and the leakage of highly polluted water from the plant to be halted so as to prevent Japan's fishing industry from "perishing."

<http://english.kyodonews.jp/news/2011/04/83537.html>

evacuation of women and babies..

<http://english.kyodonews.jp/news/2011/04/83538.html>

Gov't reviewing radiation exposure levels used for evacuation

TOKYO, April 6, Kyodo

The government is reviewing radiation exposure levels currently used to designate an evacuation zone around the Fukushima Daiichi nuclear plant, as the nuclear crisis triggered by last month's massive earthquake and tsunami continues to unfold, its top spokesman said Wednesday.

"The current standards represent safety in the event of absorbing a huge amount of radiation in a short period," Chief Cabinet Secretary Yukio Edano said at a news conference, noting that **some changes may be necessary as residents nearby the plant are at risk of absorbing radiation over an extended period.**

Currently, the government says that outside radiation levels over 50 millisieverts require evacuation, and advises residents to remain indoors when levels exceed 10 millisieverts.

Based on these figures, the government has ordered residents within a 20 kilometer-radius of the nuclear plant to evacuate and those in the 20-30 km zone to stay indoors.

<http://english.kyodonews.jp/news/2011/04/83604.html> :Govt reviewing exposure level for evacuation

...The Nuclear Safety Commission of Japan said it has advised the government to issue an evacuation order if there is a possibility of residents receiving a dose of 20 millisieverts over one year, up from the current limit of 1 millisievert per year.

In the event of emergencies, the International Commission on Radiological Protection is recommending that the highest planned residual dose over a year be in the range of 20 to 100 millisieverts.

Seiji Shiroya, a member of the safety commission, said at a news conference that the international organization's recommendation will be used as a reference point to possibly toughen the country's present permissible radiation exposure levels.

.. The government also decided to allow residents of areas within the zone to return home for a short time possibly around next Monday, one month after the catastrophic quake.

<http://english.kyodonews.jp/news/2011/04/83613.html>

Tokyo Electric Power Co. on Wednesday started work to inject nitrogen into one of the reactors at the crippled Fukushima Daiichi nuclear power complex to reduce the potential risk of a hydrogen explosion,....

According to estimates by TEPCO announced Wednesday, 25 percent of the nuclear fuel rods have been damaged at the No. 3 reactor. The company earlier said that 70 percent of the No. 1 reactor's fuel rods and 30 percent of the No. 2 reactor's fuel rods have been damaged.

Nishiyama said past hydrogen explosions have likely occurred due to hydrogen accumulation caused by the reaction of melted fuel rods' zirconium with steam from the coolant water. But now there is concern that hydrogen could accumulate in the No. 1 reactor under a different process involving radiation-induced decomposition of water into hydrogen and oxygen.

In announcing TEPCO's decision to inject nitrogen into the reactor's containment vessel, an operation approved by the government, the nuclear agency said that **radioactive leaks are "unlikely to significantly rise"** even if the pressure inside the vessel increases as a result of the injection.

Nishiyama said that he also expects nitrogen to be injected into the Nos. 2 and 3 reactors in the future.

Areva's German Offices Raided by Prosecutors in Bribery Probe

By Karin Matussek - Apr 6, 2011 1:28 PM GMT+0200 Wed Apr 06 11:28:52 GMT 2011

<http://www.bloomberg.com/news/2011-04-06/areva-s-german-offices-raided-by-prosecutors-in-bribery-probe.html>

German offices of [Areva SA \(CED\)](#), the world's largest supplier of nuclear equipment and services, were raided by prosecutors in a probe over possible bribery payments.

Eight suspects, including five current and former Areva employees are being investigated over bribery and breach of trust allegations, prosecutors in Nuremberg, [Germany](#), said in an e-mailed statement today. The suspects may have transferred company money to slush funds abroad to "get competitive advantages," prosecutors said.

Prosecutors searched offices of the Areva NP unit in Erlangen, Germany, and an archive in the town of Offenbach yesterday, the company said in an e-mailed statement. Areva is cooperating and the probe isn't directed at the company, it said. The alleged actions may have been harmful to the company, Areva said.

Areva rivals including [Siemens AG \(SIE\)](#) and Alstom SA, have both been caught up in European bribery probes. **Siemens agreed to pay \$1.6 billion to settle bribery allegations in the U.S.** and Germany in 2008 and three U.K. Alstom executives were arrested last year in a separate probe there.

Investigators yesterday raided 31 homes and offices in Germany and the [Czech Republic](#), prosecutors said. Three suspects are consultants who may have helped the Areva employees in the alleged actions, prosecutors said.

No More Storage Space

Highly radioactive water in the basement of Reactor 2's turbine building needs to be removed, but there is no place for it. To make room, less radioactive water from the surge tanks is being drained into the sea. Last week, radioactive water from two condensate storage tanks was moved to these tanks.

Water Pouring Into Sea From Leak

Highly radioactive water is pouring into the sea from a leak in a pit. Concrete and other materials poured into the pit failed to stop the leak. Dye poured into the sea water tunnel near the turbine building did not reveal the tunnel as the source of the leak.

Diesel Generators Endangered

Parts of the turbine buildings at units 5 and 6 are flooded. To prevent diesel generators in the buildings from being damaged, the low-level radioactive water is being drained into the sea.

From Beyond Nuclear: **NYT reports new threats**

The [New York Times](#) has obtained a copy of a confidential document prepared by the US Nuclear Regulatory Commission's oversight team of the Fukushima Dai-Ichi nuclear power plant disaster. The nuclear hazard assessment warns of an increasingly complicated path towards restoring cooling and regaining control of the severely damaged reactor systems in four of the six units. New threats of more

hydrogen gas explosions and further damage to the reactors from water laden reactor buildings from more earthquake aftershocks may be increasing.

One of the most disturbing news story accounts taken from the NRC document states:

"The document also suggests that fragments or particles of nuclear fuel from spent fuel pools above the reactors were blown "up to one mile from the units," and that pieces of highly radioactive material fell between two units and had to be "bulldozed over," presumably to protect workers at the site. The ejection of nuclear material, which may have occurred during one of the earlier hydrogen explosions, may indicate more extensive damage to the extremely radioactive pools than previously disclosed."

April 6, 2011 |

[The New York Times has reported](#) that the stress from large quantities of emergency cooling water in Fukushima Daiichi reactor blocks could exacerbate the violent force exerted by powerful aftershocks, further risking breach of vital containment structures holding back the motherlode of radioactivity from escaping into the environment. Meanwhile, nearly a month after the March 11 earthquake and tsunami, police are at long last entering the 12 mile radius radiological evacuation zone, in search of 4,200 missing persons.

.. After the company successfully stopped leakage of highly radioactive water into the sea from a cracked pit Wednesday, it detected a temporary rise in the level of tainted water in an underground trench connected to the No. 2 reactor building, from which the toxic liquid is believed to originate.

Hidehiko Nishiyama, a spokesman for the nuclear regulatory body, said the water level, which rose about 4 centimeters and then returned to the previous level, suggests that **highly radioactive water may have begun leaking again from somewhere else** and said that TEPCO was expected to boost monitoring of seawater radiation levels...

Problems With Radioactive Water at the Plant

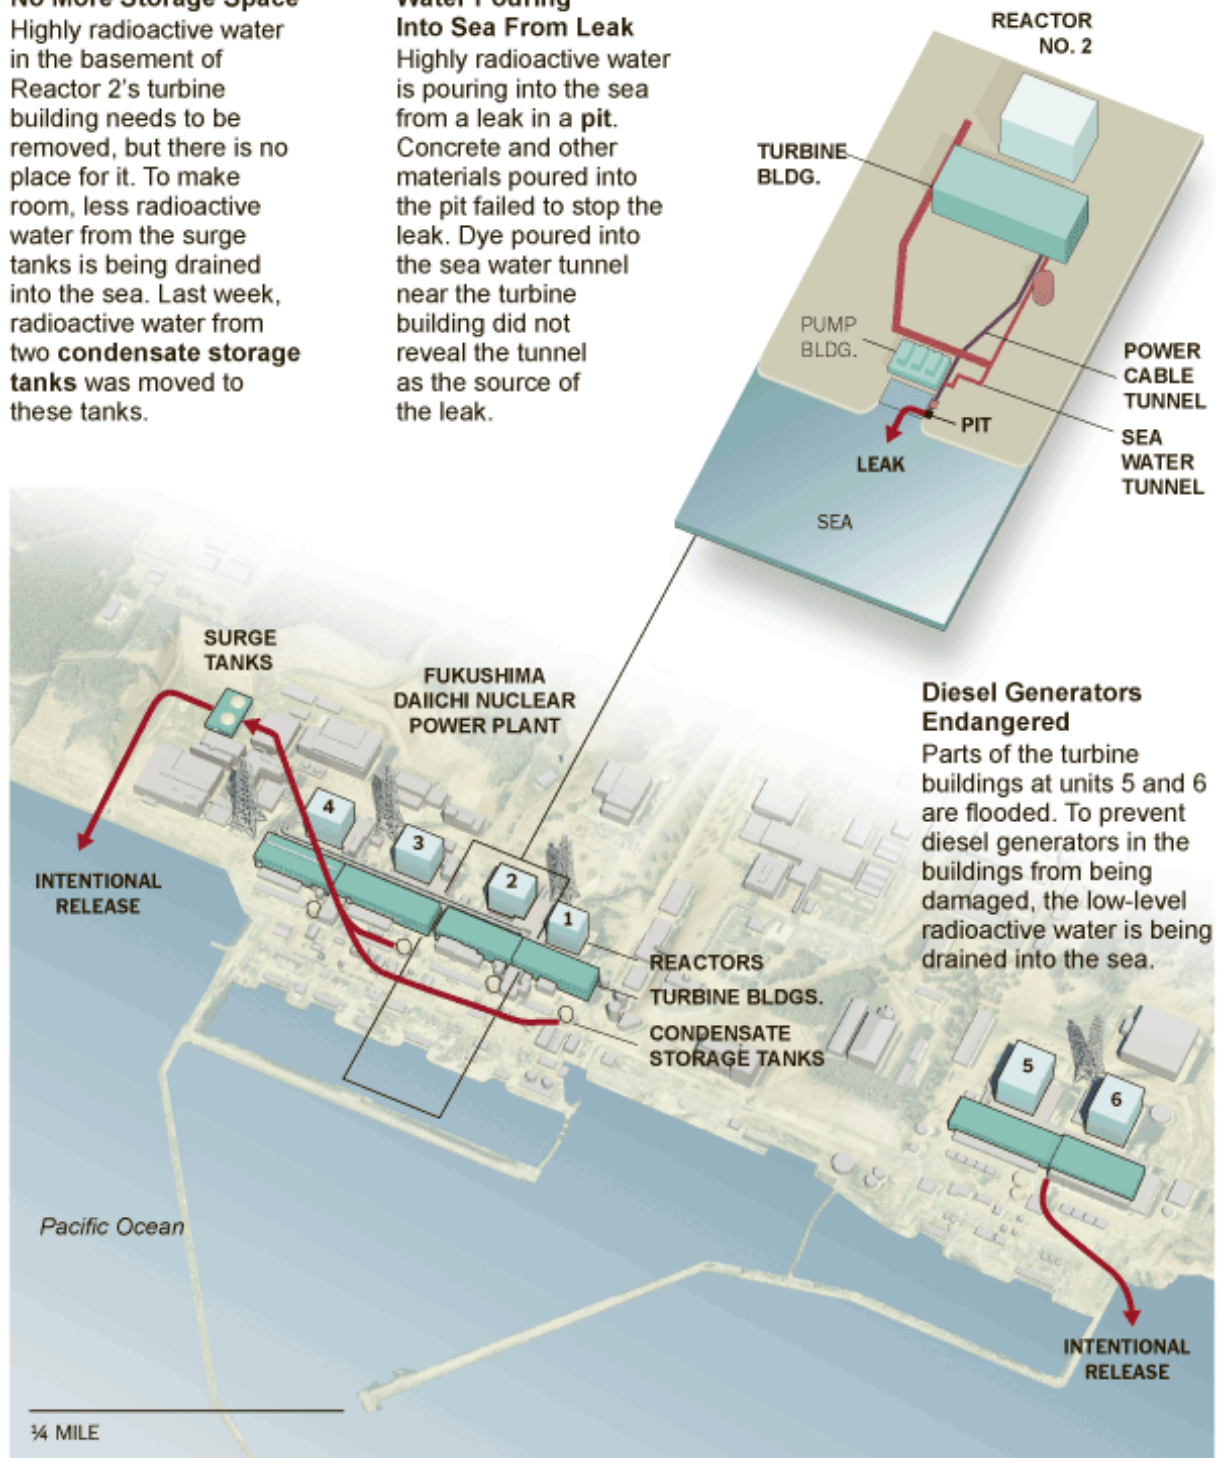

The Tokyo Electric Power Company is dealing with problems created by the buildup of radioactive water at its damaged nuclear power plant. Some of it is leaking, and the company has run out of space to store it.

No More Storage Space

Highly radioactive water in the basement of Reactor 2's turbine building needs to be removed, but there is no place for it. To make room, less radioactive water from the surge tanks is being drained into the sea. Last week, radioactive water from two condensate storage tanks was moved to these tanks.

Radioactive water spilled from pools holding spent nuclear fuel rods at the Onagawa power plant in Miyagi Prefecture following the strong earthquake late Thursday, the nuclear safety agency said Friday....

Toshiba proposes decommissioning 4 reactors in 10 years

TOKYO, April 8, Kyodo

Toshiba Corp. has proposed decommissioning four troubled nuclear reactors at the Fukushima Daiichi power station in about 10 years, much shorter than the 14 years that was needed to dismantle the Three Mile Island nuclear power plant in the United States, industry sources said Friday.

Toshiba, one of the two Japanese reactor makers, filed the proposal with Tokyo Electric Power Co., the operator of the Fukushima plant, and the Ministry of Economy, Trade and Industry, after compiling it with U.S. nuclear energy firms including its subsidiary Westinghouse Electric Co., according to the sources.

Toshiba believes it can rely on the U.S. firms' expertise from the 1979 Three Mile Island accident to decommission the Fukushima reactors.

According to the proposal, it will take about 10 years to remove the fuel rods in the containers and the spent nuclear fuel rods in the storage pools from the four reactors, to demolish various facilities there and to improve soil conditions.

Another Japanese reactor maker Hitachi Ltd., in a tie-up with General Electric Co. of the United States, is expected to file its own proposal, the sources said.

Tokyo Electric and METI are expected to look into those proposals by Toshiba and Hitachi before actually moving to dismantle the reactors.

The four reactors were crippled due to the March 11 earthquake and subsequent tsunami.

In Japan, Chubu Electric Power Co. is currently working on decommissioning two reactors at the Hamaoka nuclear power plant in Omaezaki, Shizuoka Prefecture, to have it completed by March 2037.

Radioactive materials spread around northern hemisphere in 2 weeks

VIENNA, April 7, Kyodo

Radioactive materials released from Japan's crippled Fukushima Daiichi nuclear power plant had spread around the entire northern hemisphere in the two weeks following the March 11 quake and tsunami disaster, a Vienna-based international nuclear watchdog said Thursday.

The Preparatory Commission for the Comprehensive Nuclear-Test-Ban Treaty Organization said minute traces of radioactive substances spread around the hemisphere by around March 25 after moving across the Pacific Ocean and other places. It said the amounts of such substances were far below levels that could affect human health.

The organization runs 63 monitoring stations around the world, including one in Takasaki, Gunma Prefecture in Japan. The Takasaki station detected radioactive substances on March 12, followed by detection in eastern Russia on March 14 and in the west coast of the United States two days later. The radioactive materials then crossed the Atlantic and reached Iceland on March 22, it said.

According to a simulation by a German research institute, a path of the radioactive materials involved moving from Fukushima to the United States on air currents before they were dispersed from northern Canada to the Arctic Sea to spread around the hemisphere.

Some produce near Fukushima plant to be allowed for shipments

TOKYO, April 8, Kyodo

The government will allow shipments of some produce from areas near the crippled Fukushima Daiichi nuclear power plant as they have been proved to be safe enough to consume, its top spokesman said Friday.

The restrictions on raw milk from Kitakata and several other municipalities in Fukushima Prefecture, and spinach and "kakina" leafy vegetable in Gunma Prefecture will be lifted, Chief Cabinet Secretary Yukio Edano said at a news conference.

The government had restricted shipments of some farm products from four prefectures following the release of radioactive particles from the tsunami-stricken nuclear plant.

The government, however, changed the way in which it applies such restrictions earlier this week, now imposing them on a town-by-town basis and making it a condition that each product will not be banned from being shipped if radioactivity data stay below safety limits for a third straight week. But since they keep on changing the safety limits to "suit" the situation, what is the value of such limits ?

The government, meanwhile, will restrict farmers from planting rice near the nuclear complex, which has been facing the emergency situation since the March 11 earthquake and tsunami.

If radioactivity levels higher than tentative safe limits set by the health ministry are detected in their rice, Edano said the government plans to pay them compensation.

= update nuclear facilities friday night (after latest shock)

TEPCO begins building steel wall, fence to prevent sea contamination

TOKYO, April 9, Kyodo

The operator of a crippled Fukushima nuclear power station started Saturday to install a steel wall and fence to prevent more water containing radioactive substances from seeping into the Pacific Ocean.

Tokyo Electric Power Co. plans to plug a seawater intake connected to the No. 2 reactor of the Fukushima Daiichi complex with seven steel sheets and a 120-meter-wide curtain-like fence near the intake and two other locations nearby.

The company already stopped the leakage of water contaminated with radioactive materials from near the intake Wednesday. But it went with the construction of the steel sheet wall and the so-called silt fence to allay environmental concerns that have been raised domestically and internationally.

Radioactive iodine reading was 63,000 times the legal limit in seawater near the intake a day after contaminated water stopped leaking into the sea.

Along with efforts to stop the leakage of toxic water, TEPCO also released about 9,000 tons of water containing relatively low-level radioactive materials into the Pacific, saying the massive amount of such water in the premises slowed the work to get the plant under control.

Japanese Workers Braved Radiation for a Temp Job

By HIROKO TABUCHI, New York Times, April 9 2011

<http://www.nytimes.com/2011/04/10/world/asia/10workers.html>

KAZO, Japan — The ground started to buck at the Fukushima Daiichi nuclear power plant, and Masayuki Ishizawa could scarcely stay on his feet. Helmet in hand, he ran from a workers' standby room outside the plant's No. 3 reactor, near where he and a group of workers had been doing repair work. He saw a chimney and crane swaying like weeds. Everybody was shouting in a panic, he recalled.

Mr. Ishizawa, 55, raced to the plant's central gate. But a security guard would not let him out of the complex. A long line of cars had formed at the gate, and some drivers were blaring their horns. "Show me your IDs," Mr. Ishizawa remembered the guard saying, insisting that he follow the correct sign-out procedure. And where, the guard demanded, were his supervisors? "What are you saying?" Mr. Ishizawa said he shouted at the guard. He looked over his shoulder and saw a dark shadow on the horizon, out at sea, he said. He shouted again: "Don't you know a tsunami is coming?"

Mr. Ishizawa, who was finally allowed to leave, is not a nuclear specialist; he is not even an employee of the Tokyo Electric Power Company, the operator of the crippled plant. He is one of thousands of untrained, itinerant, temporary laborers who handle the bulk of the dangerous work at nuclear power plants here and in other countries, lured by the higher wages offered for working with radiation. **Collectively, these contractors were exposed to levels of radiation about 16 times as high as the levels faced by Tokyo Electric employees last year,** according to **Japan's** Nuclear and Industrial Safety Agency, which regulates the industry. These workers remain vital to efforts to contain the nuclear crisis at the Fukushima nuclear plants.

They are emblematic of Japan's two-tiered work force, with an elite class of highly paid employees at top companies and a subclass of laborers who work for less pay, have less job security and receive fewer benefits. Such labor practices have both endangered the health of these workers and undermined safety at Japan's 55 nuclear reactors, critics charge.

"This is the hidden world of nuclear power," said Yuko Fujita, a former physics professor at Keio University in Tokyo and a longtime campaigner for improved labor conditions in the nuclear industry. "Wherever there are hazardous conditions, these laborers are told to go. It is dangerous for them, and it is dangerous for nuclear safety."

Of roughly 83,000 workers at Japan's 18 commercial nuclear power plants, 88 percent were contract workers in the year that ended in March 2010, the nuclear agency said. **At the Fukushima Daiichi plant, 89 percent of the**

10,303 workers during that period were contractors. In Japan's nuclear industry, the elite are operators like Tokyo Electric and the manufacturers that build and help maintain the plants like Toshiba and Hitachi. But under those companies are contractors, subcontractors and sub-subcontractors — with wages, benefits and protection against radiation dwindling with each step down the ladder.

Interviews with about a half-dozen past and current workers at Fukushima Daiichi and other plants paint a bleak picture of workers on the nuclear circuit: battling intense heat as they clean off radiation from the reactors' drywells and spent-fuel pools using mops and rags, clearing the way for inspectors, technicians and Tokyo Electric employees, and working in the cold to fill drums with contaminated waste.

Some workers are hired from construction sites, and some are local farmers looking for extra income. Yet others are hired by local gangsters, according to a number of workers who did not want to give their names.

They spoke of the constant fear of getting fired, trying to hide injuries to avoid trouble for their employers, carrying skin-colored adhesive bandages to cover up cuts and bruises.

In the most dangerous places, current and former workers said, radiation levels would be so high that workers would take turns approaching a valve just to open it, turning it for a few seconds before a supervisor with a stopwatch ordered the job to be handed off to the next person. Similar work would be required at the Fukushima Daiichi plant now, where the three reactors in operation at the time of the earthquake shut down automatically, workers say.

"Your first priority is to avoid pan-ku," said one current worker at the Fukushima Daiichi plant, using a Japanese expression based on the English word puncture. Workers use the term to describe their dosimeter, which measures radiation exposure, from reaching the daily cumulative limit of 50 millisieverts. "Once you reach the limit, there is no more work," said the worker, who did not want to give his name for fear of being fired by his employer.

Takeshi Kawakami, 64, remembers climbing into the spent-fuel pool of the No. 1 reactor at the Fukushima Daiichi plant during an annual maintenance shutdown in the 1980s to scrub the walls clean of radiation with brushes and rags. All workers carried dosimeters set to sound an alarm if exposure levels hit a cumulative dose limit; Mr. Kawakami said he usually did not last 20 minutes. "It was unbearable, and you had your mask on, and it was so tight," Mr. Kawakami said. "I started feeling dizzy. I could not even see what I was doing. I thought I would drown in my own sweat."

Since the mid-1970s, about 50 former workers have received workers' compensation after developing leukemia and other forms of cancer. Health experts say that though many former workers are

experiencing health problems that may be a result of their nuclear work, it is often difficult to prove a direct link. Mr. Kawakami has received a diagnosis of stomach and intestinal cancer.

News of workers' mishaps turns up periodically in safety reports: one submitted by Tokyo Electric to the government of Fukushima Prefecture in October 2010 outlines an accident during which a contract worker who had been wiping down a turbine building was exposed to harmful levels of radiation after accidentally using one of the towels on his face. In response, the company said in the report that it would provide special towels for workers to wipe their sweat.

Most day workers were evacuated from Fukushima Daiichi after the March 11 earthquake and tsunami, which knocked out the plant's power and pushed some of the reactors to the brink of a partial meltdown.

Since then, those who have returned have been strictly shielded from the news media; many of them are housed at a staging ground for workers that is off limits to reporters. But there have been signs that such laborers continue to play a big role at the crippled power plant.

The two workers who were injured two weeks ago when they stepped in radioactive water were subcontractor employees. As of Thursday, 21 workers at the plant had each been exposed to cumulative radiation levels of more than 100 millisieverts, or the usual limit set for nuclear plant workers during an emergency, according to Tokyo Electric. (That limit was raised to 250 millisieverts last month.)

The company refused to say how many contract workers had been exposed to radiation. Of roughly 300 workers left at the plant on Thursday, 45 were employed by contractors, the company said.

Day laborers are being lured back to the plant by wages that have increased along with the risks of working there. Mr. Ishizawa, whose home is about a mile from the plant and who evacuated with the town's other residents the day after the quake, said he had been called last week by a former employer who offered daily wages of about \$350 for just two hours of work at the Fukushima Daiichi plant — more than twice his previous pay. Some of the former members of his team have been offered nearly \$1,000 a day. Offers have fluctuated depending on the progress at the plant and the perceived radiation risks that day. So far, Mr. Ishizawa has refused to return.

Working conditions have improved over the years, experts say. While exposure per worker dropped in the 1990s as safety standards improved, government statistics show, the rates have been rising since 2000, partly because there have been more accidents as reactors age. Moreover, the number of workers in the industry has risen, as the same tasks are carried out by more employees to reduce individual exposure levels.

Highly radioactive water in nuke plant set to be moved for storage

High radiation dosage at the level of several hundreds of milisieverts per hour has been observed at an area between the Nos. 2 and 3 reactors and the west side of the No. 3 reactor, suggesting the debris may be emitting radiation, TEPCO said, adding that work efficiency can be secured even in such touchy conditions by using the remote-control system.

<http://english.kyodonews.jp/news/2011/04/84371.html>

20km zone off-limits

...As for the 20- to 30-km area for residents to stay indoors, Fukuyama said the government is considering expanding it as "some areas outside of the 30-km zone have seen the cumulative amount of radiation on the rise, depending on the wind."

http://balisescriirad.free.fr/risques_en_france_v5.pdf

<http://english.kyodonews.jp/news/2011/04/84522.html>

...Plant operator Tokyo Electric Power Co. is set to start pumping out some 700 tons of highly polluted water from an underground trench to a nearby storage area it secured in the No. 2 reactor turbine building, and the nuclear regulatory agency said in the morning that it had permitted the move after confirming the safety of the plan.

Water containing radioactive substances has been found in the basements of the Nos. 1 to 3 reactor turbine buildings, as well as in tunnel-like trenches connected to them. Transferring the water, totaling some 60,000 tons, to nearby tanks and other places is seen as vital to move ahead with work to restore the damaged key cooling functions of the reactors...

. The nuclear agency said that a total of 9,070 tons of liquid has been disposed of into the sea since April 4, in addition to about 1,300 tons of contaminated groundwater from near the No. 5 and No. 6 reactors..

On Monday, TEPCO also continued to inject nitrogen, an inert gas, into the No. 1 reactor to reduce the potential risks of hydrogen explosion, while continuing work to install enclosing materials in the sea to prevent a further spread of highly radioactive water that had already seeped from the plant.

URGENT: Japan to expand evacuation areas near crippled nuclear plant

TOKYO, April 11, Kyodo

The government will expand evacuation districts near the crippled Fukushima Daiichi nuclear power plant, its top spokesman said Monday.

With the crisis at the plant dragging out, some municipalities within a 20- to 30-kilometer radius of the power plant will now be designated as additional evacuation areas, Chief Cabinet Secretary Yukio Edano said at a news conference.

Residents in the radius are at the moment urged to stay indoors.

Japan to expand evacuation areas near crippled nuclear plant

TOKYO, April 11, Kyodo

The government will expand evacuation districts near the crippled Fukushima Daiichi nuclear power plant, its top spokesman said Monday.

With the crisis at the plant dragging on, some municipalities within a 20- to 30-kilometer radius of the power plant will now be designated as additional evacuation areas, Chief Cabinet Secretary Yukio Edano said at a news conference.

The government had earlier ordered residents within the 20-km radius of the power station to evacuate and those in the 20-30 km zone to stay indoors after the plant was hit by a deadly earthquake and tsunami on March 11.

The government changed the radiation exposure level which had been used to determine the evacuation zone.

Previously, the government said that outside radiation levels of over 50 millisieverts require evacuation, and advises residents to remain indoors when levels exceed 10 millisieverts.

From now on, it will issue an evacuation order if there is a possibility of residents receiving a dose of 20 millisieverts during the course of a year.

In the event of an emergency, the International Commission on Radiological Protection is recommending also that the highest planned residual dose over one year be in the range of 20 to 100 millisieverts.

The municipalities which will be part of the new evacuation zone include Katsurao, Namie and Iitate, all located in Fukushima Prefecture.

Residents in these municipalities will be expected to move to different areas within one month, Edano said.

water injection temporarily stopped after quake

Japan may raise nuke accident severity level to highest 7 from 5

TOKYO, April 12, Kyodo <http://english.kyodonews.jp/news/2011/04/84721.html>

The Nuclear Safety Commission of Japan released a preliminary calculation Monday saying that the crippled Fukushima Daiichi nuclear plant had been releasing up to 10,000 terabecquerels of radioactive materials per hour at some point after a massive quake and tsunami hit northeastern Japan on March 11.

The disclosure prompted the government to consider raising the accident's severity level to 7, the worst on an international scale, from the current 5, government sources said. **The level 7 on the International Nuclear Event Scale has only been applied to the 1986 Chernobyl catastrophe.**

The current provisional evaluation of 5 is at the same level as the Three Mile Island accident in the United States in 1979.

According to an evaluation by the INES, level 7 accidents correspond with a release into the external environment radioactive materials equal to more than tens of thousands terabecquerels of radioactive iodine 131. One terabecquerel equals 1 trillion becquerels.

Haruki Madarame, chairman of the commission, which is a government panel, said it has estimated that the release of 10,000 terabecquerels of radioactive materials per hour continued for several hours.

The commission says the release has since come down to under 1 terabecquerel per hour and said that it is still examining the total amount of radioactive materials released.

The commission also released a preliminary calculation for the cumulative amount of external exposure to radiation, saying it exceeded the yearly limit of 1 millisieverts in areas extending more than 60 kilometers to the northwest of the plant and about 40 km to the south-southwest of the plant.

It encompasses the cities of Fukushima, Date, Soma, Minamisoma, and Iwaki, which are all in Fukushima Prefecture, and some areas including the town of Hirono in the prefecture.

Within a 20-km exclusion zone set by the government, the amount varied from under 1 millisieverts to 100 millisieverts or more, and in the 20-30 km radius ring where residents are asked to stay indoors, it came to under 50 millisieverts.

The commission used the System for Prediction of Environmental Emergency Dose Information to calculate the spread of radiation.

Japan raises nuke accident severity level to highest 7 from 5

TOKYO, April 12, Kyodo

Japan on Tuesday raised the severity level of the accident at the crippled Fukushima Daiichi nuclear plant to the maximum 7 on an international scale, up from the current 5 and matching that of the 1986 Chernobyl catastrophe.

The previous evaluation of 5 on the International Nuclear Event Scale provisionally set by the Nuclear and Industrial Safety Agency, a body under the Ministry of Economy, Trade and Industry, was at the same level as the Three Mile Island accident in the United States in 1979.

While raising the level for the accident, the agency said, however, that the amount of radioactive materials released into the external environment from the nuke plant is estimated to be about 10 percent of the amount released in the Chernobyl catastrophe.

The decision comes after the release of a preliminary calculation Monday by the Nuclear Safety Commission of Japan, which said the crippled nuclear plant was releasing up to 10,000 terabecquerels of radioactive materials per hour at one point after a magnitude 9.0 earthquake and subsequent tsunami hit northeastern Japan on March 11.

Level 7 accidents on the INES correspond to the release into the external environment of radioactive materials equal to more than tens of thousands of terabecquerels of radioactive iodine 131. One terabecquerel equals 1 trillion becquerels.

The agency estimated that up to 370,000 terabecquerels of radioactive materials had been released in the air while the commission said it estimated 630,000 terabecquerels, both far exceeding the criteria for level

7.

Haruki Madarame, chairman of the commission, said earlier it estimates the release of 10,000 terabecquerels of radioactive materials per hour continued for several hours.

The commission says the release has since come down to under 1 terabecquerel per hour and that it is still examining the total amount of radioactive materials released.

It also released a preliminary calculation for the cumulative amount of external exposure to radiation, saying it exceeded the yearly limit of 1 millisievert in areas extending more than 60 kilometers northwest of the plant and about 40 km south-southwest of the plant.

The areas encompass the cities of Fukushima, Date, Soma, Minamisoma and Iwaki and part of the town of Hirono, all in Fukushima Prefecture.

Within a 20-km exclusion zone set by the government, the amount varied from under 1 millisievert to 100 millisieverts or more, and in the 20-30 km ring where residents are asked to stay indoors, it came to under 50 millisieverts.

The commission used the System for Prediction of Environmental Emergency Dose Information to calculate the spread of radiation.

==Kyodo

Japan apologizes after raising nuclear crisis level to highest

TOKYO, April 12, Kyodo

Top government spokesman Yukio Edano apologized on Tuesday to residents near the crippled Fukushima Daiichi nuclear power plant and the global community after Japan raised the severity rating of its nuclear crisis to the highest level of 7.

Despite the changed assessment that puts it on a par with the 1986 Chernobyl catastrophe, the chief Cabinet secretary told reporters, "Unlike in the case of Chernobyl, we have not seen cases of direct damage to health because of the accident."

The Fukushima accident, triggered by the March 11 magnitude-9.0 earthquake and tsunami, is now registered as 7, up from the previous evaluation of 5, on the International Nuclear Event Scale provisionally set by the government's Nuclear and Industrial Safety Agency.

Edano promised that the government will place priority on taking steps to erase health hazards to the people and to contain the effects of the accident on products amid rumors about the safety of food items.

To support his point that farm products from Fukushima Prefecture are safe, the chief Cabinet secretary attended an exhibit of farm produce from the Fukushima city of Iwaki held in Tokyo's Shimbashi district.

Eating strawberries and tomatoes, Edano said, "Food sold on the market is all safe" and urged the public to help Fukushima by buying its products.

URGENT: Radiation leakage may eventually exceed that of Chernobyl: TEPCO

TOKYO, April 12, Kyodo

The operator of the crippled Fukushima nuclear plant said Tuesday that it is concerned that radiation leakage at the plant could eventually exceed that of the 1986 Chernobyl catastrophe.

"The radiation leak has not stopped completely and our concern is that the amount of leakage could eventually reach that of Chernobyl or exceed it," an official from the Tokyo Electric Power Co. said.

Meanwhile, the Nuclear and Industrial Safety Agency said that most of the radioactive material released in the air from the crippled Fukushima Daiichi nuclear plant came from the No. 2 reactor damaged by an explosion on March 15.

At 6:10 a.m. on March 15, part of the reactor's containment vessel was damaged following an apparent hydrogen explosion. Massive amounts of radioactive substances are believed to have been released from the suppression pool of the reactor, the agency said.

Japan on Tuesday raised the severity level of the accident at the plant to the maximum 7 on an international scale, up from the current 5 and matching that of the Chernobyl disaster in the former Soviet republic of Ukraine.

The agency said, however, that the amount of radioactive materials released from the nuke plant is estimated to be about 10 percent of the amount released in the Chernobyl accident.

?????

<http://www.independent.co.uk/news/world/asia/japan-nuclear-crisis-severity-level-upgraded-2266594.html>

...He said the amount of radiation leaking from the Fukushima Dai-ichi nuclear plant was around 10 percent of the Chernobyl accident.

However, Tokyo Electric Power Co., the operator of the plant, is still estimating the total amount of radioactive material that might be released by the accident, said company spokesman Junichi Matsumoto.

He acknowledged that, if leaks continue, the amount of radioactivity released might eventually exceed the amount emitted by Chernobyl...

Radioactive strontium detected more than 30 km from Fukushima plant

TOKYO, April 12, Kyodo

Minute amounts of radioactive strontium have been detected in soil and plants in Fukushima Prefecture beyond the 30-kilometer zone around the crippled Fukushima Daiichi Nuclear Power Station, the science ministry said Tuesday.

It is the first time that radioactive strontium has been detected since the Fukushima plant began leaking radioactive substances after it was severely damaged by the March 11 earthquake and tsunami.

There is no safety limit set by the government for exposure to strontium, but the amount found so far is extremely low and does not pose a threat to human health, the Education, Culture, Sports, Science and Technology said.

Experts, however, expressed concern that the accumulation of strontium could have adverse health effects. When strontium enters the human body, it tends to accumulate in bones and is believed to cause bone cancer and leukemia.

Samples of soil and plants were taken March 16 to 19 from a number of locations in Fukushima Prefecture.

The government has designated the area within a 20-km radius of the plant as an evacuation zone, while people residing in areas in the 20- to 30-km ring have been asked to remain indoors. On Monday, the government expanded the evacuation zone to some municipalities beyond the 20-km radius where residents will evacuate in around a month.

Japan ups Fukushima nuke crisis severity to 7, same as Chernobyl

TOKYO, April 12, Kyodo

Japan on Tuesday raised the severity level of the ongoing emergency at the crippled Fukushima Daiichi nuclear power plant from level 5 to the maximum 7 on an international scale, **recognizing that the tsunami-caused accident matches the world's worst nuclear catastrophe in 1986 at Chernobyl.**

The government's Nuclear and Industrial Safety Agency upgraded its provisional evaluation based on an estimate that radioactive materials far exceeding the criteria for level 7 have so far been released into the external environment, but added that the release from the Fukushima plant is about 10 percent of that from the former Soviet nuclear plant.

The nuclear regulatory agency under the Economy, Trade and Industry Ministry and the Nuclear Safety Commission of Japan, a government panel, said that **between 370,000 and 630,000 terabecquerels of radioactive materials have been emitted into the air from the Nos. 1 to 3 reactors of the plant.**

Level 7 accidents on the International Nuclear Event Scale correspond to the release into the external environment of radioactive materials equal to more than tens of thousands of terabecquerels of radioactive iodine 131. One terabecquerel equals 1 trillion becquerels.

Chief Cabinet Secretary Yukio Edano emphasized that the raising of the severity level does not mean the situation at the Fukushima plant is "worsening."

The top government spokesman said the latest assessment is simply based on data which are more accurate than the time it made its previous assessments.

The plant operator Tokyo Electric Power Co. offered an apology to the public for being still unable to stop the radiation leakage, pointing to the possibility that the total emission of radioactive substances could eventually surpass that of the Chernobyl incident.

A considerable amount of radioactive materials emitted is believed to originate from the plant's No. 2 reactor, whose containment vessel's pressure suppression chamber was damaged by an explosion on March 15, said Kenkichi Hirose, a Cabinet Office adviser serving for the safety commission, at a news conference.

"Our estimates suggest the amount of radioactive materials released into the air sharply rose on March 15 and 16 after abnormalities were detected at the No. 2 reactor," Hirose said. "The cumulative amount of leaked radiation has been gradually on the rise, but we believe the current emission level is significantly low."

The safety commission said it estimates the release has come down to under 1 terabecquerel per hour.

Japan believes the Fukushima crisis, triggered by the devastating March 11 earthquake and ensuing tsunami, is different from the Chernobyl accident in many ways, said Hidehiko Nishiyama, a spokesman for the nuclear agency.

As examples, Nishiyama said no one in Fukushima has died from acute diseases caused by exposure to massive amounts of radiation, compared with about 30 in the accident that happened in the former Soviet Union, and that the reactors themselves did not explode as in Chernobyl.

"Even though some amount of radiation keeps leaking from reactors and their containment vessels, **they are not totally destroyed and are functioning**," Nishiyama said. ??????

Tokyo Electric Power Vice President Sakae Muto echoed the view that the Fukushima case is "considerably different" from Chernobyl "in terms of how radiation has been emitted and how much it has gone out."

Muto said the company takes seriously the fact that the severity level had been raised and apologized for the troubles at the plant. However, he did not give a clear-cut answer to questions about how the utility evaluates the current situation or the prospects of the still-unfolding crisis.

Hirose of the Cabinet Office ruled out the possibility that the evacuation zone set by the government within 20 kilometers from the plant will be reviewed following the upgrading of the severity level.

Nishiyama said it took about a month to raise the severity level of the Fukushima contingency due to a delay in securing reliable monitoring data. On March 18, the agency had provisionally set the level at 5, the same as the Three Mile Island accident in the United States in 1979.

The provisional judgment will be finalized after examinations by a government panel of nuclear experts, Nishiyama said, adding that the government will further bolster radiation monitoring to collect data.

The INES only reflects radiation emitted into the air, and **Japan needs to independently assess the severity of the incident by also monitoring contamination levels in the sea and soil**, he said.

Earlier, the safety commission released a preliminary calculation for the cumulative amount of radiation, saying it has exceeded the yearly limit of 1 millisievert in areas extending more than 60 km northwest of the plant and about 40 km south-southwest of the plant.

Within the 20-km exclusion zone, the amount varied from under 1 millisievert to 100 millisieverts or more, and in the 20-30 km ring where residents are asked to stay indoors it came to nearly 50 millisieverts.

Workers start removing toxic water in level 7-rated nuke crisis

TOKYO, April 13, Kyodo

Workers at the disaster-hit Fukushima Daiichi nuclear power plant started Tuesday to remove highly radioactive water in the plant as part of efforts to bring an end to the nuclear crisis, which the government recognized as reaching the highest severity level of 7 on an international scale.

A series of aftershocks of the March 11 earthquake on Monday and Tuesday raised concerns over the plant conditions, but injecting water into the troubled Nos. 1 to 3 reactors, which is vital to keep the nuclear fuel inside cool, was not disrupted by the latest magnitude 6.3 quake at 2:07 p.m. Tuesday.

The aftershocks forced workers to temporarily evacuate, leading to a delay in the work to remove pools of highly radioactive water that is hampering efforts to restore the reactors' key cooling functions, lost in the March 11 massive quake and tsunami.

But from 7:30 p.m. Tuesday, Tokyo Electric Power Co., the plant operator, began pumping out some highly polluted water from an underground tunnel-like trench to a nearby storage area inside the No. 2 reactor's turbine building.

Some 700 tons are to be transferred to a "condenser" where in normal operations steam created from the reactor is converted into water. The operation is expected to take 40 hours.

Still there is a long road ahead to remove a total of some **60,000 tons of contaminated water**, found in the basements of the Nos. 1 to 3 reactor turbine buildings as well as the trenches connected to them, and to store it in nearby tanks and other areas.

Prime Minister Naoto Kan said Tuesday that situation of the troubled reactors is "improving step by step" and that the release of radioactive particles from the plant is declining.

However, the upgrading of the severity level of the Fukushima accident from 5 to 7, the same level as the world's worst nuclear catastrophe in 1986 in Chernobyl, further raises concerns over the disaster's impact on human health and environment.

Economy, Trade and Industry Minister Banri Kaieda told a press conference a large part of the radioactive materials release took place in the early days of the crisis when hydrogen explosions occurred, and that Tokyo Electric, known as TEPCO, is working hard to prevent a recurrence.

"As we have not been completely able to block radioactive substances from scattering, it is true that the amount of release would continue to increase...but we do not expect at this moment that the amount would drastically increase," Kaieda said.

While the strong aftershock on Monday resulted in the suspension of an operation to inject nitrogen into the No. 1 reactor to reduce the potential risks of hydrogen explosion, the government's Nuclear and Industrial Safety Agency said that the work resumed and was not affected in the Tuesday afternoon quake.

TEPCO, meanwhile, took 400 milliliters of water from the spent fuel pool of the No. 4 unit to check to what extent the spent nuclear fuel stored there is damaged.

There is a possibility that the fuel may have been temporarily exposed when the water level at the storage pool dropped following the March 11 disaster, but camera footage found that the water level now was enough to cover the fuel. But the temperature of the water was 90 degrees, much higher than the usual 20-30 degrees.

The firm has already estimated that 25-70 percent of the nuclear fuel rods in the Nos. 1-3 reactors have been damaged.

The No. 4 reactor, halted for a regular inspection before the quake, has had all of its fuel rods stored in the pool for the maintenance work.

Massive amounts of water have been poured into the reactors and their spent nuclear fuel pools as a stopgap measure to cool them down. **But pools of contaminated water have been detected in various parts of the nuclear complex on the Pacific coast, with some leaking into the sea, as an apparent side effect of the emergency measure.**

Kaieda admitted that safety measures required for reactors to cope with tsunami waves had not been sufficient, saying that authorities must "reconsider the basic planning" of Japan's nuclear plants which are currently located on the coastlines of the quake-prone country.

Meanwhile, TEPCO said that the latest quake on Tuesday did not affect the Fukushima Daiichi nuclear power plant, located near the Daiichi plant.

Edano aware in March that nuke crisis could be raised to worst level

TOKYO, April 13, Kyodo

Chief Cabinet Secretary Yukio Edano said Wednesday he was aware in late March of the possibility that the status of the ongoing nuclear crisis at the Fukushima Daiichi power plant could be raised to the worst level, but the decision did not come until later because of inconclusive data.

Japan's new assessment, raising the crisis to the highest level of 7 on an international scale, was announced Tuesday, about a month after a magnitude 9.0 earthquake and tsunami crippled the plant and caused radiation leaks, fueling widespread criticism that the government has acted belatedly.

The assessment now puts the situation at the Fukushima plant situation on a par with the 1986 Chernobyl catastrophe.

Edano told a news conference Wednesday that two government-related nuclear bodies said in late March that their crisis assessment estimates were based on radiation monitoring data from only three locations.

"The Nuclear and Industrial Safety Agency and the Nuclear Safety Commission of Japan said they could not vouch for the certainty of their estimates, so I told them to make a thorough, reliable analysis as soon as possible," said the top government spokesman, who added that he was informed Monday about the forthcoming change in assessment.

The government's nuclear agency on Tuesday upgraded its provisional evaluation based on an estimate that radioactive materials far exceeding the criteria for level 7 have so far been released into the external environment.

On the same day, **Seiji Shiroya of the nuclear commission, a government panel, said in a news conference that he was aware as of March 23 that the crisis might be elevated to level 7, but left the decision to the agency because the assessment was the agency's responsibility.**

On March 18, the agency provisionally set the level at 5, the same as the 1979 Three Mile Island accident in the United States.

Edano defended the way the government has handled the process leading up to Tuesday's announcement, saying, "We have repeatedly issued instructions to relevant entities to fully disclose various information."

He also said that Japan's safety standards will not immediately change as a result of the assessment upgrading because the level was based on additional analysis of existing data.

At the same time, the chief Cabinet secretary **admitted that a proper assessment could have been possible more quickly if more extensive radiation monitoring data had been collected earlier.**

"I believe we would have been able to make various decisions at an earlier stage if more monitoring of radioactive materials in the areas surrounding the plant had been conducted at more locations," Edano said.

TEPCO confirms damage to part of No. 4 unit's spent nuke fuel

TOKYO, April 13, Kyodo

Some of the spent nuclear fuel rods stored in the No. 4 reactor building of the crisis-hit Fukushima Daiichi power plant were confirmed to be damaged, but most of them are believed to be in sound condition, plant operator Tokyo Electric Power Co. said Wednesday.

The firm known as TEPCO said its analysis of a 400-milliliter water sample taken Tuesday from the No. 4 unit's spent nuclear fuel pool revealed the damage to some fuel rods in such a pool for the first time, as it detected higher-than-usual levels of radioactive iodine-131, cesium-134 and cesium-137.

The No. 4 reactor, halted for a regular inspection before last month's earthquake and tsunami disaster, had all of its 1,331 fuel rods stored in the pool for the maintenance work and the fuel was feared to have sustained damage from overheating.

The roof and the upper walls of the No. 4 reactor building have been blown away by a hydrogen explosion and damaged by fires since the disaster struck the plant. The water level in the spent fuel pool is believed to have temporarily dropped.

TEPCO plans to examine the condition of the plant's reactor buildings by deploying a small unmanned helicopter to see whether it is possible to extract spent fuel from pools.

Earlier in the day, the government's nuclear regulatory agency ordered TEPCO to check the quake resistance of reactor buildings at the Fukushima plant, which have been rocked by strong aftershocks from the magnitude-9.0 earthquake that wrecked the site and triggered tsunami on March 11.

The Nuclear and Industrial Safety Agency told the utility to immediately examine the buildings and consider reinforcement work if they are judged as not sufficiently quakeproof.

In addition to the No. 4 unit, the Nos. 1 and 3 reactor buildings have also been severely damaged by hydrogen explosions in the early days of the crisis.

"As strong aftershocks occur almost daily, we have to consider what will happen to buildings already damaged by blasts," said Hidehiko Nishiyama, a spokesman for the nuclear agency.

He acknowledged the difficulties involved in the work to reinforce the quake resistance of the buildings, where radiation levels are high, but said, "We must devise some ways." The agency urged TEPCO to report back to it on the matter as soon as possible.

Meanwhile, Yoko Komiyama, senior vice minister of health, labor and welfare, said Wednesday at a Diet session that a total of 22 workers at the plant have been exposed to radiation exceeding 100 millisieverts as of early Wednesday and that the highest level of exposure among them is 198.24 millisieverts.

Exposure to 100 millisieverts is the permissible level for nuclear plant workers dealing with an emergency, but the limit has been raised to 250 millisieverts for the ongoing crisis.

Workers continued Wednesday to remove highly radioactive water in the plant as part of efforts to put an end to the emergency, which is now acknowledged as one of the world's worst nuclear disasters.

TEPCO had pumped out 700 tons of highly polluted water by Wednesday evening from an underground tunnel-like trench to a "condenser," where in normal operations steam from the reactor is converted into water.

Eventually, the operator plans to remove a total of 60,000 tons of contaminated water, found in the basements of the Nos. 1 to 3 reactor turbine buildings as well as the trenches connected to them, and to store it in nearby tanks and other areas.

As a result of the operation, the level of highly radioactive water that had been filling up the trench connected to the No. 2 reactor's turbine building was lowered. Nishiyama said it will likely take several weeks before the tainted water removal operation ends.

The highly toxic water is believed to originate from the No. 2 reactor's core, where fuel rods have partially melted. The water, which has also affected other parts of the plant, is hampering efforts to restore the reactors' key cooling functions, lost in the March 11 earthquake and tsunami.

The nuclear agency also said TEPCO has installed three steel sheets near a seawater intake for the No. 2 reactor and set up "silt fence" curtain barriers near intakes for the Nos. 3-4 reactors at the six-reactor plant to block the spread of radioactive substances in water.

Massive amounts of water have been poured into the reactors and their spent nuclear fuel pools as a stopgap measure to cool them down at the Fukushima plant.

But pools of contaminated water have been detected in various parts of the nuclear complex on the Pacific coast, with some water leaking into the sea, as an apparent side effect of the emergency measure. TEPCO successfully stopped the leak of highly radioactive water from a cracked pit on April 6.

Fukushima evacuees demand compensation

<http://www.guardian.co.uk/world/2011/apr/13/japan-nuclear-plant-evacuees-compensation>

Residents and business owners in [Japan](#) who have been forced to leave their homes amid radiation fears on Wednesday demanded immediate damages from the company at the centre of the nuclear crisis.

About 20 people who have been evacuated from areas near the Fukushima Daiichi plant protested outside the Tokyo Electric Power Company (Tepco) headquarters, calling for a quick decision on possible compensation.

The company's president, Masataka Shimizu, apologised during a rare public appearance and said he would compensate the tens of thousands of people whose lives have been disrupted by the nuclear emergency.

Japanese media suggests other domestic utilities could be asked to help pay damages, an approach adopted in the aftermath of the Three Mile Island disaster in the US in 1979.

Shimizu and other Tepco executives bowed in apology and promised that cash payments were being prepared. Shimizu, whose handling of the world's worst nuclear accident since Chernobyl has been

widely criticised, said the firm would do its utmost to stabilise the stricken reactors and enable evacuees to rebuild their businesses.

Safety officials have raised the severity level of the crisis to a maximum seven – the same as Chernobyl – although the quantities of radiation at Fukushima are one-tenth of those released by the Soviet plant. Government officials have conceded it could take months to bring the reactors under control.

Fears of contamination have devastated farming and fishing communities in the area. Tepco, however, was unable to say when compensation would be paid, or how much.

The promise of cash was not enough for one protester outside the firm's headquarters in the capital. "I can't work and that means I have no money," Shigeaki Konno, a car mechanic who lived seven miles from the Fukushima plant before he was forced to leave, told Reuters. "The talk about compensation is not concrete. We need it quickly."

Kensuke Takeuchi, a manager at Tepco, said the firm was not yet in a position to compensate residents, adding that he would pass on the protesters' demands to executives.

Despite the magnitude of the accident, and errors in Tepco's initial handling of the crisis, the government appears determined to ensure the firm's survival. **Yomiuri Shimbun newspaper reported that Tepco and the government were considering placing a £15bn to £28bn cap on the company's liabilities to avoid financial ruin in the face of compensation claims that could reach £80bn.**

The [nuclear power](#) company, which has lost three-quarters of its market value since the tsunami on 11 March, is Japan's largest issuer of corporate bonds and its shares are widely held by financial institutions.

The government's chief spokesman, Yukio Edano, said he was not aware of the payout plan. "I have not been notified beyond what has been reported in the media," he said.

On Tuesday the prime minister, Naoto Kan, said Tepco would be responsible for compensating victims but it was the government's job to ensure the payments were made.

Shimizu said he was not aware of the scheme, and refused to discuss calls for his resignation. "My biggest responsibility is to resolve the situation at the Fukushima Daiichi plant, support people who have been evacuated and make sure we provide electricity by overcoming the supply shortage as soon as possible," he said. "I am not in a position to comment on whether or not I will resign."

Under the proposals Tepco would be required to pay 100bn to 200bn yen a year for 15 years. Other utilities would contribute to a 2.7tn yen fund, with the remainder of the compensation coming from the state.

The agony for communities near the plant shows no signs of ending, despite assurances from Kan that the operation to reduce radiation leaks was making progress. Sixteen towns and facilities have been ordered to stop shipping produce, while tsunami damage has destroyed fishing and farming businesses across Japan's north-east coast.

Excessive radioactive cesium found in fish caught off Fukushima

TOKYO, April 13, Kyodo

Radioactive cesium 25 times above the legal limit for consumption was detected Wednesday in young sand lance caught off Fukushima Prefecture, the Ministry of Health, Labor and Welfare said.

One of the sample fish had a level of cesium of 12,500 becquerels per kilogram about 500 meters off the city of Iwaki, and 35 kilometers from the crippled Fukushima Daiichi nuclear power station, it said. The limit is 500 becquerels under the Food Sanitation Law.

TEPCO confirms damage to part of No. 4 unit's spent nuke fuel

TOKYO, April 14, Kyodo

Some of the spent nuclear fuel rods stored in the No. 4 reactor building of the crisis-hit Fukushima Daiichi power plant were confirmed to be damaged, but most of them are believed to be in sound condition, plant operator Tokyo Electric Power Co. said Wednesday.

The firm known as TEPCO said its analysis of a 400-milliliter water sample taken Tuesday from the No. 4 unit's spent nuclear fuel pool revealed the damage to some fuel rods in such a pool for the first time, as it detected higher-than-usual levels of radioactive iodine-131, cesium-134 and cesium-137.

The No. 4 reactor, halted for a regular inspection before last month's earthquake and tsunami disaster, had all of its 1,331 spent fuel rods and 204 unused fuel rods stored in the pool for the maintenance work and the fuel was feared to have sustained damage from overheating.

The cooling period for 548 of the 1,331 rods was shorter than that for others and the volume of decay heat emitted from the fuel in the No. 4 unit pool is larger compared with pools at other reactor buildings.

According to TEPCO, radioactive iodine-131 amounting to 220 becquerels per cubic centimeter, cesium-134 of 88 becquerels and cesium-137 of 93 becquerels were detected in the pool water. Those substances are generated by nuclear fission.

The government's Nuclear and Industrial Safety Agency said the confirmed radioactive materials were up to 100,000 times higher than normal but that the higher readings may have also been caused by the pouring of rainwater containing much radioactivity or particles of radiation-emitting rubble in the pool.

The roof and the upper walls of the No. 4 reactor building have been blown away by a hydrogen explosion and damaged by fires since the disaster struck the plant. The water level in the spent fuel pool is believed to have temporarily dropped.

TEPCO said the fuel rods may have also been damaged by steel frames that fell into the pool in addition to overheating caused by the loss of cooling functions after the twin disasters.

The utility plans to examine the condition of the plant's reactor buildings by deploying a small unmanned helicopter to see whether it is possible to extract spent fuel from pools.

The nuclear agency said now that the condition of the No. 4 unit pool is partially known, workers can better prepare for recovery works there.

Earlier in the day, the government's nuclear regulatory agency ordered TEPCO to check the quake resistance of reactor buildings at the Fukushima plant, which have been rocked by strong aftershocks from the magnitude-9.0 earthquake that wrecked the site and triggered tsunami on March 11.

The agency told the utility to immediately examine the buildings and consider reinforcement work if they are judged as not sufficiently quakeproof.

In addition to the No. 4 unit, the Nos. 1 and 3 reactor buildings have also been severely damaged by hydrogen explosions in the early days of the crisis.

"As strong aftershocks occur almost daily, we have to consider what will happen to buildings already damaged by blasts," said Hidehiko Nishiyama, a spokesman for the nuclear agency.

He acknowledged the difficulties involved in the work to reinforce the quake resistance of the buildings, where radiation levels are high, but said, "We must devise some ways." The agency urged TEPCO to report back to it on the matter as soon as possible.

Meanwhile, Yoko Komiyama, senior vice minister of health, labor and welfare, said Wednesday at a Diet session that a total of 22 workers at the plant have been exposed to radiation exceeding 100 millisieverts as of early Wednesday and that the highest level of exposure among them is 198.24 millisieverts.

Exposure to 100 millisieverts is the permissible level for nuclear plant workers dealing with an emergency, but the limit has been raised to 250 millisieverts for the ongoing crisis.

Workers continued Wednesday to remove highly radioactive water in the plant as part of efforts to put an end to the emergency, which is now acknowledged as one of the world's worst nuclear disasters.

TEPCO had pumped out 700 tons of highly polluted water by Wednesday evening from an underground tunnel-like trench to a "condenser," where in normal operations steam from the reactor is converted into water.

Eventually, the operator plans to remove a total of 60,000 tons of contaminated water, found in the basements of the Nos. 1 to 3 reactor turbine buildings as well as the trenches connected to them, and to store it in nearby tanks and other areas.

As a result of the operation, the level of highly radioactive water that had been filling up the trench connected to the No. 2 reactor's turbine building was lowered. Nishiyama said it will likely take **several weeks before the tainted water removal operation ends.**

The highly toxic water is believed to originate from the No. 2 reactor's core, where fuel rods have partially melted. The water, which has also affected other parts of the plant, is hampering efforts to restore the reactors' key cooling functions, lost in the March 11 earthquake and tsunami.

The nuclear agency also said TEPCO has installed three steel sheets near a seawater intake for the No. 2 reactor and set up "silt fence" curtain barriers near intakes for the Nos. 3-4 reactors at the six-reactor plant to block the spread of radioactive substances in water.

Massive amounts of water have been poured into the reactors and their spent nuclear fuel pools as a stopgap measure to cool them down at the Fukushima plant.

But pools of contaminated water have been detected in various parts of the nuclear complex on the Pacific coast, with some water leaking into the sea, as an apparent side effect of the emergency measure. TEPCO successfully stopped the leak of highly radioactive water from a cracked pit on April 6.

Onagawa nuke plant suffers jolt greater than designed in aftershock

Japan continues to struggle to remove highly toxic water at plant

TOKYO, April 14, Kyodo

The difficult task of removing highly radioactive water at the crisis-hit Fukushima Daiichi nuclear power plant continued Thursday, with **the level of polluted water in the plant's underground trench found to be edging up again that morning after some 660 tons were pumped out.**

The removal of some 60,000 tons of contaminated water from the basements of the Nos. 1 to 3 reactor turbine buildings as well as trenches connected to them is vital, as the water is hampering work to restore key cooling functions of the reactors lost in the March 11 killer earthquake and ensuing tsunami.

Plant operator Tokyo Electric Power Co. pumped out about 660 tons of highly radioactive water Tuesday and Wednesday from one of the trenches to a "condenser" inside the nearby No. 2 reactor turbine building, where in normal operations steam from the reactor is converted into water.

But the Nuclear and Industrial Safety Agency said that the water level at the vertical part of the trench as of 7 a.m. Thursday had increased by about 3.5 centimeters from the level observed at 6 p.m. Wednesday.

The level of the water is 2.5 centimeters lower than just before the water-transferring mission started.

Hidehiko Nishiyama, the agency's spokesman, said that the rise in the water level is likely linked to the continued injection of water into the No. 2 reactor core, which is necessary to prevent the nuclear fuel inside from overheating.

"As there is believed to be around 20,000 tons of water (in the No. 2 reactor turbine building and the trench connected to it), we feel the difficulty of lowering the level of the water in a stable manner," he said.

Tokyo Electric, known as TEPCO, is preparing to transfer more of the highly radioactive water into a facility for nuclear waste disposal in the plant, which can accommodate 30,000 tons of liquid.

The water in and around the No. 2 reactor turbine building is believed to contain higher concentrations of radioactive substances than other contaminated water found at the site, and is believed to originate from the No. 2 reactor's core, where fuel rods have partially melted.

TEPCO also started looking into how to check the quake resistance of already heavily damaged reactor buildings at the site in line with an order issued Wednesday by the government's nuclear regulatory agency, in light of strong aftershocks from the March 11 quake.

The agency has told the utility to immediately examine the buildings and consider reinforcement work if they are judged as not sufficiently quakeproof.

TEPCO, however, has said that it cannot "immediately conduct an investigation" unless it confirms the safety of areas where checkups will be conducted.

To enhance preparation for tsunami waves triggered by aftershocks and other emergency situations, emergency diesel power or vehicle-mounted power sources are to be placed at higher ground, while backup units for water injection to the troubled Nos. 1 to 3 reactors are expected to be installed, according to the nuclear agency.

Academics eye extensive study on impact of nuclear crisis

TOKYO, April 14, Kyodo

Professors and researchers from across Japan will jointly launch a large-scale study on the environmental and health effects of radioactive materials spread by the crisis-hit Fukushima Daiichi nuclear power plant, people familiar with the matter said Thursday.

More than 100 professors and other scholars will take part in collecting data on the impact of Japan's worst-ever nuclear crisis while establishing a team of academics to check the radiation exposure of residents in areas affected by the leak of radioactive substances.

Starting in May, part of the group, working with the Fukushima prefectural government that has already begun its own survey, will collect soil samples at 1,500 locations in areas stretching 100 kilometers along the coastal area centering on the crippled power plant as well as 60 km inland.

With regard to seawater contamination, they will look into the spread of radioactive materials off Fukuoka Prefecture, and their concentration in the food chain and impact on organisms.

They will consider establishing a website to disclose their findings.

The radiation checks will likely cover around 200,000 people living near the Fukushima plant, including around 30,000 who are 14 years old or younger and at high risk of cancer resulting from radioactive iodine accumulation in the thyroid gland.

The main participants in the study will include professors from the University of Tokyo and Osaka University.

U.S. sends water storage tanks, trailer to Fukushima nuclear plant

TOKYO, April 14, Kyodo

The U.S. Department of Energy is shipping five large stainless steel tanks for storing water contaminated with radioactive materials and a tractor trailer with a shielded tank to the crippled Fukushima Daiichi nuclear power plant as part of its assistance, the U.S. Embassy in Tokyo said Thursday.

The **stainless steel tanks** are expected to be used to store contaminated water from the basements of the Nos. 1 to 3 reactor turbine buildings and connecting trenches, while the tractor trailer equipped with the shielded tank will allow for contaminated water characterization.

The pools of highly radioactive water are the major obstacles to work to restore the reactors' cooling functions lost after the March 11 earthquake and tsunami.

Details regarding the size of the tanks and expected arrival date were not immediately known.

Stainless steel ???

Groundwater radiation level at nuke plant rises: TEPCO

TOKYO, April 15, Kyodo

The **concentration levels of radioactive iodine and cesium in groundwater near the troubled Nos. 1 and 2 reactors at the Fukushima Daiichi nuclear power plant have increased up to several dozen times in one week, suggesting that toxic water has seeped from nearby reactor turbine buildings or elsewhere,** Tokyo Electric Power Co. said Thursday.

The announcement came as the plant operator continued to grapple with pools of highly radioactive water found on the plant's premises, with **the level of polluted water filling an underground trench edging up again after the company finished pumping out around 660 tons of water.**

According to the latest findings, a groundwater sample taken April 6 near the No. 1 reactor turbine building showed radioactive iodine-131 of 72 becquerels per cubic meter, with the concentration level growing to 400 becquerels as of Wednesday. The concentration level of cesium-134 increased from 1.4 becquerels to 53 becquerels.

The government's nuclear regulatory agency said it had ordered the utility firm known as TEPCO to enhance monitoring of groundwater inside the plant, which is located on the Pacific coast.

A total of around 60,000 tons of contaminated water is believed to be flooding the basements of the Nos. 1 to 3 reactor turbine buildings as well as trenches connected to them, and the water is hampering work to restore the cooling functions of the reactors lost since the March 11 earthquake and ensuing tsunami.

The pools of contaminated water are believed to be a side effect of TEPCO's emergency efforts to continue injecting water into the reactors and their spent nuclear fuel pools from outside to cool them down.

TEPCO pumped out around 660 tons of highly radioactive water Tuesday and Wednesday from one of the trenches to a "condenser" inside the nearby No. 2 reactor turbine building, where during normal operation steam from the reactor is converted into water.

But the Nuclear and Industrial Safety Agency said the water level in the vertical part of the trench as of 11 a.m. Thursday had increased by about 4.5 centimeters from the level observed at 6 p.m. Wednesday.

The level of the water is now only 1.5 centimeters lower than shortly before the water-transfer mission started at 7:35 p.m. Tuesday.

Hidehiko Nishiyama, the agency's spokesman, told a press conference Thursday morning that the rise in the water level is likely linked to the continued injection of water into the No. 2 reactor core, which is necessary to prevent the nuclear fuel inside from overheating.

"As there is believed to be around 20,000 tons of water (in the No. 2 reactor turbine building and the trench connected to it), we're feeling the difficulty of lowering the level of the water in a stable manner," he said.

TEPCO is preparing to transfer more of the highly radioactive water into a facility for nuclear waste disposal at the plant, which can accommodate 30,000 tons of liquid.

Work is under way to ensure that the facility will be able to contain highly radioactive water safely without fear of the stored liquid leaking outside, but **Nishiyama told the press conference that he was not sure when it would end.**

The water in and around the No. 2 reactor turbine building is believed to contain higher concentrations of radioactive substances than other contaminated water found at the site, and is believed to originate from the No. 2 reactor's core, where fuel rods have partially melted.

The agency decided to remove water from the trench first as it feared that the water inside the trench would overflow and leak into the Pacific Ocean.

TEPCO also started looking into how to check the quake resistance of already heavily damaged reactor buildings at the site in line with an order issued Wednesday by the nuclear regulatory agency, in light of a series of strong aftershocks of the March 11 quake.

The agency has told the utility to immediately examine the buildings and consider reinforcement work if they are judged as not sufficiently quakeproof.

TEPCO, however, has said that it cannot "immediately conduct an investigation" unless it confirms the safety of areas where checks will be conducted.

To enhance preparation for tsunami waves triggered by aftershocks and other emergency situations, emergency diesel power generators and vehicle-mounted power sources are to be placed on higher ground, while backup units for water injection at the troubled Nos. 1 to 3 reactors are expected to be installed, according to the nuclear agency.

Meanwhile, concern grew over the state of the No. 3 reactor at one point, as the agency said in the afternoon that the temperature of part of its reactor pressure vessel was found to be rising suddenly.

??????

But TEPCO officials said the data were likely due to a glitch in a measuring instrument, because other temperature data related to the vessel has not shown a similar rise.

<http://english.kyodonews.jp/news/2011/04/85646.html>

Melted nuclear fuel likely settled at bottom of crippled reactors

TOKYO, April 15, Kyodo

Nuclear fuel inside the crippled reactors at the Fukushima Daiichi power plant has partially melted and settled at the bottom of pressure vessels in the shape of grains, according to an analysis by the Atomic Energy Society of Japan made public by Friday.

The academic body's panel on nuclear energy safety has said the melted fuel at the No. 1 to 3 reactors has been kept at a relatively low temperature, discounting the possibility that a large amount of melted fuel has already built up at the bottom of their reactor vessels given the temperature readings there.

A large buildup of melted nuclear fuel at the bottom could become a molten mass so hot that it could damage the critical containers and eventually leak huge amounts of radioactive material.

The panel has also said that the fuel grains with a diameter of between several millimeters and 1 centimeter are believed to have settled flatly at the bottom of the vessels, leaving almost no possibility of a nuclear chain reaction called "recriticality."

Takashi Sawada, deputy chairman of the group, gave the assessment that even if the current stabilization efforts proceed smoothly, it would take **at least two to three months** for the fuel to be stabilized with few if any radioactive emissions.

The panel also found that the fuel rods in the No. 1 to 3 reactors have been damaged after analyzing information made public by the plant operator Tokyo Electric Power Co. and the Nuclear and Industrial Safety Agency under the Ministry of Economy, Trade and Industry.

The panel has presumed that the fuel has slowly melted and become grain shaped as it was quenched when it fell into the cooling water and then settled down at the bottom of the reactor pressure vessels.

Parts of the fuel rods in the No. 1 and 2 reactors have apparently been exposed, while those in the No. 3 reactor have been completely submerged in water, according to the panel.

Meanwhile, small amounts of plutonium believed to have been released as a result of the ongoing disaster have been detected in soil samples taken at the nuclear complex in Fukushima Prefecture, the plant operator known as TEPCO said.

It is the third time that traces of plutonium have been found in soil samples taken at the plant. The latest samples were taken on March 31 and April 4. The levels of plutonium in them were about the same levels observed in Japan following previous nuclear tests elsewhere, according to the utility.

On Friday, workers continued their efforts to bring the reactors under control and stop radioactive leaks from the seaside plant, injecting more nitrogen gas into the No. 1 reactor and installing more steel sheets near a seawater intake for the No. 2 reactor.

TEPCO said it will throw sandbags containing zeolite, a mineral that absorbs radioactive material, into the sea near the plant to **reduce** the levels of contamination in the seawater.

The nitrogen injection is aimed at preventing a hydrogen explosion at the reactor. At a news conference on Friday, nuclear safety agency spokesman Hidehiko Nishiyama said the agency is also considering injecting nitrogen into the other two troubled reactors soon.

TEPCO has pumped out around 660 tons of highly radioactive water from a tunnel connected to the No. 2 reactor's turbine building into a container inside the building.

The operation resulted in a lower water level in the vertical part of the tunnel, but the agency said that as of Friday morning the level had risen back to the same level as before the water transfer started on Tuesday.

Removing the highly contaminated water that has flooded the basements of the No. 1 to 3 reactor turbine buildings and adjacent tunnels is seen as key to restoring critical cooling systems for the damaged reactors, which were lost in the March 11 earthquake and tsunami.

The flooding water is believed to be an unintended side effect of TEPCO's stopgap measure of injecting water into the reactors and their spent nuclear fuel pools to prevent them from overheating

<http://english.kyodonews.jp/news/2011/04/85725.html>

The agency said, meanwhile, that pressure inside the No. 1 reactor has dropped somewhat, an **indication that air inside the reactor has leaked outside**, but that no major changes in radiation levels have been detected.

....indication that air inside the reactor has leaked outside, but that no major changes in radiation levels have been detected....

OPINION: How to minimize consequences of the Fukushima catastrophe

By Alexey V. Yablokov
MOSCOW, April 15, Kyodo

The analysis of the health impact of radioactive land contamination by the accident at the Fukushima Daiichi nuclear power plant, made by Professor Chris Busby (the European Committee of Radiation Risk) based on official Japanese Ministry of Education, Culture, Sports, Science and Technology data, has shown that over the next 50 years it would be possible to have around 400,000 additional cancer patients within a 200-kilometer radius of the plant.

This number can be lower and can be even higher, depending on strategies to minimize the consequences. Underestimation is more dangerous for the people and for the country than overestimation.

Based on Chernobyl experiences, it is necessary to understand that it may be impossible to quickly get back to life before the catastrophe and to accept the post-Fukushima realities as soon as possible.

The main directions of actions that should be taken:

1. Enlarge the exclusion zone to at least about a 50-km radius of the plant;
2. Distribute detailed instructions on effective ways to protect the health of individuals while avoiding the additional contamination of food. Organize regular measurements of all people by individual dose counters (for overall radionuclides) at least once a week. Distribute the radioprotectors and decontaminants (substances which provide the body protection against harmful effects of radiation) of radionuclides. There are many of such food additives;
3. Develop recommendations for safe agriculture on the contaminated territories: reprocessing of milk, decontamination of meat, turning agriculture into production of technical cultures (e.g. biofuels etc.). Such "radionuclide-resistant" agriculture will be costly (it may be up to 30-40 percent compared with conventional agriculture) and needs to be subsidized;

4. It is necessary to urgently improve existing medical centers -- and possibly create new ones -- to deal with the immediate and long-term consequences of the irradiated peoples (including medical-genetic consultations on the basis of chromosome analysis etc.);

5. The most effective way to help organize post-Fukushima life in the contaminated territories (from Chernobyl lessons) is to create a special powerful interagency state body (ministry or committee) to handle the problems of contaminated territories during the first most complicated years.

I am sure that Russian, Belarusian and Ukrainian radiation medicine and agriculture specialists, radiobiologists and radioecologists who have enormous experience in fighting radiation consequences will be ready to cooperate with Japan.

(Alexey V. Yablokov is a councilor for the Russian Academy of Science and a principal author of "Chernobyl: Consequences of the Catastrophe for People and the Environment," published in 20

Fukushima seawater radioactivity rises inside containment fence

TOKYO, April 16, Kyodo

The level of radioactive substances in seawater increased sharply overnight inside a containment fence installed near the Fukushima Daiichi nuclear power plant, the operator Tokyo Electric Power Co. said Saturday.

The utility said the rise suggested that the fence is helping to curb the spread of contaminated water, but the government's Nuclear Industrial and Safety Agency remained cautious, citing the possibility that radioactive water could still be seeping from the complex.

The company said the level of radioactive iodine rose Saturday morning to 260 becquerels per cubic centimeter in seawater inside the fence near an intake leading to the No. 2 reactor.

The figure, 6,500 times the legal limit, was around six times the 42 becquerels detected the previous day, the company said, adding the reading of radioactive cesium had also jumped by four times.

TEPCO also said it plans on Sunday or later to throw sandbags containing zeolite, a mineral that absorbs radioactive materials, into the sea near intakes leading to the Nos. 1, 2 and 3 reactors to reduce the levels of contamination.

Meanwhile, the utility is considering installing circulating water cooling systems for reactors and spent fuel storage pools outside the reactor buildings at the plant in a bid to bring it under control, sources familiar with the matter said.

The new systems would cool nuclear fuel inside the reactors and spent fuel pools in a stable manner. They would involve heat exchangers and circulation pumps to drain reactor coolant water from the containment buildings, cooling it with seawater and then sending it back to the reactors, the sources said.

TEPCO appears to have already placed orders for dozens of gasketed plate heat exchangers -- each measuring 3 meters high, 1 meter wide and 2 meters long -- for such systems, the sources said.

The existing circulating water cooling systems at the plant were crippled by the March 11 earthquake and ensuing tsunami.

The utility has been pumping water into reactors and storage pools in a desperate bid to cool them. But the move has created large puddles of water contaminated with high levels of radiation inside the reactor containment and turbine buildings, as fuel rods in the reactors and storage pools have been partially damaged.

The presence of the large puddles in the buildings has blocked restoration work at the plant.

TEPCO has therefore determined that it is necessary to cool the reactors and storage pools with new circulating water cooling systems to be installed outside the containment buildings, they said.

It is impossible to sufficiently cool the reactors and storage pools simply by pumping water into them without circulating water through the reactors and pools. The pumping operation has also had the negative side effect of raising the water levels of the radiation-contaminated puddles.

It would be necessary to secure five or six heat exchangers to cool one reactor, but the cooling efficiency of the gasketed plate heat exchangers is twice that of conventional heat exchangers for nuclear plants, according to the sources.

Radiation levels inside the containment buildings remain high. TEPCO plans to utilize the pipes that it has been using to pump water into the reactors in the new circulating water cooling loops, so it can minimize the need for work inside the dangerous buildings.

Japan nuclear commission fails to send experts to Fukushima

TOKYO, April 16, Kyodo

The Nuclear Safety Commission of Japan has failed to send designated experts to Fukushima Prefecture to look into the crisis at the crippled Fukushima Daiichi nuclear power plant even though a national disaster-preparedness plan requires it to do so, many of the experts said Saturday.

A commission spokesperson said problems following the March 11 earthquake and tsunami such as blackouts had discouraged it from sending any experts to Fukushima Prefecture, but many of the specialists and government officials questioned the claim.

The commission designates 40 nuclear accident experts including university professors and senior officials of relevant institutions as well as five others as members of its panel on emergency technical advice.

The disaster plan requires the commission to dispatch members of the panel to a location near an accident site.

The commission has dispatched members of its secretariat to the prefecture since the crisis began the nuclear complex but a government official said, "It seems a problem that none of the designated experts has gone to Fukushima. The matter should be examined in the course of post-accident fact-finding."

Accumulated radiation tops 17,000 microsieverts in Fukushima's Namie

TOKYO, April 16, Kyodo

The accumulated radiation level in Namie, 30 kilometers from the crippled Fukushima Daiichi nuclear power plant, in the three weeks through Friday stood at 17,010 microsieverts, according to a tally released by the science ministry Saturday.

The accumulated levels during the period starting March 23 stood at 9,850 microsieverts in Iitate and 495 microsieverts in Minamisoma, both near the plant, it said. The readings compare with the level of 1,000 microsieverts that ordinary people in Japan can expect to be exposed to over one year.

The amount of radioactive cesium stood between 12.7 and 71.0 becquerels per liter of surface seawater near the plant on Monday and Wednesday and 10.1 becquerels at deeper levels on Monday, the Ministry of Education, Culture, Sports, Science and Technology said.

[Does this mean the level of radiation in these places has only been checked from March 23 ?] and so doesn't include the amounts people received over the first 12 days ?????

TEPCO aims to achieve 'cold shutdown' for reactors in 6-9 months

TOKYO, April 17, Kyodo

Tokyo Electric Power Co. said Sunday that it aims to bring the damaged reactors at the Fukushima Daiichi nuclear power plant to a stable condition known as a "cold shutdown" in about six to nine months, while restoring stable cooling to the reactors and spent fuel pools in about three months.

At a news conference in Tokyo, company Chairman Tsunehisa Katsumata announced the utility's schedule "for the moment" for bringing the complex in Fukushima Prefecture under control, while offering an apology for the ongoing nuclear crisis.

The utility, known as TEPCO, also said it needs three months to achieve "steady reduction" in radiation, and an additional three to six months to control radioactive emissions and curb radiation substantially.

It said it is addressing the immediate challenges of preventing hydrogen explosions at the Nos. 1 to 3 reactors and emission of water contaminated with high-level radiation from the No. 2 reactor.

It also said it will put special covers on the heavily damaged buildings of the Nos. 1, 3 and 4 reactors.

"We will do our utmost to curb the release of radioactive materials by achieving a stable cooling state at the reactors and spent fuel pools," Katsumata said.

He also said he will mull resigning to take responsibility for the nuclear disaster.

At a separate press conference, industry minister Banri Kaieda urged TEPCO to follow the restoration roadmap swiftly and steadily.

The nuclear plant has been crippled by the devastating March 11 earthquake and subsequent tsunami, with the resulting damage causing radioactive materials to be emitted into the environment and forcing residents near the plant to be evacuated.

The government's Nuclear and Industry Safety Agency raised the severity level of the crisis from level 5 to the maximum level 7 on an international scale, recognizing that it matches the world's worst nuclear catastrophe in 1986 at Chernobyl.

chronology events Fukushima

Elevated levels of radiation measured inside reactor buildings

TOKYO, April 18, Kyodo

Elevated levels of radiation have been measured inside the buildings housing the Nos. 1 and 3 reactors at the troubled Fukushima Daiichi nuclear power plant, the nuclear safety agency said Monday.

The Nuclear and Industrial Safety Agency suggested that the readings -- measured at between 10 and 49 millisieverts per hour for the No. 1 unit and between 28 and 57 millisieverts per hour for the No. 3 unit -- put time constraints on any work that must be done inside the reactors.

On Sunday, two remotely controlled robots measured radiation levels and other parameters inside the buildings. The plant operator, Tokyo Electric Power Co., has found it **difficult to send workers inside them due to concerns that they may be exposed to high levels of radiation.**

Up to 57 millisieverts measured at Nos. 1, 3 reactor buildings

TOKYO, April 18, Kyodo

The radiation level inside the troubled Nos. 1 and 3 reactor buildings at the Fukushima Daiichi nuclear power plant was up to about 57 millisieverts per hour as of Sunday, data obtained by remote-controlled robots showed Monday.

19h24 : reactor n° 4 building flooded with water 5 metres high

Gov't panel releases 2 of over 2,000 radiation dispersal estimates

TOKYO, April 18, Kyodo

The Nuclear Safety Commission of Japan has released only two computer-simulated estimates of radioactive substance dispersal since the nuclear accident at the Fukushima Daiichi power plant, although more than 2,000 of them were made, sources familiar with the matter said Monday.

The estimates were made using the Nuclear Safety Technology Center's networked computer system known as SPEEDI, or system for prediction of environmental emergency dose information, developed and operated with a budget of about 12.8 billion yen.

The government commission released the two estimates on March 23 and April 11, including accumulated exposure to a radiation dose of more than 1 millisievert even outside a radius of 30 kilometers from the Fukushima plant that was crippled by the March 11 earthquake and tsunami.

Radiation inside Nos. 1, 3 reactor buildings up to 57 millisieverts

TOKYO, April 18, Kyodo

The radiation level inside the Nos. 1 and 3 reactor buildings at the crippled Fukushima Daiichi nuclear power plant was up to about 57 millisieverts per hour as of Sunday, the government's nuclear safety

agency said Monday, acknowledging that it is **a level that puts time constraints on any restoration work that must be done there.**

The Nuclear and Industrial Safety Agency also said that it has found the No. 4 reactor building flooded with water 5 meters high, besides some 60,000 tons of contaminated water already found to be filling up the Nos. 1 to 3 reactor turbine buildings and nearby areas.

Many of the pools of water containing radioactive substances are believed to be a side effect of an emergency measure of pouring massive amounts of water into the reactors and their spent nuclear fuel pools from outside to keep them cool, given that they have lost their key cooling functions following the March 11 earthquake and tsunami.

<http://www.spiegel.de/wissenschaft/technik/0,1518,757732,00.html>

...

Die Hightech-Roboter werden von der Firma iRobot aus Bedford im US-Bundesstaat Massachusetts hergestellt. Der Raupenantrieb macht sie manövrierfähig, dazu können die Maschinen Türen öffnen und kleinere Trümmerteile aus dem Weg räumen. Die Aufnahmen des Roboters aus dem Reaktorgebäude 3 zeigten Berge von Schutt - auch für den Roboter sei ein Vorankommen schwierig gewesen, hieß es. In Reaktor 1 sei der PackBot in den Eingangsbereich vorgedrungen.

Die gemessene Radioaktivität betrug 10 bis 49 Millisievert pro Stunde in Block 1 und 28 bis 57 Millisievert pro Stunde in Block 3. Das ist nach Angaben des Betreibers Tepco **fast 6000-mal höher als im Normalbetrieb des Reaktors. Ab einem Wert von 1000 Millisievert bestehe akute Gesundheitsgefahr durch Strahlenkrankheit, die Übelkeit und Erbrechen zur Folge hat.**

Es ist nicht das erste Mal, dass der PackBot bei international beachteten Rettungseinsätzen verwendet wird. Eine frühe Version des High-Tech-Apparats wurde in den Trümmern des World Trade Centers nach den Anschlägen vom 11. September 2001 eingesetzt.

Greenpeace Messungen

.. Die Region um die Atomruine Fukushima ist nach Messungen der Umweltorganisation Greenpeace spürbar radioaktiv belastet. In der Stadt Fukushima, rund 60 Kilometer vom Atomkraftwerk entfernt, seien noch bis zu vier Mikrosievert pro Stunde gemessen worden, sagte Greenpeace-Experte Thomas Breuer nach einer Messkampagne am Montag in Hamburg. Ein Mikrosievert entspricht einem Tausendstel Millisievert.

Die Bevölkerung bekomme dort in 14 Tagen die höchste vertretbare künstliche Strahlendosis für ein Jahr ab. In zwei Dörfern der Region seien Werte von 7 bis 48 Mikrosievert pro Stunde gemessen worden, **dort erhielten die Bewohner bereits in zwei Tagen die Jahresdosis.**

COMMUNIQUE CRIIRAD

du 17 mars 2011 - 13h

RADIOACTIVITE DE L'AIR :

Les quelques résultats enfin disponibles sont très inquiétants !

Des résultats nous parviennent d'heure en heure et confirment les éléments ci-dessous.

Nous essaierons de publier une mise à jour en fin de journée

Suivre en temps réel l'ordre de grandeur de la contamination de l'air est indispensable

Depuis 5 jours, de la radioactivité s'échappe de la centrale nucléaire de FUKUSHIMA DAIICHI sans que l'on puisse évaluer les risques encourus par les populations. On n'a en effet aucune idée des quantités de produits radioactifs relâchées dans l'environnement et aucune cartographie des activités volumiques de l'air n'a été publiée.

Seuls des relevés dosimétriques (débits de dose en $\mu\text{Gy/h}$ ou $\mu\text{Sv/h}$) sont disponibles et seulement pour certains secteurs géographiques. Les plus exposés – la Préfecture de Fukushima notamment – sont très peu documentés [la situation est en train de changer]. Ces résultats ne rendent compte que de l'exposition externe et peuvent donc sous-évaluer considérablement les niveaux de risques.

En situation accidentelle, il est indispensable de disposer, en temps réel, des ordres de grandeurs de la contamination de l'air qui 1/ détermine le risque encouru par inhalation de gaz et d'aérosols radioactifs ; 2/ conditionne – en association avec les paramètres météorologiques - l'intensité des dépôts au sol et par conséquent les niveaux de contamination de la chaîne alimentaire.

Tout un cocktail de produits radioactifs dans l'air de Tokyo

Le laboratoire de la CRIIRAD a pu accéder aux mesures effectuées par le [Tokyo Metropolitan Industrial Technology Research Institute](#) sur les poussières atmosphériques prélevées à Tokyo, dans l'arrondissement de Setagaya, sur la période du mardi 15 mars minuit au mercredi 16 mars 18h (heures locales), soit 42 heures de suivi.

Les résultats publiés concernent 4 radionucléides (produits radioactifs) : iode 131, iode 132, césium 134 et césium 137. Moyennées sur les 42 heures de suivi, les activités sont les suivantes :

- Iode 131 : 14,9 Bq/m³
- Iode 132 : 14,5 Bq/m³
- Césium 134 : 3,4 Bq/m³
- Césium 137 : 3,2 Bq/m³

Accéder aux tableaux de résultats : 1. [Mise en forme CRIIRAD](#)

2. [Originaux de l'Institut de Recherche de Tokyo : 15-03-11 ; 16-03-11 ; 17-03-11](#)

En situation normale, le seul radionucléide que l'on s'attend à mesurer dans l'atmosphère est le césium 137. Du fait des essais nucléaires militaires et de la catastrophe de Tchernobyl, subsiste en effet une contamination résiduelle mais heureusement très faible : de l'ordre de quelques $\mu\text{Bq}/\text{m}^3$. ($1\mu\text{Bq} = 10^{-6}\text{Bq}$) Une valeur moyenne de 3,4 Bq/m³ représente une augmentation considérable du niveau de radioactivité : de l'ordre de 1 million de fois.

Précision importante : l'air contient nécessairement d'autres radionucléides : probablement des gaz rares radioactifs comme le krypton 85 et le xénon 133 mais également du tritium, du tellure 132, des isotopes du ruthénium, du tellure, du strontium. Il faudrait également savoir si l'air contient des transuraniens, des émetteurs alpha très radiotoxiques comme les plutoniums 238, 239 ou 240 ou encore l'américium 241.

Si l'on considère l'évolution des concentrations dans le temps, on constate que le niveau de radioactivité de l'air a très fortement augmenté sur Tokyo le 15 mars, entre 10h et 12h, avec un pic de radioactivité sur les poussières prélevées à 11h :

- Iode 131 : 241 Bq/m³
- Iode 132 : 281 Bq/m³
- Césium 134 : 64 Bq/m³
- Césium 137 : 60 Bq/m³ (soit plus de 10 millions de fois le niveau antérieur aux accidents nucléaires)

[Accéder au graphique établi par la CRIIRAD \(résultats actualisés au 17 mars\)](#)

A partir d'une activité moyenne en iode 131 de 15 Bq/m³, nous avons calculé les doses équivalentes à la

thyroïde qu'ont pu recevoir en 48 heures les enfants habitant Tokyo. Les résultats restent inférieurs au milliSievert (mSv) et par conséquent au seuil d'intervention de 10 mSv défini par l'OMS pour l'administration de comprimés d'iode stable.

Il faut cependant souligner que les chiffres utilisés pour les calculs sous-évaluent très probablement l'activité réelle de l'air. L'air a, en effet, été échantillonné à partir de filtres à poussières. Pour obtenir un bilan complet, il faudrait disposer de résultats sur des filtres à charbon actif capables de piéger les gaz, et notamment les formes moléculaires et organiques de l'iode. Elles peuvent représenter une part importante, voire majoritaire, de l'iode présent. Cette information doit être obtenue d'urgence.

Que se passe-t-il plus au nord ?

Le plus préoccupant est que Tokyo n'est pas le secteur le plus touché par le passage des masses d'air contaminé. L'analyse des relevés de débits de dose disponibles le montre clairement. Ces quelques éléments très – trop – lacunaires nous conduisent à nous interroger sur les niveaux d'exposition des personnes résidant à moindre distance de la centrale de FUKUSHIMA DAIICHI (Tokyo est situé à 230 km au sud). A quels niveaux de contamination ont été exposés les habitants de la Préfecture de Fukushima (l'évacuation est limitée à un rayon de 20 km) ou encore ceux du secteur d'ONAGAWA où les débits de dose ont été multipliés par 100, voire par 1 000 (à Tokyo, l'augmentation n'aurait été que d'un facteur 16) ? Et qu'en est-il des habitants de la Préfecture d'IBARAKI où l'élévation du niveau de rayonnement ambiant est un peu supérieure à celle de Tokyo et surtout bien plus prolongée ?

La CRIIRAD ne souhaite qu'une chose, c'est d'être rassurée sur les niveaux d'exposition de la population. Si les autorités considèrent que les niveaux de risques sont minimes, elles doivent le démontrer, chiffres à l'appui.

Si l'on se base sur les informations publiées par l'AIEA, jusqu'au mercredi 16 mars, l'ordre d'administrer des comprimés d'iode stable à la population n'avait pas été donné. L'AIEA indique que dès le 14 mars dernier, les autorités japonaises avaient distribué 230 000 tablettes de comprimés d'iode stable aux centres d'évacuation mais sans donner l'ordre de les administrer aux habitants. Or, la zone d'évacuation était encore hier limitée à un rayon de 20 km autour de FUKUSHIMA DAIICHI et consigne était donnée aux

personnes résidant dans un rayon de 30 km de se confiner chez elles.

Le problème, c'est que le confinement ne peut apporter qu'une protection très provisoire : une habitation n'a rien d'une enceinte étanche : en quelques heures tout le volume d'air intérieur est renouvelé. On gagne un peu de temps en calfeutrant toutes les ouvertures mais le confinement n'est absolument pas adapté à une contamination qui persiste sur plusieurs jours. L'aide internationale doit se mobiliser pour apporter la logistique nécessaire à l'évacuation des personnes sur un périmètre bien plus large. Ceci aurait dû être fait bien plus tôt. En attendant, il faut limiter les risques et l'iode stable est un moyen efficace – s'il est pris à temps ! – de limiter l'irradiation de la glande thyroïde et donc la survenue ultérieure de cancers ou d'autres pathologies thyroïdiennes. Rappelons également que l'iode stable n'est pas la panacée : il ne protège ni de l'irradiation externe, ni de la contamination par les autres radionucléides.

Dépôts au sol et contamination des aliments

La radioactivité présente dans l'air se dépose progressivement au sol et sur les végétaux. Les dépôts secs sont intensifiés par la pluie qui lessive les masses d'air contaminé et précipite au sol les particules radioactives (aérosols) et les gaz solubles (iode notamment).

Il faut disposer au plus vite d'une cartographie des activités surfaciques (Bq/m² de sol) permettant de recenser les zones à risque et de cibler les mesures à prendre pour le retrait des aliments contaminés ou les mesures de prévention (alimentation du bétail en fourrage non contaminé par exemple).

Concernant la contamination de la chaîne alimentaire, il faut rappeler que depuis 5 jours, des quantités très importantes de produits radioactifs sont rejetées à la mer. Il faut donc vérifier l'impact de ces rejets sur les produits de la mer dans les zones proches et en fonction des courants.

Le fait de connaître les niveaux de contamination des paramètres clefs de l'environnement n'est certes pas une garantie de protection. Il est en revanche certain que l'absence de données ne peut qu'empirer les choses. L'opacité n'a jamais profité à la défense des intérêts sanitaires de la population. Tchernobyl l'a clairement démontré.

REPERES

CONTAMINATION DE L'AIR :

comparaison avec la situation de la France au moment de Tchernobyl

Les chiffres qui suivent sont des chiffres officiels relatifs à la contamination de l'air dans le sud-est de la France, une des régions les plus touchées par les retombées radioactives consécutives à l'explosion du réacteur n°4 de Tchernobyl. Les activités sont des valeurs moyennes pour la période du 1^{er} au 3 mai 1986.

Césium 137 : de **0,3 à 0,9 Bq/m³** à comparer à la concentration moyenne sur 2 jours de **3,2 Bq/m³** à Tokyo

Iode 131 : de **0,6 et 4,2 Bq/m³** à comparer à la concentration moyenne sur 2 jours de **14,9 Bq/m³** à Tokyo.

CRIIRAD

Tokyo Electric admits fuel could be melting at Fukushima nuke plant

TOKYO, April 21, Kyodo

An official at Tokyo Electric Power Co., the operator of the crippled Fukushima Daiichi nuclear power plant, admitted Wednesday that fuel of the plant's No. 1 reactor could be melting.

Radioactive leaks into sea were 20,000 times above limit: TEPCO

TOKYO, April 21, Kyodo

Tokyo Electric Power Co. said Thursday radioactive substances that leaked into the sea from its crisis-hit nuclear plant over six days from April 1 totaled an estimated 5,000 terabecquerels, 20,000 times more than the annual allowable limit for the plant.

The radioactive substances were in an estimated 520 tons of high-level radioactive water that leaked into the sea from the No. 2 reactor of the six-reactor Fukushima Daiichi nuclear plant, which was devastated by the March 11 earthquake-tsunami disaster in northeastern Japan. The leaks were found on April 2 and stopped on April 6.

The estimated 5,000 terabecquerels is far lower than 370,000 to 630,000 terabecquerels, the estimated amount of radioactive substances released into the atmosphere from the plant. But it is 30,000 times more than the radioactive substances in low-level radioactive water that TEPCO discharged to secure a storage space for the high-level radioactive water.

Radiation over 100 microsieverts detected 2-3 km from troubled plant

TOKYO, April 21, Kyodo

Radiation levels of over 100 microsieverts per hour were measured at four locations 2 to 3 kilometers from the crippled Fukushima Daiichi nuclear plant from late last month, the science ministry said Thursday as it released such data for the first time.

Reactors, residents and risk

A world population analysis reveals the locations that could put the most people in danger should a nuclear accident occur.

[Declan Butler](#)

Map showing the population size living within 75 kilometres of each of the world's nuclear power plants. Population increases with circle size and with colour, from green (< 0.5 million) to red (> 20 million). You need to download the [Google Earth plug-in](#) to view this graphic. For a larger version, [click here](#).

In the aftermath of the Fukushima nuclear accident, people everywhere are asking: could a similar disaster strike closer to home?

For much of the world's population, distance offers no comfort. An analysis carried out by Nature and Columbia University, New York, shows that two-thirds of the world's 211 power plants have more people living within a 30-kilometre radius than the 172,000 people living within 30 kilometres of the Fukushima Daiichi plant, who have been forced or advised to leave. Some 21 plants have populations larger than 1 million within that radius, and six have populations larger than 3 million.

[Online collection](#)

Population size was just one of the factors that Nature set out to explore in a bid to map reactor hazards around the world. Nuclear experts say that an objective 'danger' ranking is almost impossible because each reactor has its own unique risk profile, and some risks are simply unknowable. Reactor safety depends above all on a 'culture of security', including the quality of maintenance and training, the competence of the operator and the workforce, and the rigour of regulatory oversight, says Mycle Schneider, an independent nuclear consultant based in Paris. This means that a better-designed, newer reactor is not always a safer one. "What is more dangerous, a drunk driver in a brand new Ferrari or a sober Formula 1 pilot in a 30-year-old 2CV?" Schneider says. But experts do agree on a few critical risk factors, and on measures that could limit them.

Population

Population density is one critical lens through which other risks have to be assessed, says Laurent Stricker, a nuclear engineer who is chairman of the World Association of Nuclear Operators (WANO), created as an international forum on nuclear safety in the aftermath of the 1986 Chernobyl accident. "We need to look at the safety of reactors taking into account where they are," he says (see [Nature 472, 274; 2011](#)).

To carry out the population analysis, Nature teamed up with the NASA Socioeconomic Data and Applications Center based at Columbia University (see ['How population sizes were estimated'](#) for an explanation of how the analysis was carried out). The KANUPP plant in Karachi, Pakistan, has the most people — 8.2 million — living within 30 kilometres, although it has just one relatively small reactor with an output of 125 megawatts (see ['Nuclear neighbours'](#)). Next in the league, however, are much larger plants — Taiwan's 1,933-megawatt Kuosheng plant with 5.5 million people within a 30-kilometre radius and the 1,208-megawatt Chin Shan plant with 4.7 million; both zones include the capital city of Taipei. The findings of Nature's population analysis are "scary", says Ed Lyman, a nuclear expert with the Union of Concerned Scientists in Washington DC.

If the radius is broadened to 75 kilometres, the picture looks even more disconcerting. China's neighbouring Guangdong and Lingao plants top that league, each with around 28 million people within a 75-kilometre radius that covers Hong Kong, followed by the Indian Point plant near New York, with 17.3 million, and the Narora plant in Uttar Pradesh, India with 16 million. One hundred and fifty-two nuclear power plants have more than 1 million people living within 75 kilometres; and all but five plants have more than 1 million people within 150 kilometres. Fortunately, prevailing winds have so far blown most of Fukushima Daiichi's radioactivity out to sea, as some 7.7 million people, including some in the greater Tokyo area, live within 150 kilometres of that site (see ['Where the worst could happen'](#)).

External threats

As Fukushima showed, external threats — such as earthquakes, tsunamis, fires, flooding, tornadoes or even terrorist attacks — are some of the greatest risk factors for a serious nuclear accident. Conventionally, nuclear plant operators have considered some accident sequences so unlikely that they have not built in complete safeguards — such accidents are called 'beyond design basis' events. Yet forecasting the location of the next earthquake or the size of the next tsunami is an imperfect art.

This means that nuclear plants situated outside known geological danger zones could pose greater accident threats in the event of an earthquake than those inside, as the former could have weaker protection built in. The Fukushima Daiichi plant, for example, was located in an area designated, on Japan's seismic risk map, as having a relatively low chance of a large earthquake and tsunami; when the 2011 tsunami arrived, it was in excess of anything its engineers had planned for.

The possibility of beyond design basis accidents is a major thrust of the many safety reviews being conducted post-Fukushima. The International Atomic Energy Agency (IAEA) is already paying attention to external threats — creating an internal International Seismic Safety Centre in 2008, for example, after an earthquake hit the Kashiwazaki-Kariwa plant on the west coast of Japan in 2007,

prompting an automatic shutdown and a minor release of radioactivity (see [Nature 448, 392–393; 2007](#)).

Design and age

Some reactors and plants are inherently more dangerous than others. One factor is sheer size. A larger plant can generate more fallout, and when simultaneous crises develop at multiple reactors — as happened at four of Fukushima's six reactors — operators can be overwhelmed. The Kashiwazaki-Kariwa plant has seven reactors, making it the world's biggest in terms of electrical output at 7,965 megawatts. Other such mega-sites, besides Fukushima itself, include Qinshan on China's northeast coast, Yeonggwang and Ulchin in South Korea, the Leningrad plant in Russia, Bruce on the shores of Lake Huron in Ontario, Canada, and Gravelines and Paluel, both on the northern coast of France.

“One hundred and fifty-two nuclear power plants have more than 1 million people living within 75 kilometres.”

Older reactors are not necessarily more dangerous than newer ones. The 1978 Three Mile Island accident in the United States occurred in a reactor that had started operation only three months earlier, and the accident at Chernobyl (now in Ukraine) occurred after only two years of operation. A serious loss of coolant occurred at the French Civaux-1 reactor in 1998, less than five months after start-up. That's not surprising, says Lyman, as reactors follow a well-known trajectory in reliability engineering called the 'bathtub curve'. Complex new machines and installations often have features that haven't been fully tested, or are new to operators, so bugs and mistakes can occur at the start. After the bugs get worked out, reactors enter a relatively lower-risk stable phase, but risk later increases with age-related deterioration. "Institutional loss of memory" is another problem that increases with reactor age, says Jan Beránek, head of nuclear campaigns at Greenpeace International, headquartered in Amsterdam, the Netherlands. "Many engineers who are familiar with the design and were involved in the planning and building of those reactors are retired, and part of their very specific expertise is getting lost."

As the 1986 Chernobyl accident showed, the design itself can pose risks. The Chernobyl reactor core contained flammable graphite, and the fire that burned for weeks after the accident spewed radioactivity high into the atmosphere. The reactor design also contained an inherent instability such that the chain reactions accelerated as the core lost water — an impossible event with most other reactor designs. Several Chernobyl-design reactors are still in operation in Russia, in particular at the plant near St Petersburg, close to large population centres. These reactors have, however, been radically overhauled to address these and other safety issues with the design.

But Lyman cautions against placing too much stock in one reactor design being safer than another. Modern pressurized water reactors would face much the same difficulties as Fukushima if their cooling systems were disabled, he says.

Culture

However safe a plant is designed to be, it is operated by error-prone humans. Operators must guard against complacency, says Stricker. "One flaw that I worry about is that of overconfidence." Experts

say that the largest single internal factor determining the safety of a plant is the culture of security among regulators, operators and the workforce — and creating such a culture is not easy. "It is expensive. And it involves an attention to detail and a willingness to accept and learn from intrusive peer review by others," wrote Richard Meserve, president of the Carnegie Institution for Science in Washington DC, in 2010 as chair of the IAEA's International Nuclear Safety Advisory Group.

Meserve was referring in particular to what many experts see as potentially the fastest-growing risk in the nuclear industry: that many countries with little or no past experience are embarking on nuclear power or are already building large numbers of reactors. Meserve points, for example, to plans to introduce nuclear power in Belarus, Chile, Egypt, Indonesia, Jordan, Lithuania, Malaysia and Morocco, among others. Experts worry about lack of regulatory oversight and corruption in some regions. Stricker says that peer review of plants before they start up will be of particular importance in inexperienced countries, and that WANO intends to increase such reviews.

Tom Cochran, a nuclear expert at the Natural Resources Defense Council in Washington DC, is sceptical that the many post-Fukushima safety reviews already under way in the United States, the European Union and elsewhere will result in significant changes in risk assessment of nuclear reactors. "They will make recommendations and adjustments, but I don't think you can ask regulators to review whether they have made mistakes in the past; I don't think they will do enough." Cochran wants independent commissions to be established, similar to the Kemeny Commission set up to draw lessons from the Three Mile Island accident.

And with risk assessment so difficult, experts say that one of those lessons is that operators must simply prepare better for a serious nuclear emergency. "One change that WANO could, and in my opinion must, make," says Stricker, "is to be in a position to verify that every nuclear operator company from the smallest to the largest has plans to cope with unforeseen accidents."

Workers locked in battle at nuclear plant; exposure to radiation rising

Sunday 24th April, 06:20 AM JST

FUKUSHIMA —

Workers at a nuclear power plant damaged by last month's earthquake and tsunami that devastated Japan's northeast continued battling to deal with radioactive water Saturday as their exposure to radiation is constantly increasing.

One more worker is found to have been exposed to radiation of more than 100 millisieverts, bringing to 30 the total number of people of that dosage level while dealing with the crisis at the Fukushima Daiichi plant since the March 11 disasters, sources familiar with the situation said.

Plant operator Tokyo Electric Power Co said Saturday that a piece of concrete rubble with a high radiation emission of 900 millisieverts per hour was found near the plant's No. 3 reactor and a worker removed it using heavy equipment.

The worker who operated the equipment was exposed to 3.17 millisieverts of radiation, but officials of TEPCO said the dosage does not pose a major problem.

The concrete piece, about 30 centimeters in both length and width with a thickness of about 5 cm, was found Wednesday and removed the following day and is currently being kept inside a container with other pieces of rubble, the officials said.

While workers are removing rubble from the damaged plant using remote-controlled heavy machinery, the one emitting high radiation was removed directly using the equipment so as not to damage an important pipe located nearby, they said.

TEPCO says workers and engineers exposed to radiation close to 200 millisieverts are switched to jobs that risk receiving lower levels of contamination.

Such a policy has been applied to just one worker so far, after his reading rose to 198 millisieverts, according to the utility.

To cope with the Fukushima crisis, the government has raised the legal limit on the amount of radiation to which each worker could be exposed in an emergency situation to 250 millisieverts from 100 millisieverts.

On Saturday, highly toxic radioactive water from the No. 2 reactor was transferred from the basement of a building to a nearby waste-disposing facility for a fifth consecutive day, while attempts were made to prevent it from leaking into the sea.

An estimated 25,000 tons of contaminated water need to be removed, of which 10,000 tons are planned to be sent to the facility by mid-May. Only less than 10% has been transferred so far in a process considered crucial for the plant to restore the cooling functions for its reactors.

At the No. 4 reactor building, the temperature of the spent nuclear fuel pool dropped from 83 C to 66 C after a four-hour process of injecting 140 tons of fresh water using a concrete pump truck, increasing the water level in the pool by 1 meter, TEPCO officials said.

Separately, the science ministry said the cumulative dosage of radiation has exceeded the annual limit set by the government for evacuation at one location in the town of Namie, Fukushima Prefecture, about 30 km northwest of the nuclear complex.

The Ministry of Education, Culture, Sports, Science and Technology said the radiation amount, measured over one month between March 23 and Friday, surpassed the 20-millisievert limit at the place although the pace of accumulation has gradually slowed.

The ministry's data showed the radiation level there reached 10 millisieverts after the first 12 days since the start of measurement, but it took 19 days for an additional 10 millisieverts of radiation to be detected.

Gov't endorses TEPCO's estimates on radioactive leak into sea

TOKYO, April 25, Kyodo

The government's nuclear safety agency on Monday endorsed a report by Tokyo Electric Power Co. estimating radioactive substances 20,000 times the allowable annual limit were carried into the Pacific Ocean by contaminated water leaking from the crisis-hit Fukushima Daiichi nuclear plant in early April.

The Nuclear and Industrial Safety Agency approved the report submitted by the plant operator last Thursday and said the leak would not cause immediate health hazards because radioactive materials would be diluted in seawater, while fishing had been banned in areas close to the atomic power station.

Hidehiko Nishiyama, a spokesman for the nuclear agency, said the concentration of radioactive substances believed to have leaked into the sea from a cracked pit between April 1 and 6 was about 30,000 times higher than the level seen in low-level radioactive water TEPCO deliberately dumped into the sea between April 4 and 10.

OPINION: Children of Fukushima need our protection

By Tilman Ruff

MELBOURNE, April 26, Kyodo

I was dismayed to learn that the Ministry of Education, Culture, Sports, Science and Technology earlier this week increased the allowable dose of ionizing radiation for children in Fukushima Prefecture.

The dose they set, 3.8 microsieverts per hour, equates to more than 33 millisieverts (mSv) over a year. This is to apply to children in kindergartens, nursery, primary and junior high schools. Let me try to put this in perspective.

Widely accepted science tells us that the health risk from radiation is proportional to the dose -- the bigger the dose the greater the risk, and there is no level without risk.

The International Commission on Radiological Protection recommends that all radiation exposure be kept as low as achievable, and for the public, on top of background radiation and any medical procedures, should not exceed 1 mSv per year.

For nuclear industry workers, they recommend a maximum permissible annual dose of 20 mSv averaged over five years, with no more than 50 mSv in any one year.

In Japan the maximum allowed annual dose for workers, 100 mSv, was already higher than international standards. This has been increased in response to the Fukushima disaster to 250 mSv.

The U.S. National Academy of Sciences BEIR VII report estimates that each 1 mSv of radiation is associated with an increased risk of solid cancer (cancers other than leukemia) of about 1 in 10,000; an increased risk of leukemia of about 1 in 100,000; and a 1 in 17,500 increased risk of dying from cancer.

But a critical factor is that not everyone faces the same level of risk. For infants (under 1 year of age) the radiation-related cancer risk is 3 to 4 times higher than for adults; and female infants are twice as susceptible as male infants.

Females' overall risk of cancer related to radiation exposure is 40 percent greater than for males. Fetuses in the womb are the most radiation-sensitive of all.

The pioneering Oxford Survey of Childhood Cancer found that X-rays of mothers, involving doses to the fetus of 10-20 mSv, resulted in a 40 percent increase in the cancer rate among children up to age 15.

In Germany, a recent study of 25 years of the national childhood cancer register showed that even the normal operation of nuclear power plants is associated with a more than doubling of the risk of leukemia for children under 5 years old living within 5 kilometers of a nuclear plant.

Increased risk was seen to more than 50 km away. This was much higher than expected, and highlights the particular vulnerability to radiation of children in and outside the womb.

In addition to exposure measured by typical external radiation counters, the children of Fukushima will also receive internal radiation from particles inhaled and lodged in their lungs, and taken in through contaminated food and water.

A number of radioactive substances are concentrated up the food chain and in people. As a parent, as a physician, the decision to allow the children of Fukushima to be exposed to such injurious levels of radiation is an unacceptable abrogation of the responsibility of care and custodianship for our children and future generations.

(Tilman Ruff is chair of the International Campaign to Abolish Nuclear Weapons and associate professor at the Nossal Institute for Global Health at the University of Melbourne, Australia.)

Culture of Complicity Tied to Stricken Nuclear Plant

By [NORIMITSU ONISHI](#) and [KEN BELSON](#)

TOKYO — Given the fierce insularity of [Japan](#)'s nuclear industry, it was perhaps fitting that an outsider exposed the most serious safety cover-up in the history of Japanese nuclear power. It took place at Fukushima Daiichi, the plant that Japan has been struggling to get under control since last month's earthquake and tsunami.

In 2000, Kei Sugaoka, a Japanese-American nuclear inspector who had done work for General Electric at Daiichi, told Japan's main nuclear regulator about a cracked steam dryer that he believed was being concealed. If exposed, the revelations could have forced the operator, Tokyo Electric Power, to do what utilities least want to do: undertake costly repairs.

What happened next was an example, critics have since said, of the collusive ties that bind the nation's nuclear power companies, regulators and politicians.

Despite a new law shielding whistle-blowers, the regulator, the Nuclear and Industrial Safety Agency, divulged Mr. Sugaoka's identity to Tokyo Electric, effectively blackballing him from the industry. Instead of immediately deploying its own investigators to Daiichi, the agency instructed the company to inspect its own reactors. Regulators allowed the company to keep operating its reactors for the next two years even though, an investigation ultimately revealed, its executives had actually hidden other, far more serious problems, including cracks in the shrouds that cover reactor cores.

Investigators may take months or years to decide to what extent safety problems or weak regulation contributed to the disaster at Daiichi, the worst of its kind since Chernobyl. But as troubles at the plant

and fears over radiation continue to rattle the nation, the Japanese are increasingly raising the possibility that a culture of complicity made the plant especially vulnerable to the natural disaster that struck the country on March 11.

Already, many Japanese and Western experts argue that inconsistent, nonexistent or unenforced regulations played a role in the accident — especially the low seawalls that failed to protect the plant against the tsunami and the decision to place backup diesel generators that power the reactors' cooling system at ground level, which made them highly susceptible to flooding.

A 10-year extension for the oldest of Daiichi's reactors suggests that the regulatory system was allowed to remain lax by politicians, bureaucrats and industry executives **single-mindedly focused on expanding nuclear power**. Regulators approved the extension beyond the reactor's 40-year statutory limit just weeks before the tsunami **despite warnings about its safety and subsequent admissions by Tokyo Electric, often called Tepco, that it had failed to carry out proper inspections of critical equipment**.

The mild punishment meted out for past safety infractions has reinforced the belief that nuclear power's main players are more interested in protecting their interests than increasing safety. In 2002, after Tepco's cover-ups finally became public, its chairman and president resigned, only to be given advisory posts at the company. Other executives were demoted, but later took jobs at companies that do business with Tepco. Still others received tiny pay cuts for their role in the cover-up. And after a temporary shutdown and repairs at Daiichi, Tepco resumed operating the plant.

In a telephone interview from his home in the San Francisco Bay Area, Mr. Sugaoka said, "I support nuclear power, but I want to see complete transparency."

Revolving Door

In Japan, the **web of connections between the nuclear industry and government** officials is now popularly referred to as the "nuclear power village." The expression connotes the nontransparent, collusive interests that underlie the establishment's push to increase nuclear power despite the discovery of active fault lines under plants, new projections about the size of tsunamis and a long history of cover-ups of safety problems.

Just as in any Japanese village, the like-minded — nuclear industry officials, bureaucrats, politicians and scientists — have prospered by rewarding one another with construction projects, lucrative positions, and political, financial and regulatory support. The few openly skeptical of nuclear power's safety become village outcasts, losing out on promotions and backing.

Until recently, it had been considered political suicide to even discuss the need to reform an industry that appeared less concerned with safety than maximizing profits, said Kusuo Oshima, one of the few governing Democratic Party lawmakers who have long been critical of the nuclear industry.

"Everyone considered that **a taboo**, so nobody wanted to touch it," said Mr. Oshima, adding that he could speak freely because he was backed not by a nuclear-affiliated group, but by Rissho Kosei-Kai, one of Japan's largest lay Buddhist movements.

"It's all about money," he added.

At Fukushima Daiichi and elsewhere, critics say that safety problems have stemmed from a common source: a watchdog that is a member of the nuclear power village.

Though it is charged with oversight, the Nuclear and Industrial Safety Agency is part of the Ministry of Trade, Economy and Industry, the bureaucracy charged with promoting the use of nuclear power. Over a long career, officials are often transferred repeatedly between oversight and promotion divisions, **blurring the lines between supporting and policing the industry.**

Influential bureaucrats tend to side with the nuclear industry — and the promotion of it — because of a practice known as amakudari, or descent from heaven. Widely practiced in Japan's main industries, amakudari allows senior bureaucrats, usually in their 50s, to land cushy jobs at the companies they once oversaw.

According to data compiled by the Communist Party, one of the fiercest critics of the nuclear industry, generations of high-ranking officials from the ministry have landed senior positions at the country's 10 utilities since Japan's first nuclear plants were designed in the 1960s. In a pattern reflective of the clear hierarchy in Japan's ministries and utilities, the ministry's most senior officials went to work at Tepco, while those of lower ranks ended up at smaller utilities.

At Tepco, from 1959 to 2010, four former top-ranking ministry officials successively served as vice presidents at the company. When one retired from Tepco, his junior from the ministry took over what is known as the ministry's "reserved seat" of vice president at the company.

In the most recent case, a director general of the ministry's Natural Resources and Energy Agency, Toru Ishida, left the ministry last year and joined Tepco early this year as an adviser. Prime Minister [Naoto Kan](#)'s government initially defended the appointment but reversed itself after the Communist Party publicized the extent of amakudari appointments since the 1960s. Mr. Ishida, who would have normally become vice president later this year, was forced to step down last week.

Kazuhiro Hasegawa, a spokesman for Tepco, denied that it was an amakudari appointment, adding that the company simply hired the best people. The company declined to make an executive available for an interview about the company's links with bureaucrats and politicians.

Lower-ranking officials also end up at similar, though less lucrative, jobs at the countless companies affiliated with the power companies, as well as advisory bodies with close links to the ministry and utilities.

"Because of this collusion, the Nuclear and Industrial Safety Agency ends up becoming a member of the community seeking profits from nuclear power," said Hidekatsu Yoshii, a Communist Party lawmaker and nuclear engineer who has long followed the nuclear industry.

Collusion flows the other way, too, in a lesser-known practice known as amaagari, or ascent to heaven. Because the regulatory panels meant to backstop the Nuclear and Industrial Safety Agency lack full-time technical experts, they depend largely on retired or active engineers from nuclear-industry-related companies. They are unlikely to criticize the companies that employ them.

Even academics who challenge the industry may find themselves shunned. As Japan has begun looking into the problems surrounding collusion since March 11, the Japanese news media has highlighted the discrimination faced by academics who raised questions about the safety of nuclear power.

In Japan, research into nuclear power is financed by the government or nuclear power-related companies. Unable to conduct research, skeptics, especially a group of six at Kyoto University, languished for decades as assistant professors.

One, Hiroaki Koide, a nuclear reactor expert who has held a position equivalent to assistant professor for 37 years at Kyoto University, said he applied unsuccessfully for research funds when he was younger.

“They’re not handed out to outsiders like me,” he said.

In the United States, the [Nuclear Regulatory Commission](#), the main regulatory agency for the nuclear power industry, can choose from a pool of engineers unaffiliated with a utility or manufacturer, including those who learned their trade in the Navy or at research institutes like Brookhaven or Oak Ridge.

As a result, the N.R.C. does not rely on the industry itself to develop proposals and rules. In Japan, however, the Nuclear and Industrial Safety Agency lacks the technical firepower to draw up comprehensive regulations and tends to turn to industry experts to provide that expertise.

The agency “has the legal authority to regulate the utilities, but significantly **lacks the technical capability to independently evaluate what they propose**,” said Satoshi Sato, who has nearly 30 years’ experience working in the nuclear industry in the United States and Japan. “Naturally, the regulators tend to avoid any risk by proposing their own ideas.”

Inspections are not rigorous, Mr. Sato said, because agency inspectors are not trained thoroughly, and safety standards are watered down to meet levels that the utilities can financially bear, he and others said.

Dominion in Parliament

The political establishment, one of the great beneficiaries of the nuclear power industry, has shown little interest in bolstering safety. In fact, critics say, lax oversight serves their interests. Costly renovations get in the way of building new plants, which create construction projects, jobs and generous subsidies to host communities.

The Liberal Democrats, who governed Japan nearly without interruption from 1955 to 2009, have close ties to the management of nuclear-industry-related companies. The Democratic Party, which has governed since, is backed by labor unions, which, in Japan, tend to be close to management.

“Both parties are captive to the power companies, and they follow what the power companies want to do,” said Taro Kono, a Liberal Democratic lawmaker with a reputation as a reformer.

Under Japan's electoral system, in which a significant percentage of legislators is chosen indirectly, parties reward institutional backers with seats in Parliament. In 1998, the Liberal Democrats selected Tokio Kano, a former vice president at Tepco, for one of these seats.

Backed by Keidanren — Japan's biggest business lobby, of which Tepco is one of the biggest members — Mr. Kano served two six-year terms in the upper house of Parliament until 2010. In a move that has raised eyebrows even in a world of cross-fertilizing interests, he has returned to Tepco as an adviser.

While in office, Mr. Kano led a campaign to reshape the country's energy policy by putting nuclear power at its center. He held leadership positions on energy committees that recommended policies long sought by the nuclear industry, like the use of a fuel called mixed oxide, or mox, in fast-breeder reactors. He also opposed the deregulation of the power industry.

In 1999, Mr. Kano even complained in Parliament that nuclear power was portrayed unfairly in government-endorsed school textbooks. "Everything written about [solar energy](#) is positive, but only negative things are written about nuclear power," he said, according to parliamentary records.

Most important, in 2003, on the strength of Mr. Kano's leadership, Japan adopted a national basic energy plan calling for the growth of [nuclear energy](#) as a way to achieve greater energy independence and to reduce Japan's emission of greenhouses gases. The plan and subsequent versions mentioned only in broad terms the importance of safety at the nation's nuclear plants despite the 2002 disclosure of cover-ups at Fukushima Daiichi and a 1999 accident at a plant northeast of Tokyo in which high levels of radiation were spewed into the air.

Mr. Kano's legislative activities drew criticism even from some members of his own party.

"He rewrote everything in favor of the power companies," Mr. Kono said.

In an interview at a Tepco office here, accompanied by a company spokesman, Mr. Kano said he had served in Parliament out of "conviction."

"It's disgusting to be thought of as a politician who was a company errand boy just because I was supported by a power company and the business community," Mr. Kano said.

Taking on a Leviathan

So entrenched is the nuclear power village that it easily survived postwar Japan's biggest political shake-up. When the Democratic Party came to power 20 months ago, it pledged to reform the nuclear industry and strengthen the Nuclear and Industrial Safety Agency.

Hearings on reforming the agency were held starting in 2009 at the Ministry of Economy, Trade and Industry, said Yosuke Kondo, a lawmaker of the governing Democratic Party who was the ministry's deputy minister at the time. But they fizzled out, he said, after a new minister was appointed in September 2010.

The new minister, Akihiro Ohata, was a former engineer at Hitachi's nuclear division and one of the most influential advocates of nuclear power in the Democratic Party. He had successfully lobbied his party to change its official designation of nuclear power from a "transitional" to "main" source of

energy. An aide to Mr. Ohata, who became Minister of Land, Infrastructure, Transport and Tourism in January, said he was unavailable for an interview.

As moves to strengthen oversight were put on the back burner, the new government dusted off the energy plan designed by Mr. Kano, the Tepco adviser and former lawmaker. It added fresh details, including plans to build 14 new reactors by 2030 and raise the share of electricity generated by nuclear power and minor sources of clean energy to 70 percent from 34 percent.

What is more, Japan would make the sale of nuclear reactors and technology the central component of a long-term export strategy to energy-hungry developing nations. A new company, the **International Nuclear Energy Development of Japan**, was created to do just that. Its shareholders were made up of the country's nine main nuclear plant operators, three manufacturers of nuclear reactors and the government itself.

The nuclear power village was **going global** with the new company. The government took a 10 percent stake. Tepco took the biggest, with 20 percent, and one of its top executives was named the company's first president.

Female worker at nuke plant suffers radiation dose exceeding limit

TOKYO, April 27, Kyodo

Tokyo Electric Power Co. said Wednesday that one of its female employees at the crisis-hit Fukushima Daiichi nuclear power plant was exposed to radiation exceeding three times the legal limit of 5 millisieverts in a three-month period.

Fukushima city removing radioactive topsoil in schools

KORIYAMA, Japan, April 27, Kyodo

A city in Fukushima Prefecture started Wednesday to remove topsoil from playgrounds in its elementary and nursery schools, following radiation leaks from a crisis-hit nuclear power plant nearby.

Heavy machinery began scooping off surface soil at Kaoru Elementary School and Tsurumidan Nursery School in Koriyama, city officials said, adding that the removed soil will be **discarded in landfills in the inland city**.

The work is part of a project to remove the upper layer of soil at 15 elementary and junior high schools, where radiation levels have been measured at **over 3.8 microsieverts per hour**, as well as 13 nursery schools, where levels of **over 3.0 microsieverts** per hour have been detected, the city officials said.

EPCO filling containment vessels; experts raise doubts

"The water level at the No. 1 reactor has been raised to about 6 meters above the bottom of the containment vessel. That level is 3 meters below the bottom of the pressure vessel.

But TEPCO has been unable to verify the water levels at the No. 2 and No. 3 reactors, and suspect that water is leaking from the damaged containment vessels." [Asahi](#)

Petition to stop increasing radiation for Fukushima's children

From the petition: "We urgently demand the withdrawal of the Japanese Government's inhumane decision to force 20mSv per year radiation exposure onto children.

"On April 19th, the Ministry of Education, Culture, Sports, Science and Technology (MEXT) notified the Board of Education and related institutions in Fukushima Prefecture the level of 20 millisieverts per year (mSv/y) as a Radiation Safety Standard for schools in Fukushima Prefecture. This is the standard to be used for school grounds and buildings.

"...The Labour Standards Act prohibits those under the age of 18 from working under these conditions. Forcing children to be exposed to such radiation doses is an exceedingly inhumane decision. Therefore, we condemn this in the strongest terms.

"20 mSv/y is comparable to the [legally] recognized dose for inducing leukemia in nuclear power plant workers. It is also comparable to the maximum dose allowed for nuclear power plant workers in Germany." Also see the Japan Federation of Bar Associations [statement](#) opposing this level of radiation exposure. Beyond Nuclear has released a [press statement](#) today. [Sign the petition](#).

Female worker at nuke plant suffers radiation dose exceeding limit

By Miya Tanaka
TOKYO, April 28, Kyodo

Tokyo Electric Power Co. said Wednesday that one of its female employees was exposed to radiation doses **far above the legal limit** at the crisis-hit Fukushima Daiichi nuclear power plant -- the latest revelation of lax radiation management by the plant operator since the crisis erupted last month.

As a key step to bringing an end to the ongoing crisis, the utility said, meanwhile, it will seek to start in June decontamination of highly radioactive water accumulating in the plant's premises, which has prevented restoration work as a side effect of the emergency water injection into troubled reactors from outside in place of their lost cooling functions.

TEPCO as the firm is known also started to increase the amount of water injected into the damaged No. 1 reactor core in preparation to flood the reactor's primary containment vessel to cool the fuel inside in a stable manner.

Japan to scrap workers' annual radiation dose limit at normal times

TOKYO, April 28, Kyodo

The health ministry plans to scrap the annual radiation dose limit for nuclear power plant workers at normal times for the meantime **to secure enough workers** for maintenance and checkups of nuclear power plants other than the crisis-hit Fukushima power station, sources close to the matter said Wednesday.

Increased water injection into No. 1 reactor yields positive signs

TOKYO, April 28, Kyodo

The injection of increased amounts of coolant water into the damaged No. 1 reactor core at the crisis-hit Fukushima Daiichi nuclear plant has yielded positive signs, with both the temperature and pressure inside the reactor vessel falling as expected, the government's nuclear agency said Thursday.

The plant operator Tokyo Electric Power Co. began raising the amount of water Wednesday morning from 6 tons per hour to 10 tons in preparation for flooding the reactor's primary containment vessel to cool the fuel in a stable manner. The utility known as TEPCO will keep injecting the current amount until Thursday evening, it said.

Hidehiko Nishiyama, a spokesman for the Nuclear and Industrial Safety Agency, said TEPCO initially planned to increase the amount of water to 14 tons per hour, but decided to keep pouring 10 tons per hour so as not to cause abnormalities.

<http://www.iaea.org/newscenter/news/tsunamiupdate01.html>

1. Current situation (27 avril)

Overall, the situation at the Fukushima Daiichi nuclear power plant remains very serious, but there are signs of recovery in some functions, such as electrical power and instrumentation.

TOKYO (Kyodo) -- The health ministry plans to scrap the annual radiation dose limit for nuclear power plant workers at normal times for the meantime to secure enough workers for maintenance and checkups of nuclear power plants other than the crisis-hit Fukushima power station, sources close to the matter said Wednesday.

Under Japanese law, nuclear workers cannot be exposed to more than 50 millisieverts in one year and more than 100 millisieverts over five years.

The ministry, however, is expected to maintain the 100-millisievert rule, as there is medical evidence that exposure to radiation exceeding 100 millisieverts could increase the risk of developing leukemia and cancer, according to the sources.

The move comes as many nuclear workers are being sent to deal with the emergency situation at the radiation-leaking Fukushima Daiichi nuclear power plant, although there are only 70,000 people nationwide who can engage in work at such plants.

As workers would not be able to work at other plants once they exceed their radiation dose limit by dealing with the Fukushima crisis, the industry ministry has been calling on the Ministry of Health, Labor and Welfare to ease the limit to prevent a possible shortage of such workers.

To cope with the Fukushima crisis, the health ministry raised the legal limit on the amount of radiation to which each worker could be exposed in an emergency situation to 250 millisieverts from 100 millisieverts on March 15. But the limit for nuclear workers at normal times was not changed.

In this photo from a footage of a live camera released by Tokyo Electric Power Co. (TEPCO), black smoke billows from the crippled Fukushima No. 1 Nuclear Power Plant in Okumamachi, northeastern Japan, on March 22, 2011. (AP)

In the United States, the limit for civilians is 100 millisieverts in an emergency situation. Civilians should not be exposed to more than 50 millisieverts annually in normal times and more than 100 millisieverts over five years.

Tokyo Electric Power Co., which owns the crippled Fukushima Daiichi power station, said that 30 people who worked at the plant were exposed to 100 millisieverts or more.

(Mainichi Japan) April 28, 2011

High levels of radiation in areas near nuclear plant foreseen for a year

The Japanese government unveiled a map of radioactive contamination on April 26, predicting residents in areas near the troubled nuclear power plant could be exposed to radiation far greater than permissible levels.

According to the contamination map unveiled by the Ministry of Education, Culture, Sports, Science and Technology, a cumulative dose of radiation for the year to March 11, 2012 is expected to reach 235.4 millisieverts in Akogi Kunugidaira in Namie, Fukushima Prefecture, 24 kilometers northwest of the Fukushima No. 1 Nuclear Power Plant.

The cities of Fukushima and Minami-Soma are also predicted to receive more than 10 millisieverts of radiation, 10 times the dose of artificial radiation an ordinary person is allowed to be exposed to a year.

Based on data collected from 2,138 monitoring points, the ministry calculated total cumulative doses of radiation between March 12 and April 21 and added them up to expected cumulative doses of radiation for the period thereafter to March 11, 2012.

Expected radiation exposure was based on the assumption that the nuclear power plant continues to spew the same level of radiation as that detected on April 22. The ministry assumed that people in each monitoring point spend eight hours outdoors and 16 hours inside wooden houses a day. The ministry assumes the level of exposure to radiation in wooden houses is 40 percent lower than outdoors.

Increased water injection helping to cool No. 1 reactor faster

TOKYO, April 28, Kyodo

The operator of the crippled Fukushima Daiichi nuclear plant said Thursday that the injection of more water is helping to cool the No. 1 reactor core faster and there appears to be no major leakage so far from the No. 4 unit's spent fuel storage pool.

Radiation adviser to Kan to quit over gov't nuke crisis response

TOKYO, April 29, Kyodo

An adviser to Prime Minister Naoto Kan on the nuclear crisis at the Fukushima Daiichi power plant told the prime minister's office Friday he will resign in protest over what he called the

Prediction system found useless in nuke emergency, evacuation plans

In this image made on Friday, April 15, 2011, the Lonngmen Nuclear Power Plant is seen behind Fulong beach in Gongliao Township, northeastern Taiwan. As China, Taiwan.

TOKYO (Kyodo) -- Japan's multi-billion-yen system for predicting the dispersal of radioactive materials has proven to be of not much help in the ongoing crisis at the Fukushima Daiichi nuclear power plant, drawing sharp criticism of the government of Prime Minister Naoto Kan.

Data from the System for Prediction of Environmental Emergency Dose Information, or SPEEDI, were released only twice in the first six weeks after March 11, when the massive earthquake and tsunami crippled the nuclear plant in northeastern Japan.

In sharp contrast, some overseas research institutes made their own estimates public, although with the proviso that as the amount of radioactive materials spewed from the plant was unknown, the actual diffusive concentrations could be different.

Receiving flak, the Nuclear Safety Commission, which supervises SPEEDI, began releasing hour-by-hour data only in late April. But even so, the Japanese government's ability to adequately use the information remains in question, experts say.

This March 24, 2011 aerial photo taken by a small unmanned drone and released by AIR PHOTO SERVICE shows damaged Unit 4 of the crippled Fukushima Dai-ichi nuclear power plant in Okumamachi, Fukushima prefecture, northern Japan. (AP Photo/AIR PHOTO SERVICE)

The system forms part of the disaster-prevention policy established by the commission for nuclear power facilities.

It is designed to speedily calculate the dispersal of radioactive substances emitted in the air and the predicted amount of radiation to help the state and local governments in their disaster-prevention measures.

More than 30 years have passed since the development of SPEEDI started, and its development and maintenance have cost a total of about **12.8 billion yen**. In this fiscal year, about 770 million yen is earmarked for its budget.

Before the commission made available hourly measurements, it released SPEEDI data regarding the Fukushima accident only twice -- on March 23 and April 11. The figures were for the amounts of radioactive materials already released and their dispersal, but did not include a prediction for the future.

This was because data about the nuclear reactors and radioactive substances needed for making a prediction became unavailable after the plant lost power supply due to the earthquake and tsunami, the commission said.

This March 24, 2011 aerial photo taken by a small unmanned drone and released by AIR PHOTO SERVICE shows damaged Unit 3 of the crippled Fukushima Dai-ichi nuclear power plant in Okumamachi, Fukushima Prefecture, northeastern Japan. (AP Photo/AIR PHOTO SERVICE)

Commission Chairman Haruki Madarame said SPEEDI was created on the premise that such information as the emission amounts of radioactive materials would always be available, and admitted the system's inadequacy, saying, "It cannot be used in an (information-lacking) case like this one."

An official at the disaster countermeasures headquarters at the Fukushima prefectural government said, "It is very regrettable. We could have avoided unnecessary turmoil in evacuating residents if the diffusion prediction had been grounded."

Although an exact diffusion prediction could not be made, the system calculated an accurate trend -- to some extent -- for the spread of radioactive materials by carrying out an estimate based on hypothetical conditions, according to the commission.

The commission thought a massive amount of radioactive materials was emitted when the power plant's No. 2 reactor's container vessel was damaged March 15 by a hydrogen explosion. It then estimated the following day the amount of released radioactive materials based on the meteorological data on the day of the explosion. But this information was not made public immediately.

When making public the result of the estimate for the first time on March 23, Madarame said, "I hesitated to make such an announcement because it would cause social turmoil," showing a lack of trust in how people would react to such information.

In this photo released by Tokyo Electric Power Co. (TEPCO) , workers in protective suits conduct cooling operation by spraying water at the damaged No. 4 unit of the Fukushima Dai-ichi nuclear complex in Okumamachi, northeastern Japan, Tuesday, March 22, 2011. (AP Photo/Tokyo Electric Power Co.)

The system's data were used as a basis when the government raised the severity level of the Fukushima nuclear crisis on April 12 from level 5 to the most serious level 7 on the International Nuclear Event Scale. But the safety commission was again hesitant to make the information public.

When North Korea carried out a nuclear test in 2006 and a volcano on Japan's Miyakejima Island erupted in 2000, predictions by SPEEDI about the diffusion of radioactive substances and volcanic gases were unveiled.

The government's initial failure to release the SPEEDI data in the Fukushima accident invites the suspicion that it was trying to conceal information that was negative for the domestic nuclear industry, experts say.

The data obtained by SPEEDI are jointly owned with local governments which shoulder the maintenance costs for the system. This time, the local governments in the disaster-hit areas were unable to get information when they needed it the most.

Hitoshi Yoshioka, a professor at Kyushu University, said, "If there were estimate dispersal figures, they should have been fully explained and positively made public even if they lacked credibility to some degree."

In this photo released by Tokyo Electric Power Co. (TEPCO), gray smoke rises from Unit 3 of the tsunami-stricken Fukushima Dai-ichi nuclear power plant in Okumamachi, Fukushima Prefecture, Japan, Monday, March 21, 2011. (AP Photo/Tokyo Electric Power Co.)

The reason why the government judged that people could not understand such information and did not make it public immediately was a fear of criticism of nuclear power governance, he said.

"The government is asked to fundamentally review SPEEDI's original function of the dispersal prediction for radioactive materials," he added.

(Mainichi Japan) April 29, 2011

Radiation exposure level nears limit for 1 worker at Fukushima plant

TOKYO, April 30, Kyodo

Tokyo Electric Power Co. said Saturday that the level of radiation exposure for one of its employees came close to the legal yearly limit of 250 millisieverts at the crisis-hit Fukushima Daiichi nuclear power plant.

TEPCO, as the firm is known, said it found that the amount of internal and external radiation exposures of one of its employees working at the plant, crippled by the March 11 killer earthquake and ensuing tsunami, had reached 240.8 millisieverts in total, while another received 226.6 millisieverts.

Under Japanese law, nuclear workers cannot be exposed to more than 250 millisieverts per year in an emergency situation. To cope with the Fukushima crisis, the Ministry of Health, Labor and Welfare raised the legal limit of radiation that each worker could be exposed to in such situation from 100 millisieverts on March 15.

Cabinet nuclear advisor resigns in protest over government response to plant crisis

University of Tokyo Professor Toshiso Kosako is pictured during a press conference held at the Diet building on April 29, 2011, following his resignation as a special nuclear advisor to the Cabinet. (Mainichi)

A nuclear advisor to the Cabinet has resigned in protest against government stopgap measures that deal with the ongoing nuclear crisis in Fukushima Prefecture.

Toshiso Kosako, 61, a University of Tokyo professor specializing in radiation safety, submitted a letter of resignation to the Prime Minister's Office on April 29.

During a press conference held at the Diet building later that day, Kosako, who was named a special advisor to Prime Minister Naoto Kan on March 16, criticized the government's handling of the crisis at the Fukushima No. 1 Nuclear Power Plant as shortsighted.

In particular, Kosako protested against the government's decision to revise the maximum permissible level of radiation exposure among children up to 20 millisieverts per year, saying, "Should I approve that decision, I would no longer be a researcher. I would not want my children to be exposed to that amount of radiation."

Kosako revealed the Cabinet did not accept his advice that outdoor school activities for elementary and junior high school students near the crippled power station be restricted to prevent them from being exposed to over 1 millisievert of radiation per year.

"It is quite rare for nuclear power plant workers dealing with radioactive materials to be exposed to 20 millisieverts of radiation per year. I cannot allow infants and children to be exposed to such high levels of radiation from an academic as well as humanitarian point of view."

He also pointed out that the government was slow in applying the System for Prediction of Environmental Emergency Dose Information (SPEEDI) and disclosing its data, even though nuclear safety guidelines stipulate the system be implemented immediately in an emergency. "The government has ignored the law and taken stopgap measures, failing to bring the crisis under control promptly," he said.

Seiki Soramoto, Democratic Party of Japan (DPJ) member of the House of Representatives, also attended the press conference and said, "I want to drive the situation in the right direction by telling my fellow lawmakers that it's a mistake that the government set the radiation exposure limit for children at 20 millisieverts per year."

Soramoto, one of the DPJ lawmakers close to former party head Ichiro Ozawa, had been working on the issue in collaboration with Kosako.

During a House of Representatives Budget Committee meeting on April 30, Kan, who appointed six nuclear experts and others as special advisors on the Fukushima crisis after the March 11 disasters, responded, "The government has taken into account the opinions of special advisors in making the decision. I don't believe our response was shortsighted."

Radiation level of 1,120 millisieverts per hour detected in damaged reactor building

Evacuees are screened for radiation contamination at a testing center Tuesday, March 15, 2011, in Koriyama city, Fukushima Prefecture, northern Japan, four days after a massive earthquake and tsunami struck the country's north east coast. (AP Photo/Wally Santana)

A **high radiation level of 1,120 millisieverts per hour** was detected within the damaged No. 1 reactor building at the Fukushima No. 1 Nuclear Power Plant when robots photographed the area on April 26, it has been learned.

The level is the highest detected in the reactor building to date. The plant's operator, Tokyo Electric Power Co. (TEPCO), plans to fill the nuclear reactor containment vessel with water to contain radiation emissions, and is trying to cool down the reactor, but the high levels of radiation in the building are hampering work and are likely to cause difficulties for the company in achieving its goal of bringing the crisis at the plant under control within "six to nine months."

Two robots were used to photograph the area near the pump room on the first floor of the No. 1 reactor building and measure radiation. The pump room contains a heat exchanger that is used to cool water containing residual heat that is emitted when the nuclear reactors are stopped, and a pump to circulate cooling water.

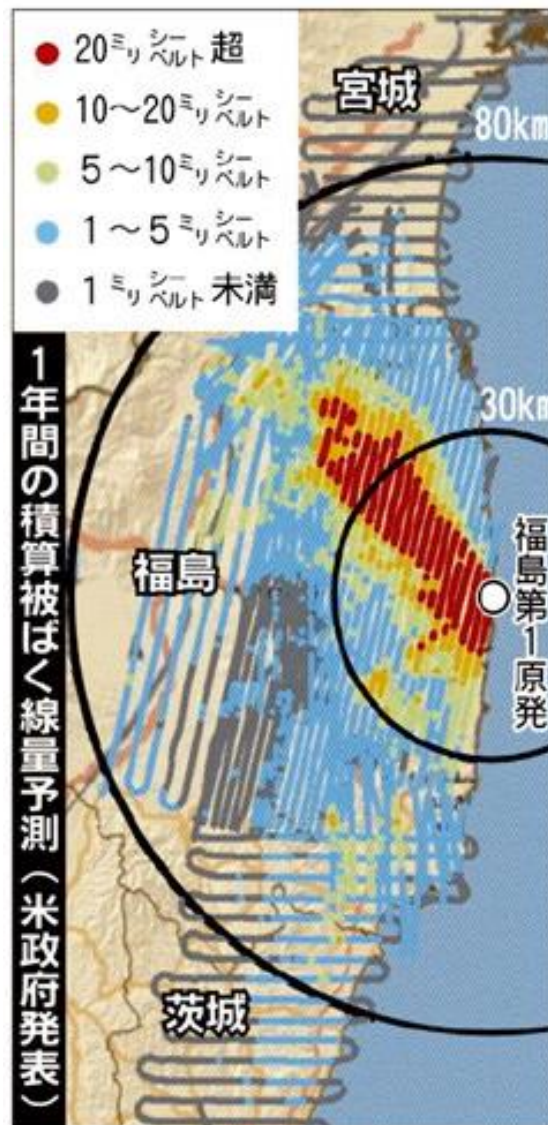

"It's possible that reactor water containing radioactive materials seeped into pipes due to valve problems," a TEPCO representative commented.

Initially, TEPCO planned to use the reactor's residual heat removal system to restore circulatory cooling functions, but as high levels of radiation were detected near the entrance of the pump room, the company is considering other options.

"Operations going through the pump room would be difficult. We want to establish an alternative route," TEPCO manager Junichi Matsumoto said.

On April 27, TEPCO began inspections to determine whether it will be possible to fill the containment vessel with water, increasing the amount of water pumped into the reactor in stages.

Mainichi Daily News 28.04.2011

The NNSA hazard map released by the U.S. federal government. The Fukushima No. 1 Nuclear Power Plant is marked by a white dot at right.

"At present, no water is leaking onto the floor, so we will continue to pump water into the reactor," Matsumoto said.

Under the Nuclear Reactor Regulation Law and the Industrial Safety and Health Act, the maximum permitted exposure to radiation is 100 millisieverts over a period of five years or 50 millisieverts per year. But a provision in the general rules stipulates that 100 millisieverts can be added to the maximum exposure level in times of emergencies.

The government has taken the special step of raising the limit to 250 millisieverts for the crisis at the Fukushima nuclear power station.

MAI 2011

Another female worker at nuke plant exposed to radiation above limit

TOKYO, May 1, Kyodo

Tokyo Electric Power Co. said Sunday that a second female radiation worker at the crisis-hit Fukushima Daiichi nuclear power plant has been exposed to radiation exceeding the legal limit, after news of the first was reported Thursday.

The worker has no health problems so far and will be seen by a doctor on Monday, it added.

The woman in her 40s has been exposed to a total of 7.49 millisieverts of radiation, against the legal limit for female workers of 5 millisieverts for a three-month period, when she was working at the six-reactor complex following the March 11 earthquake and ensuing tsunami which hit the plant, the utility operating the plant said.

Radiation exposure levels near limit for 2 Fukushima nuke workers

Mainichi News

(AP Photo/Mark Baker)

TOKYO (Kyodo) -- As the nuclear crisis continues at the Fukushima Daiichi power plant, two workers, who were previously hospitalized for possible radiation burns, turned out Saturday to have been exposed to radiation levels close to the limit of 250 millisieverts while seven women in affected areas were found with slightly contaminated breast milk.

Plant operator Tokyo Electric Power Co. said the same day that it will build a makeshift breakwater possibly by mid-June to prevent any tsunami from a huge aftershock from further damaging the plant, while plugging up underground trenches on the premises with concrete by late May to prevent contaminated water from leaking again into the sea.

The two workers have been exposed to 240.8 millisieverts and 226.6 millisieverts of radiation, respectively, when internal exposure is taken into account, among 21 workers exposed to over 100 millisieverts of external radiation since the crisis erupted following the magnitude 9 quake and tsunami, it said.

Under Japanese law, the Ministry of Health, Labor and Welfare has limited by an ordinance radiation exposure of each nuclear plant worker at 100 millisieverts a year in an emergency situation, but raised the limit to 250 millisieverts to cope with the Fukushima crisis on March 15.

The two were hospitalized for possible radiation burns to their feet after standing in water that contained radioactive materials 10,000 times the normal level while laying a cable underground at the troubled plant on March 24, the utility known as TEPCO said.

The latest revelation came after the firm checked internal exposure of the 21 workers, of whom eight others were exposed to a total of 150-200 millisieverts and the remaining 11 were exposed to 100-150 millisieverts.

In this photo released by Nuclear and Industrial Safety Agency, Tokyo Electric Power Co. workers collect data in the control room for Unit 1 and Unit 2 at the tsunami-crippled Fukushima No. 1 Nuclear Power Plant in Okumamachi, Fukushima Prefecture, on March 23, 2011.(AP)

The health ministry said the same day its survey of breast milk on 23 women in Tokyo and four prefectures, including Fukushima and its neighboring Ibaraki, found 2.2 to 8.0 becquerels of radioactive substances per kilogram in seven of them but that the amounts pose no health risks to their babies.

Of the seven, 3.5 becquerels of iodine and 2.4 becquerels of cesium were detected in milk taken from one who lived within 30 kilometers from the nuclear plant until March 14 after the March 11 quake and tsunami triggered the crisis there. The others live in Ibaraki and Chiba prefectures.

Samples of milk were taken from the women in their 20s to 30s at obstetric clinics over the five days through Thursday in response to a civic group's announcement on April 20 that 36.3 becquerels of iodine was found in breast milk of a woman in Chiba Prefecture, compared with the interim limits set under the Food Sanitation Law of 100 becquerels of iodine and 200 becquerels of cesium for milk and dairy products.

Located on the Pacific coast some 220 km from Tokyo, the Fukushima Daiichi Nuclear Power Station has spewed radioactive materials, causing concerns about human health in the prefecture and other northeastern and eastern Japan prefectures.

The amount of iodine contaminating the sea is expected to fall to the undetectable level of below 10 becquerels per liter by early May and that of cesium by early June, the Ministry of Education, Culture, Sports, Science and Technology said based on supercomputer simulations.

But the forecast was of no help for affected fishers in Ibaraki, who said the same day they would give up the season's catch of young sand lance, having voluntarily refrained from catching the fry by request from the prefectural government when they were about to start their fishing.

TEPCO Vice President Norio Tsuzumi and other officials again apologized Saturday as they visited the affected municipalities of Iitate and Kawamata in Fukushima where all and some residents, respectively, are required to evacuate by late May.

In this photo released by Nuclear and Industrial Safety Agency, Tokyo Electric Power Co. workers collect data in the control room for Unit 1 and Unit 2 at the tsunami-crippled Fukushima No. 1 Nuclear Power Plant in Okumamachi, Fukushima Prefecture, on March 23, 2011. (AP)

In a related development, the government's advisory Nuclear Safety Commission was found the same day to have endorsed a controversial antiradiation measure proposed by the education ministry in just two hours without proper procedures on April 19, government sources said.

Under the measure, schoolchildren and kindergarteners would be limited from outdoor activities when the radiation level reaches 20 millisieverts per year -- 20 times the limit for people to be safely exposed.

The commission's endorsement of the measure was one reason Toshiso Kosako, professor on antiradiation safety measures at the University of Tokyo's graduate school, said he would resign Friday as an adviser to Prime Minister Naoto Kan on the ongoing nuclear crisis.

(Mainichi Japan) May 1, 2011

U.S. medical group blasts Tokyo radiation policy on Fukushima children

TOKYO, May 2, Kyodo

Physicians for Social Responsibility, a U.S. nonprofit organization of medical experts, has condemned as "unconscionable" the Japanese government's safety standards on radiation levels at elementary and middle schools in nuclear disaster-stricken Fukushima Prefecture.

The PSR statement directly challenges the Japanese government stance that it is safe for schoolchildren to use playgrounds on school premises in the prefecture as long as the dose they are exposed to does not exceed 20 millisieverts over a year.

The PSR view is also in line with that voiced by Toshiso Kosako, who said Friday he would step down as an adviser to Prime Minister Naoto Kan on the Fukushima nuclear crisis in protest. The University of Tokyo professor urged the government to toughen guidelines on upper limits on radiation levels the education ministry recently announced for primary school playgrounds in Fukushima.

Work starts to install air filter to reduce radiation at nuke plant

TOKYO (Kyodo) -- The operator of the crisis-hit Fukushima Daiichi power plant on Monday started work to install an air filter in the building housing the No. 1 reactor to reduce the high radiation level and enable workers to enter and create a system to cool the troubled reactor.

Meanwhile, it was revealed the same day that Japan's system to predict the volume of radioactive materials that would be released into the environment in the event of a nuclear accident failed to work when the March 11 quake and ensuing tsunami hit Fukushima because the plant lost power, according to sources close to the matter.

It has already been revealed that another system for predicting the dispersal of radioactive materials has been of little use in the ongoing crisis. A total of 28 billion yen has been spent on developing and maintain the two systems.

In this photo released by Nuclear and Industrial Safety Agency, Tokyo Electric Power Co. workers collect data in the control room for Unit 1 and Unit 2 at the tsunami-crippled Fukushima No. 1 Nuclear Power Plant in Okumamachi, Fukushima Prefecture, on March 23, 2011. (AP)

The disaster at the Fukushima nuclear power plant is the country's worst nuclear accident, with plant operator Tokyo Electric Power Co. saying that it will take at least six months before the utility can stabilize the plant's troubled reactors.

The utility known as TEPCO is currently trying to restore stable cooling functions to the reactors, and reducing the radiation level inside the No. 1 reactor building is seen as a key step toward that end.

"We have to improve the condition in the reactor building in terms of radiation, so that we can install equipment...to create a cooling system," Hidehiko Nishiyama, a spokesman for the government's Nuclear and Industrial Safety Agency, told a press conference in the afternoon.

TEPCO is hoping to start ventilating the air in the building as early as Thursday, according to TEPCO officials.

Under the utility's plan, the No. 1 reactor's primary containment vessel is expected to be filled with water to a level above the reactor fuel placed inside the pressure vessel.

Reactor fuel is placed inside a pressure vessel, which is contained in a round-bottomed, flask-shaped primary containment vessel. Each reactor building houses these vessels.

(Mainichi Japan) May 2, 2011

TEPCO faces uphill battle in filling nuclear reactor containment vessel with water

Tokyo Electric Power Co. (TEPCO) is struggling to carry out its plans to fill the containment vessel of the Fukushima No. 1 Nuclear Power Plant's No. 1 reactor with water to control radiation emissions, it has emerged.

Workers have already pumped in more than enough water to fill the containment vessel, but they have not actually seen a rise in the water level. Furthermore, when workers increased the amount of water pumped into the containment vessel, pressure inside the vessel fell, threatening a hydrogen explosion. As a result, workers had to once again reduce the amount of water. When pressure inside the containment vessel falls to a level near regular atmospheric pressure, oxygen can enter the container from outside and react with hydrogen inside to produce an explosion.

In this image from video footage taken Tuesday, April 26, 2011 by a PackBot and released Wednesday, April 27, 2011 by Tokyo Electric Power Co., another PacBot works inside the nuclear reactor building of Unit 1 at the

Fukushima Dai-ich nuclear power plant in Okuma, Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

In a news conference on May 1, TEPCO said the amount of water being pumped into the reactor's pressure vessel had been brought back down from 10 to 6 tons per hour. As a result pressure inside the containment vessel rose to 1.4 times normal atmospheric pressure -- **about the same level as before the amount of water was increased.**

Officials said the water level inside the reactor's pressure vessel remained almost unchanged -- at about 1.6 meters above the top of the fuel rods -- when the amount of water was temporarily increased. With water pumped into the pressure vessel leaking out, workers estimate that the water level inside the containment vessel stands at about 6 meters, but they do not know the exact level.

More than 7,400 tons of water -- roughly the amount needed to fill the containment vessel -- has already been pumped into the reactor. Normally, this would have significantly increased the water level inside the pressure vessel.

"We don't know why the water level isn't increasing," a TEPCO representative said. "We've judged that 6 tons of water per hour is enough to cool the reactor down, so we want to continue to pump in water this way."

On May 1 TEPCO announced that it had pumped about 120 tons of water from the turbine building of the No. 6 reactor into a makeshift tank. The level of accumulated water, totaling roughly 4,900 tons, stands at about 2 meters. Its level of radioactivity is thought to be relatively low. Makeshift tanks will be used to store the remaining water.

Une nouvelle digue protégera Fukushima

LEMONDE.FR avec AFP | 02.05.11 | 08h25

Vue aérienne de la centrale de Fukushima, le 20 mars 2011.AFP/AIR PHOTO SERVICE

Une nouvelle digue va être construite devant la centrale nucléaire endommagée de Fukushima Dai-Ichi, sur la côte nord-est du Japon, afin de la protéger contre d'éventuels tsunamis de grande ampleur, a annoncé l'opérateur Tokyo Electric Power.

Construite sur un terrain situé dix mètres au-dessus du niveau de la mer, cette nouvelle digue de deux mètres de haut et de 500 mètres de long devrait être achevée d'ici à mi-juin, selon l'opérateur, cité par des médias locaux.

Selon le journal *Daily Yomiuri*, le groupe japonais a pris cette décision sur la base des travaux d'une équipe de chercheurs qui ont effectué des simulations sur les possibles répliques du séisme et envisagent des vagues pouvant aller jusqu'à 7 mètres.

Le tremblement de terre du 11 mars, de magnitude 9, a provoqué le déferlement d'une vague d'environ 14 mètres sur la centrale. Ce tsunami a entraîné une panne des circuits de refroidissement de la centrale nucléaire Fukushima 1, entraînant des explosions d'hydrogène et d'importantes fuites radioactives.

Tepco a également annoncé son intention de faire passer de 1 000 à 3 000 le nombre de personnes – salariés directs ou employés de sous-traitants – pouvant travailler sur le site endommagé afin de limiter leurs temps d'exposition aux radiations. La limite légale de radiations autorisées pour les hommes travaillant dans le nucléaire en temps de crise a été relevée à 250 millisieverts par an depuis l'accident de Fukushima, contre 100 auparavant.

Tepco estime qu'il faudra trois mois pour que le niveau de radiations commence à baisser et encore trois à six mois supplémentaires pour réduire les fuites radioactives à un niveau *"très bas"*.

Une fuite radioactive décelée à la centrale de Tsuruga au Japon

LEMONDE.FR avec AFP | 02.05.11 | 13h40

Vue aérienne de la centrale de Tsuruga, en mars 2010.REUTERS/KYODO

Une augmentation des niveaux de radioactivité a été constatée dans l'eau de refroidissement d'un réacteur à la centrale de Tsuruga, à quelque 350 kilomètres à l'ouest de Tokyo, indique Japan Atomic Power, l'exploitant de l'installation.

Il n'y a aucun impact radioactif sur l'environnement extérieur, a assuré dans un communiqué la société. Les opérateurs de sites nucléaires japonais redoublent de vigilance depuis l'accident majeur survenu à la centrale de Fukushima, à la suite du tremblement de terre et du tsunami du 11 mars.

Au cours d'un contrôle régulier effectué lundi à Tsuruga, les techniciens ont relevé une augmentation de la densité d'éléments radioactifs (xénon 133 et iode 133) dans l'eau de refroidissement du circuit primaire de l'un des deux réacteurs du site, selon le communiqué. *"Nous pensons qu'il pourrait provenir de l'assemblage de combustible et avons renforcé la surveillance de la densité de substances radiatives dans le liquide de refroidissement primaire"*, est-il précisé. La société envisage d'arrêter le réacteur pour des examens plus approfondis.

Radiation leaks from fuel rods suspected at Tsuruga plant

FUKUI, Japan, May 2, Kyodo

Leaks of radioactive substances from fuel rods are suspected to have occurred at a nuclear power plant in Tsuruga, the Fukui prefectural government said Monday, citing a rise in the level of radioactive substances in coolant water.

The operator, Japan Atomic Power Co., will manually shut down the No. 2 reactor of the plant on the Sea of Japan coast and examine the primary cooling system for it. The local government denied that the levels of radioactive substances could threaten the nearby environment.

According to Japan Atomic, 4.2 becquerels of iodine-133 and 3,900 becquerels of xenon gas were detected per cubic centimeter Monday, up from 2.1 and 5.2 becquerels, respectively, during previous measurements conducted last Tuesday.

Radiation leaks from fuel rods suspected at Tsuruga plant

Leaks of radioactive substances from fuel rods are suspected to have occurred at a nuclear power plant in Tsuruga, the Fukui prefectural government said Monday, citing a rise in the level of radioactive substances in coolant water.

The operator, Japan Atomic Power Co., will manually shut down the No. 2 reactor of the plant on the Sea of Japan coast and examine the primary cooling system for it. The local government denied that the levels of radioactive substances could threaten the nearby environment.

According to Japan Atomic, 4.2 becquerels of iodine-133 and 3,900 becquerels of xenon gas were detected per cubic centimeter Monday, up from 2.1 and 5.2 becquerels, respectively, during previous measurements conducted last Tuesday.

It is possible that a pinhole has been created in a zirconium alloy encasing fuel pellets, according to sources at Japan Atomic.

The company said the planned shutdown is a precaution following the crisis at the Fukushima Daiichi power station caused by the March 11 earthquake and tsunami. Japan Atomic's regulations require a reactor to be halted when the amount of leaked iodine reaches 40,000 becquerels.

The company said it will increase the frequency of measurements to once a day from once a week before deciding when to shut down the reactor.

URGENT: Seabed radiation 100-1,000 times normal level off Fukushima plant: TEPCO

TOKYO, May 3, Kyodo

Radiation readings have risen to 100-1,000 times the normal level on the Pacific seabed near the crippled Fukushima Daiichi nuclear power plant, the operator said Tuesday.

The high levels of radioactive materials were detected from samples taken Friday from the seabed at points 20-30 meters deep, according to Tokyo Electric Power Co.

TEPCO neglected radiation checks in building where two women absorbed high doses

Tokyo Electric Power Co. (TEPCO) failed to check the levels of radiation inside a key operation center at the crippled Fukushima nuclear power plant before two female workers were exposed to high levels of radiation there.

The two workers have recently been exposed to radiation higher than the legal limit for female workers -- lower than that for men -- of 5 millisieverts over a three-month period. For about two weeks after the March 11 earthquake, the utility did not check the radiation levels inside a special quake-resistant building where the two workers were exposed. About 200 workers use the building on the premises of the Fukushima No. 1 Nuclear Power Plant each day as a base to deal with the ongoing crisis.

The building was opened for use in July 2010 as an emergency response base. Located about 200 meters northwest of the No. 1 nuclear reactor, it was built to withstand earthquakes measuring the strongest quakes on the Japanese seven-point scale. However, its structure allows small amounts of radiation to leak through vents. When designing the power plant, the utility had not envisaged the hydrogen explosion that actually damaged the doors of the building and permitted radioactive substances to flow in inside.

TEPCO said the delay in preparing a "buffer area" where workers were supposed to take off their protective gear was a factor behind its failure to prevent radioactive substances from coming into the building. One of the women in her 50s suffered internal radiation exposure of 13.6 millisieverts (and external exposure of 3.95 millisieverts), while another woman in her 40s had internal exposure of 6.71 millisieverts (and external exposure of 0.78 millisieverts) -- numbers which suggest most of their exposure came from what they inhaled in the building.

TEPCO said it had been aware that the levels of radiation inside the building were high. But it then said, "We initially thought that way because the levels of radiation outside the building were high." TEPCO started checking the levels of radiation in the building on March 24 -- a day after it stopped female workers from working there.

Since then, TEPCO has taken steps such as setting up small rooms equipped with air cleaners at entrances and putting lead sheets over the windows to shut out radiation. TEPCO has also been checking male workers on their internal radiation exposure. Male workers are allowed to be exposed to up to 250 millisieverts of radiation per year.

"We should've had workers wear masks earlier. I believe the fact that radioactive substances entered the building after the hydrogen explosion will be an important lesson for us. We want to assess the way

TEPCO handled the situation as quickly as possible," said Hidehiko Nishiyama, a spokesman for the Nuclear and Industrial Safety Agency.

Site REGARD SUR LA PECHE ET L'AQUACULTURE

"Plus de la moitié de la production halieutique japonaise est sous la menace de la contamination radioactive de la centrale de Fukushima-Daiichi. (cliquer sur la carte pour agrandir)

En janvier 2011, les pêcheurs et les aquaculteurs de la région de Tohoku se préparaient à recevoir des indemnités financières après les dégâts du tsunami 2010 (suite au séisme chilien du 28 février). Une année plus tard, l'énorme tsunami du 11 mars 2011 allait tout balayer, installations aquacoles, bateaux de pêche, infrastructures portuaires...

Quelques jours après, la radioactivité menacerait définitivement la survie de centaines de communautés de pêcheurs sur toute la côte nord-est du Japon, la plus riche en ressources halieutiques de l'archipel....

La centrale nucléaire de Fukushima, endommagée par le séisme du 11 mars 2011 puis submergée par le tsunami, rejette ses eaux irradiées directement en mer. Selon l'Agence de sûreté nucléaire japonaise, la radioactivité monte en flèche dans les eaux à proximité de la centrale de Fukushima-Daiichi. L'augmentation très importante de cette pollution atomique fait craindre une réaction en chaîne dans l'ensemble des écosystèmes marins au nord-est du Japon, jusqu'à Hokkaido.

15 avril 2011 : Courants marins et température de l'eau de mer

Source : Institut océanographique du Japon

Selon les statistiques du ministère de l'agriculture et de la pêche japonais, la zone littorale comprise entre les départements de Kanto et d'Hokkaido concentre plus de la moitié de la production de la pêche et de l'aquaculture du pays avec une production annuelle de près de 3 millions de tonnes (500.000 tonnes en aquaculture + 2.500.000 tonnes à la pêche

"Pour aller plus loin....

Le courant chaud de Kuroshio (l'équivalent de notre Gulf Stream en atlantique) longe la côte sud-est du Japon. Depuis début avril, il a tendance à monter plus au nord avant d'obliquer vers l'est direction océan Pacifique... Toutefois, les courants marins restent toujours très faibles sur le littoral proche de la centrale de Fukushima Daiichi. Les éléments radio-actifs rejetés en mer par la centrale restent donc concentrés sur la bordure côtière... Ce

qui explique la forte contamination de certaines espèces marines et l'interdiction de pêche dans un rayon de 30 km autour de la centrale. Le lançon qui concentre l'iode et le césium radioactifs (plus que les autres espèces pour des raisons non expliquées) est interdit de pêche dans tout le département d'Ibaraki au sud de Fukushima."

Ce schéma du ministère de la pêche japonais explique que le poisson n'accumule pas les radionucléides, mais qu'il les excrète

original japonais : http://www.jfa.maff.go.jp/j/kakou/Q_A/pdf/110331_2suisan.pdf

Alors que les scientifiques du monde entier se posent des questions sur les incidences des déversements d'eaux radioactives de la centrale de Fukushima Daiichi à l'encontre des écosystèmes marins et notamment sur « l'empoisonnement » des produits de la mer, et qu'ils constatent un manque criant d'études sur le sujet, l'administration japonaise évacue le problème en expliquant que les poissons n'accumulent pas les éléments radioactifs comme le césium !"

COMMUNIQUE DE PRESSE DU 13 AVRIL 2011

POUR LE GOUVERNEMENT, L'EXPOSITION AUX RAYONNEMENTS IONISANTS

N'EST PLUS CANCEROGENE !

FARCE DE TRES MAUVAIS GOUT

SURREALISTE : En plein débat sur les risques liés au Nucléaire après la catastrophe de FUKUSHIMA, le gouvernement vient de retirer du décret « Pénibilité » l'exposition aux rayonnements ionisants de la liste des risques, ouvrant droit à une possibilité de départ en retraite anticipée pour les travailleurs exposés.

Pourtant, lors de la consultation pour avis de la Commission Accident du Travail – Maladies Professionnelles de la Sécurité sociale le 23 février dernier, cette exposition figurait bien dans la liste des facteurs de pénibilité susceptibles d'ouvrir droit à un départ anticipé en retraite pour les travailleurs concernés.

Ainsi, en conséquence, les travailleurs du Nucléaire sont mis à l'écart d'une disposition valable pour toutes les expositions professionnelles à des cancérogènes alors que leur risque de développer un cancer est supérieur au risque encouru par ceux qui sont exposés à d'autres cancérogènes dans le cadre de leur travail.

EN EFFET : Toutes les données épidémiologiques montrent que l'exposition aux rayonnements ionisants, respectant les limites des normes professionnelles, présente des risques de cancer et de leucémies supérieurs à ceux que représente l'exposition aux autres substances cancérogènes, prises elles aussi dans les limites des normes d'expositions professionnelles.

Par exemple, un travailleur soumis annuellement à la « dose maximale admissible » (20mSv/an) présentera à l'issue de sa carrière un risque de cancer dix fois supérieur à celui d'un travailleur exposé à l'amiante dans les mêmes limites réglementaires.

Ecarter les travailleurs du Nucléaire des dispositions en faveur de la pénibilité alors que les risques qu'ils encourent en matière de cancers sont encore plus grands que dans les autres industries, est un non sens social, une injustice flagrante.

Il ne peut être que la conséquence d'un formidable lobbying exercé par les industriels du Nucléaire au moment même où le monde entier s'interroge sur la santé de ces travailleurs qui interviennent actuellement sur le Site de FUKUSHIMA.

320.000 salariés en France sont exposés aux rayonnements ionisants dans le cadre de leur activité professionnelle. Les salariés du Nucléaire représentent 47% de la population ayant pris une dose supérieure à 1 mSV alors qu'ils ne représentent « que » 20% des salariés exposés. Parmi eux, ce sont en particulier les sous-traitants qui enregistrent 80% de la totalité des doses prises et qui sont soumis aux plus fortes expositions.

LA CGT EXIGE DU GOUVERNEMENT QU'IL REINTEGRE DANS CE DECRET L'EXPOSITION AUX RAYONNEMENTS IONISANTS TEL QUE CELA ETAIT PREVU DANS LE PROJET DE DECRET SOUMIS AUX PARTENAIRES SOCIAUX.

EXPLICATIONS :

Les dernières données épidémiologiques fournies par l'INSERM (janvier 2010) sur les sous-traitants indiquent que l'excès de risque relatif¹ (ERR) est de 1,54 pour les salariés ayant reçu une dose de 100 mSV alors qu'il est de 1,35 dans les industries chimiques ou 1,25 dans le BTP pour toute la carrière professionnelle².

Or, à la fin de leur carrière professionnelle, les sous-traitants du Nucléaire peuvent facilement atteindre les 400 ou 500 mSV !

Ils peuvent même aller jusqu'à 800 mSV (20 mSV/an pendant 40 ans) puisque c'est là le « risque acceptable ». Selon les données épidémiologiques du CIRC³ (sur 407.000 travailleurs du Nucléaire dans 15 pays), le risque à cette dose cumulée carrière serait alors de 12% de surmortalité par rapport à une population non exposée. C'est 2 fois supérieur au risque que la CIPR⁴ avait calculé à partir des survivants d'Hiroshima.

¹ Facteur par lequel le risque de maladie est multiplié en fonction d'une exposition spécifique. C'est le risque supplémentaire dû à une exposition par rapport au risque d'une population non exposée.

² Ellen IMBERNON, cancers professionnels : vers une meilleure connaissance, rapport INVS/2009

³ Cardis, E., et al., 2005

⁴ Commission internationale de protection contre les rayonnements, préconisations CIPR 60 adoptée par l'AIEA en 1990.

Les trois catégories les plus exposées sont : le médical 62%, l'industrie (non nucléaire) 10,5% et le Nucléaire 20% (industriel et armement). Le reste est le secteur de la recherche et les transports aériens

*Les activités médicales représentent 19,6% de la dosimétrie collective, l'industrie non nucléaire 18,2%, le **Nucléaire représente 26,1%.***

*Mais si l'on ne regarde que ceux qui ont pris une dose supérieure à 1 mSV, alors **les salariés du Nucléaire représentent 47% de la population ayant pris une dose supérieure à 1 mSV (alors qu'ils ne représentent « que » 20% des salariés exposés)***

*Et dans le Nucléaire: **6,3% des sous-traitants ont pris une dose supérieure à 6 mSV** ; ils sont 0,4% chez les agents EDF et 0,7% dans le secteur médical.*

Tsunamis sur les côtes de France ,see :

<http://www.lefigaro.fr/sciences/2011/04/06/01008-20110406ARTFIG00691-depuis-1700-34-tsunamis-sur-les-cotes-francaises.php>

TEPCO compensation means higher electric bills

2011/05/04 <http://www.asahi.com/english/TKY201105030093.html>

Tokyo Electric Power Co. employees bow in apology on May 2 to Fukushima Prefecture residents who were relocated to Iida, Nagano Prefecture, following the Fukushima No. 1 nuclear power plant accident. (Tadayuki Ito)

Consumers can expect to see higher electric bills as Tokyo Electric Power Co. passes on its compensation obligations due to the Fukushima No. 1 nuclear power plant accident.

Government sources said May 2 that an estimate of the total amount of compensation required reached 4 trillion yen (**\$48.7 billion**) and that **TEPCO would be expected to cover about half of that.**

TEPCO and the eight other electric power companies will pay the compensation over a 10-year period, and each company is expected to raise electricity rates. For TEPCO, that would likely mean a close to **20-percent increase in rates.**

Because the accident at the Fukushima plant is far from resolved and the exact amount needed for compensation and to decommission the crippled nuclear reactors have not been set, the estimates are preliminary figures that would serve as the outer limits and still allow TEPCO to continue as an independent company.

While consumers and taxpayers will be forced to share the TEPCO burden, the major financial institutions that have made emergency loans to the electric power company would not be expected to pay more. That will likely lead to questions about the fairness of the compensation plan.

Cabinet ministers handling the issue are continuing with discussions, but under the estimates that have been calculated, TEPCO would handle the compensation.

Whatever funds it cannot procure will have to be provided by a new organization to be established by the electric power companies. The central government will also contribute funds to that new organization. The electric power companies will be asked to repay the public funds by returning 400 billion yen a year over a 10-year period.

Of that 400 billion yen, TEPCO would be required to make a special contribution of 100 billion yen a year. The remaining 300 billion yen would be shouldered by the nine electric power companies, including TEPCO, that operate nuclear power plants.

Each company's share would be determined by its electric supply. Because TEPCO provides about one-third of all electricity in Japan, its share would be about 100 billion yen.

According to sources, TEPCO will likely have to raise electricity rates by about 16 percent to secure the funds to place in the compensation pool.

The eight other electric power companies would together have to contribute about 200 billion yen. That would mean about a 2-percent increase in electricity rates for those companies.

TEPCO would end up contributing about 2 trillion yen of the overall expected compensation amount, with the eight other electric power companies contributing the remaining 2 trillion yen.

The new organization would receive the equivalent of 1.6 trillion yen in preferred shares in TEPCO as a means of preventing a loss of trust in TEPCO and a downgrading of its debt ratings.

The government estimate also foresees a total cost of 1.5 trillion yen to decommission the six reactors at the Fukushima No. 1 plant as well as an additional 1 trillion yen a year to pay for fuel to be used at thermal power plants.

TEPCO will also be expected to implement downsizing measures totaling 150 billion yen by the next fiscal year as well as selling off a total of 300 billion yen in real estate and stock holdings.

The government expects an annual payment of 1 trillion yen in compensation, with payments to end after four years.

While Chief Cabinet Secretary Yukio Edano rejected the notion of setting an upper limit to the compensation amount to be paid by TEPCO, an estimate for compensation amounts was made to allow TEPCO to compile its financial statements for the fiscal year that ended in March.

Government sources have not given any indication of what would happen if total compensation exceeded 4 trillion yen.

TEPCO is expected to post a net loss of about 800 billion yen for the fiscal year that ended in March. However, the company is seeking to climb out of the red in four years. TEPCO officials want to resume issuing corporate bonds after fiscal 2014 as well as seek to resume dividend payments to shareholders by fiscal 2018.

Workers to enter No. 1 reactor building for 1st time since accident

TOKYO, May 5, Kyodo

Workers will enter the No. 1 nuclear reactor building at the Fukushima Daiichi power plant Thursday for the first time since the complex was damaged by the March 11 mega earthquake and subsequent tsunami, as part of efforts to install a cooling system at the No. 1 reactor, Tokyo Electric Power Co. officials said.

Tokyo Electric, or TEPCO, seeks to remove air contaminated with radioactive substances from inside the reactor building by connecting it to a ventilating device installed at the adjacent turbine building.

Twelve workers with protective suits, masks and air packs will operate for about 40 minutes within the reactor building to connect it to the ventilator with eight pipes, according to the officials.

Workers enter No. 1 reactor building for 1st time since explosion

In this photo released by Nuclear and Industrial Safety Agency, Tokyo Electric Power Co. workers collect data in the control room for Unit 1 and Unit 2 at the tsunami-crippled Fukushima No. 1 Nuclear Power Plant in Okumamachi, Fukushima Prefecture, on March 23, 2011. (AP)

TOKYO (Kyodo) -- Workers entered the No. 1 nuclear reactor building at the Fukushima Daiichi power plant Thursday for the first time since a hydrogen explosion occurred outside the reactor container on March 12, a day after the complex was damaged by a massive earthquake and subsequent tsunami, Tokyo Electric Power Co. officials said.

The workers installed eight pipes of 30 centimeters in diameter connected to a ventilating device at the adjacent turbine building as part of efforts to reduce the high level of radioactive contamination inside the reactor building by circulating air through a filter on the device, the officials said.

The move is aimed at preventing workers from suffering internal radiation exposure when they work on setting up a new cooling system at the No. 1 reactor, according to Tokyo Electric, or TEPCO, which operates the plant in Fukushima Prefecture.

The ventilation, which will be continued for about three days, could pave the way for more workers to enter the reactor building and install heat-exchanger equipment and other devices in an effective manner, the officials said.

They added that the operator is planning to start setting up the cooling system as early as Sunday and begin circulating water in the reactor container next month.

On Thursday, nine workers with protective suits, masks and air packs broke up into several teams to install the pipes, while four others checked radiation levels inside the No. 1 reactor building to make sure the workers were not heavily exposed to radioactive substances, according to the officials.

In this March 23, 2011 file photo released by Nuclear and Industrial Safety Agency, Tokyo Electric Power Co. workers collect data in the control room for Unit 1 and Unit 2 at the tsunami-crippled Fukushima Dai-ichi nuclear power plant in Okumamachi, Fukushima Prefecture, Japan. (AP Photo/Nuclear and Industrial Safety Agency)

The radiation level was 10 to 93 millisieverts per hour inside the reactor building, and the workers were exposed to between 0.24 and 2.8 millisieverts, which was within the expected range, they said.

The task is expected to help reduce the concentration of radioactive substances inside the building to one-twentieth the current levels as the air will go through the pipes and through the filter, which will catch the substances, before going back to the reactor building.

The utility also said it wants to install the new cooling system at the No. 2 and No. 3 reactors, where the original cooling functions have also been lost, but it does not yet know when it can do so.

As the spread of high levels of radioactive substances has forced residents in nearby municipalities to evacuate for an indefinite period, Prime Minister Naoto Kan said the same day the government will judge early next year if the evacuees could return home.

"We will be able to see a certain stable condition early next year if the restoration work goes as scheduled," Kan said during a meeting with the mayor of Futaba, one of the affected municipalities. TEPCO forecasts it may stabilize the damaged reactors in about six to nine months.

"At that point, we will determine if the evacuating people could return home by taking monitoring results into consideration," Kan said during the meeting in Kazo, Saitama Prefecture, where some people from Futaba are being housed in shelters.

In Fukushima Prefecture, TEPCO President Masataka Shimizu toured some municipalities and apologized to residents and local government officials for the crisis at the plant.

In this March 20, 2011 aerial file photo taken by a small unmanned drone and released by Air Photo Service, the crippled Fukushima No. 1 Nuclear Power Plant is seen in Okumamachi, Fukushima prefecture. From top to bottom: Unit 1, Unit 2, Unit 3 and Unit 4. (AP Photo/Air Photo Service)

At a shelter in Nihonmatsu, Shimizu knelt down in front of about 150 evacuees, saying, "I apologize from deep in my heart. We'll do our utmost so you can go back to your hometowns."

Resistance from Regulators

Nuclear Stress Tests May Be Watered Dow

05/04/2011 <http://www.spiegel.de/international/europe/0,1518,760654,00.html>

In the wake of Fukushima, EU officials pledged to create stress tests for nuclear power plants that would evaluate the threat posed by natural disasters, terrorism, cyberwar and human error. Now a major German newspaper is reporting that regulators are unwilling to accept stricter scrutiny and the plans are likely to get watered down.

After Japan's nuclear disaster at Fukushima, the European Union announced with great fanfare that it would introduce stress tests for Europe's nuclear power plants to help ensure that a similar catastrophe could not happen here. It appears, however, that the final plans will be far less ambitious than originally envisioned.

Germany's *Süddeutsche Zeitung* newspaper is reporting that the Western European Nuclear Regulators' Association has completed its proposal for the tests. Under the final plan, however, the plants would only be required to undergo stress test inspections for dangers presented by natural disasters like earthquakes, tsunamis or extreme fluctuations in weather.

At the end of March, leaders of the 27 EU member states agreed at a summit that inspection measures at the 146 nuclear plants within the bloc would be stepped up to include additional accident scenarios. Additional tests would be conducted to consider electricity supplies like those that failed at Fukushima, cooling systems and additional aspects like terrorist attacks, human error or the plants' ability to function safely during unexpected emergency situations. In an interview with SPIEGEL in April, European Union Energy Commissioner Günther Oettinger of Germany said: "We will also run simulations of a terrorist attack with an airplane and a cyber attack on the computer system."

'The Question Is Open'

But Western European nuclear regulators are now staunchly rejecting those calls, *Süddeutsche Zeitung* reported in its Wednesday edition. **The regulators reportedly stated in an internal paper that they would only agree to conduct stress tests involving natural disaster scenarios -- and not terrorist strikes or other manmade situations. Instead, they would agree to compose reports on potential threats that would be submitted to the European Commission in Brussels. Neither would independent nuclear experts be given access to the plants under the plan.**

European energy ministers discussed the issue during an informal meeting on Tuesday and Wednesday in Gödöllő, Hungary. At the end of the meeting, Hungary, which currently holds the six-month rotating presidency of the EU, issued a statement saying that the stress tests would begin in June.

In its report, the *Süddeutsche Zeitung* cited sources indicating that the ministers appear likely to agree to the regulators' plan, and that the nuclear plants would only be tested for possible natural disasters. Countries that want more stringent tests could do so voluntarily, the newspaper quoted a source close to Energy Commissioner Günther Oettinger as saying. On Tuesday, Oettinger said publicly that "the

question is open" as to whether stricter stress test measures would be included, admitting there were differences between the 27 member states.

European Commission sources told the newspaper that France and Britain have led the efforts to oppose more stringent stress tests. With France's 59 plants and Britain's 19, the two operate the largest number of nuclear power plants of any countries in Europe. Government officials in Paris and London have already stated that they plan to rely more heavily on nuclear power in the future despite the Fukushima disaster. Officials in London also stated they would not publish the results of the stress tests, which are expected to be completed by December.

The European Commission still feels that even the watered-down plan is better than the status quo. Even under the more limited plan, officials in Brussels will still get access for the first time to construction plans for plants and they would also be provided with a much better general overview of all European atomic power facilities. EU member states will also be required to disclose the conditions stipulated during the permit approval process for construction and operation. Officials described the development as "major progress." After a few more rounds of consultations, a final plan is expected to be introduced on May 12 in Brussels.

Speaking on Tuesday, International Energy Agency Executive Director Nobuo Tanaka told reporters that some older nuclear power plants in the EU may be forced to close earlier than planned as a result of the stress tests.

Efforts to water down plans for more stringent stress tests have sparked criticism in Germany. "We need to test all disaster scenarios, regardless whether they are caused by man or nature," Angelika Niebler, a German member of the European Parliament with Bavaria's conservative Christian Social Union party, told the *Süddeutsche*. Rebecca Harms, who chairs the party group in the European Parliament for the Greens, spoke of a "dangerous lowering" of expectations in the plans. She said Energy Commissioner Oettinger had broken his pledge to make European nuclear power plants as safe as possible and to develop new, uniform standards.

Concerns about Energy Costs

At the same time, a fresh debate has broken out in Germany over higher prices for electricity in the country. After Fukushima, German Chancellor Angela Merkel reversed her government's decision, taken last year, to delay the nuclear phase-out -- which was passed by former Chancellor Gerhard Schröder in his government with the Greens -- and extend plant lifespans. In March, Merkel shut down Germany's oldest plants and placed a three-month moratorium on the lifespan extensions.

Now German companies from energy-intensive industrial sectors have rung the alarm bell, warning that energy prices could soon skyrocket.

"We already have the highest electricity prices in Europe," Kurt Bock, who will become CEO of chemical maker BASF on Friday, told reporters this week. "Our demand is very clear: We need affordable energy prices in Germany." He also said that energy supply must be guaranteed, without any shortfalls, 24 hours a day. Bock questioned whether it would be possible to ensure supplies and meet climate protection targets for reducing CO2 emissions. "I don't see any way that we can reconcile these two points with an expedited phase-out" of nuclear power, he said.

However, the question of whether a nuclear withdrawal will automatically lead to an increase in prices is disputed. **"We can phase out nuclear energy faster without having an irresponsible rise in energy prices,"** former United Nations environment chief Klaus Töpfer, who is heading Germany's so-called "Ethics Commission" to study the future of nuclear power, told the *Neue Osnabrücker Zeitung* newspaper. He said it would also be possible to do so without putting jobs at risk.

With his statements, Töpfer distanced himself from [Johannes Teyssen](#), who heads the major German power utility E.on. The executive, whose company operates nuclear power plants, had recently warned that Germany would only be able to phase out nuclear energy by importing atomic power and fossil fuel-generated electricity from other countries.

Töpfer said: "The fact that the head of a very large company that operate nuclear power plants is representing a position like that isn't surprising. But I don't think it is true."

Combined gov't and TEPCO news conferences don't appear to be improvement

A scene from a regular joint news conference between government organizations concerned and TEPCO about crisis at the Fukushima No. 1 Nuclear Power Plant in Tokyo on May 4. (Mainichi)

Joint news conferences by government bodies and the Tokyo Electric Power Co. (TEPCO) over the crisis at the tsunami-hit nuclear power plant appear to have been far from effective at promoting the "transparent and accurate information releases" the government said it was aiming for.

The government's joint task force on nuclear accident countermeasures began the joint news conferences last month. The conferences, initially held on a daily basis, are attended by representatives from TEPCO, the Nuclear and Industrial Safety Agency (NISA), the Nuclear Safety Commission (NSC) and the Ministry of Education, Culture, Sports, Science and Technology (MEXT). Each conference lasts for three to five hours.

However, despite the length of the conferences, they are not addressing everything reporters want to know. Goshi Hosono, secretary-general of the government joint task force, has declared that education-related issues will not be covered by the conferences, but reporters' questions for several days nonetheless centered on government set limits on radiation exposure for outdoor activities of

elementary and junior high school students. Currently those activities are restricted when the annual dose of radiation exceeds 20 millisieverts, but this has become a controversial issue.

It was pointed out by reporters that an NSC member who was said to have suggested the upper limit had actually been opposed to it. They sought a disclosure of the details of that matter and asked that the NSC member attend at a later conference.

However, the task force secretariat declined to comply, repeating that the government had gone through the proper procedures in setting the standards and stirring protest from the journalists.

In the end, at a May 2 news conference the secretariat to the task force released a document detailing what led up to the decision on the dose limit.

At a May 4 conference, an irritated-seeming Hosono said, "From now on, we'd like you to ask questions about that issue at the MEXT."

More than 100 pages of documents, such as data on radiation levels in areas near the crippled Fukushima No. 1 Nuclear Power Plant, are distributed to around 200 reporters at each news conference.

Officials who are supposed to answer questions have occasionally been seen dozing off, showing their fatigue.

After the April 28 conference, Hosono notified news organizations that the task force would hold the joint news conferences only every other day during the Golden Week holiday period -- lasting from April 29 to May 5 -- in order to "achieve a balance between (the task force's) primary duties and the news conferences." He also said that some of the organizations represented at the conferences are requesting that the meets be limited to two hours.

As to the reason for holding the joint news conferences, Hosono cited requests from legislators from both ruling and opposition parties and overseas news organizations and said, "Previously, (government organizations and TEPCO) had held separate news conferences, causing information overlaps and confusion."

However, TEPCO and NISA have still been holding their own news conferences on days when the joint conferences have not been held.

Yasuhiko Tajima, professor of news media at Sophia University, criticized the task force for limiting the scope of questions and limiting the length of the news conferences.

"News conferences being long isn't a bad thing if freelance journalists are allowed to attend and it leads to further information disclosure," he said. "Rather, if the task force imposes time limits on the length of the conferences, it will be neglecting its responsibility to explain the situation and infringing on people's right to know."

"The government said it was combining the news conferences to keep consistency in the released information, but that was nothing more than serving its own goals. Excluding important issues like the 20 millisievert per year dose limit for children from the conferences seems to me to be an evasion of responsibility," he said.

Hiroshima A-bomb victim voices anger over handling of nuclear crisis

Atsushi Hoshino gives his views about the nuclear accident at his residence in Fukushima. (Mainichi)

FUKUSHIMA -- Atsushi Hoshino, an 83-year-old A-bomb victim from Hiroshima, harshly criticized the government's handling of the ongoing crisis at the nuclear power plant crippled by the March 11 earthquake and tsunami, calling for a sweeping review of the nation's energy policy and people's ways of life.

Hoshino, a professor emeritus at Fukushima University, told the Mainichi in an interview in his home in Fukushima that he had initially thought that nuclear power generation was different in nature from the blasting of weapons of mass destruction. "But when I actually saw the nuclear reactors getting out of control, I had to change my thinking," he said. Based on his own experience as well as the suffering inflicted on many other victims of the atomic bombings of Hiroshima and Nagasaki, he expressed his anxiety and anger over the way the government has been responding to the nuclear disaster.

When he was a 17-year-old high school student, he saw from his home in Kure, Hiroshima Prefecture, a mushroom cloud fill the sky over the city of Hiroshima. The following day, he walked around the city in search of a friend. Around him were burnt-out ruins, piles of bodies, fires still burning, and foul smells. People were weeping in despair. The Hiroshima Hoshino had known was gone.

Hoshino managed to find his friend, but the friend's nostrils and lips were carbonized and he could not even drink water. Hoshino could do nothing but pick away the maggots coming over his friend and watch him pass away.

He helped in the horrible work of cremating the bodies of Hiroshima citizens, digging large holes in the ground, putting bodies inside, covering them with steel sheets, pouring heavy oil on and setting it ablaze. He did this work again and again. "The bodies looked awful. You couldn't tell whether they were male and female. They didn't even have a fraction of dignity left in them," Hoshino said.

After the war he got cataracts and rectal cancer -- aftereffects of exposure to radiation from the atomic bombing. He currently serves as secretary-general of a group in Fukushima Prefecture that supports the

A-bomb victims. He is now worried about the welfare of several of his group's members who lived near the nuclear power plant. The group has about 90 members and hasn't been able to get in touch with over 10 of its members who lived near the nuclear power plant.

"I am very upset with Tokyo Electric Power Co., the government, and the Nuclear and Industrial Safety Agency. Their safety management, including their post-accident response, has been unbelievably lax. I don't sense an enthusiasm from them to work hard to protect people's lives," he said. "Based on the lessons we learn from this nuclear accident, I think we have to review the energy policy and our way of life."

Resistance from Regulators

Nuclear Stress Tests May Be Watered Dow

05/04/2011 <http://www.spiegel.de/international/europe/0,1518,760654,00.html>

In the wake of Fukushima, EU officials pledged to create stress tests for nuclear power plants that would evaluate the threat posed by natural disasters, terrorism, cyberwar and human error. Now a major German newspaper is reporting that regulators are unwilling to accept stricter scrutiny and the plans are likely to get watered down.

After Japan's nuclear disaster at Fukushima, the European Union announced with great fanfare that it would introduce stress tests for Europe's nuclear power plants to help ensure that a similar catastrophe could not happen here. It appears, however, that the final plans will be far less ambitious than originally envisioned.

Germany's *Süddeutsche Zeitung* newspaper is reporting that the Western European Nuclear Regulators' Association has completed its proposal for the tests. Under the final plan, however, the plants would only be required to undergo stress test inspections for dangers presented by natural disasters like earthquakes, tsunamis or extreme fluctuations in weather.

At the end of March, leaders of the 27 EU member states agreed at a summit that inspection measures at the 146 nuclear plants within the bloc would be stepped up to include additional accident scenarios. Additional tests would be conducted to consider electricity supplies like those that failed at Fukushima, cooling systems and additional aspects like terrorist attacks, human error or the plants' ability to function safely during unexpected emergency situations. In an interview with SPIEGEL in April, European Union Energy Commissioner Günther Oettinger of Germany said: "We will also run simulations of a terrorist attack with an airplane and a cyber attack on the computer system."

'The Question Is Open'

But Western European nuclear regulators are now staunchly rejecting those calls, *Süddeutsche Zeitung* reported in its Wednesday edition. **The regulators reportedly stated in an internal paper that they would only agree to conduct stress tests involving natural disaster scenarios -- and not terrorist strikes or other manmade situations. Instead, they would agree to compose reports on potential threats that would be submitted to the European Commission in Brussels. Neither would independent nuclear experts be given access to the plants under the plan.**

European energy ministers discussed the issue during an informal meeting on Tuesday and Wednesday in Gödöllő, Hungary. At the end of the meeting, Hungary, which currently holds the six-month rotating presidency of the EU, issued a statement saying that the stress tests would begin in June.

In its report, the *Süddeutsche Zeitung* cited sources indicating that the ministers appear likely to agree to the regulators' plan, and that the nuclear plants would only be tested for possible natural disasters. Countries that want more stringent tests could do so voluntarily, the newspaper quoted a source close to Energy Commissioner Günther Oettinger as saying. On Tuesday, Oettinger said publicly that "the question is open" as to whether stricter stress test measures would be included, admitting there were differences between the 27 member states.

European Commission sources told the newspaper that France and Britain have led the efforts to oppose more stringent stress tests. With France's 59 plants and Britain's 19, the two operate the largest number of nuclear power plants of any countries in Europe. Government officials in Paris and London have already stated that they plan to rely more heavily on nuclear power in the future despite the Fukushima disaster. Officials in London also stated they would not publish the results of the stress tests, which are expected to be completed by December.

The European Commission still feels that even the watered-down plan is better than the status quo. Even under the more limited plan, officials in Brussels will still get access for the first time to construction plans for plants and they would also be provided with a much better general overview of all European atomic power facilities. EU member states will also be required to disclose the conditions stipulated during the permit approval process for construction and operation. Officials described the development as "major progress." After a few more rounds of consultations, a final plan is expected to be introduced on May 12 in Brussels.

Speaking on Tuesday, International Energy Agency Executive Director Nobuo Tanaka told reporters that some older nuclear power plants in the EU may be forced to close earlier than planned as a result of the stress tests.

Efforts to water down plans for more stringent stress tests have sparked criticism in Germany. "We need to test all disaster scenarios, regardless whether they are caused by man or nature," Angelika Niebler, a German member of the European Parliament with Bavaria's conservative Christian Social Union party, told the *Süddeutsche*. Rebecca Harms, who chairs the party group in the European Parliament for the Greens, spoke of a "dangerous lowering" of expectations in the plans. She said Energy Commissioner Oettinger had broken his pledge to make European nuclear power plants as safe as possible and to develop new, uniform standards.

Concerns about Energy Costs

At the same time, a fresh debate has broken out in Germany over higher prices for electricity in the country. After Fukushima, German Chancellor Angela Merkel reversed her government's decision, taken last year, to delay the nuclear phase-out -- which was passed by former Chancellor Gerhard Schröder in his government with the Greens -- and extend plant lifespans. In March, Merkel shut down Germany's oldest plants and placed a three-month moratorium on the lifespan extensions.

Now German companies from energy-intensive industrial sectors have rung the alarm bell, warning that energy prices could soon skyrocket.

"We already have the highest electricity prices in Europe," Kurt Bock, who will become CEO of chemical maker BASF on Friday, told reporters this week. "Our demand is very clear: We need affordable energy prices in Germany." He also said that energy supply must be guaranteed, without any shortfalls, 24 hours a day. Bock questioned whether it would be possible to ensure supplies and meet climate protection targets for reducing CO2 emissions. "I don't see any way that we can reconcile these two points with an expedited phase-out" of nuclear power, he said.

However, the question of whether a nuclear withdrawal will automatically lead to an increase in prices is disputed. **"We can phase out nuclear energy faster without having an irresponsible rise in energy prices,"** former United Nations environment chief Klaus Töpfer, who is heading Germany's so-called "Ethics Commission" to study the future of nuclear power, told the *Neue Osnabrücker Zeitung* newspaper. He said it would also be possible to do so without putting jobs at risk.

With his statements, Töpfer distanced himself from [Johannes Teyssen](#), who heads the major German power utility E.on. The executive, whose company operates nuclear power plants, had recently warned that Germany would only be able to phase out nuclear energy by importing atomic power and fossil fuel-generated electricity from other countries.

Töpfer said: "The fact that the head of a very large company that operate nuclear power plants is representing a position like that isn't surprising. But I don't think it is true."

TEPCO starts flooding No. 1 reactor with water for cooling system

TOKYO, May 6, Kyodo

The operator of the crisis-hit Fukushima Daiichi nuclear power plant on Friday started increasing the amount of water being injected into the No. 1 reactor in an effort to stably cool the damaged nuclear fuel inside.

Tokyo Electric Power Co. plans to fill the reactor's primary containment vessel with water to a level above the fuel over the next 20 days or so, and start operating by June an air-cooling device aimed at reducing the temperature of water circulating around the reactor, company officials said.

Restoring the cooling systems of the plant's reactors, which were lost in the wake of the March 11 quake and tsunami, is seen as vital to end the country's worst nuclear crisis, as the current emergency measure of continually injecting water from outside has created vast pools of highly radioactive water within the plant.

Valve at Kashiwazaki-Kariwa nuke plant not working properly: TEPCO

NIIGATA, Japan, May 6, Kyodo

Tokyo Electric Power Co. said Friday it has found an abnormality in one of the valves at the Kashiwazaki-Kariwa nuclear power plant in Niigata Prefecture used to pump cool water to reactors in the event of an emergency.

There is unlikely to be a leakage of radioactive substances or any other impact on the outside environment, the firm known as TEPCO said, adding that it is looking into the cause of the dysfunction.

The utility found during checks of electric-operated valves in the residual heat removal system at the plant's No. 1 reactor Thursday evening that one of the valves did not close properly, and had to close it manually.

Radioactive materials from Fukushima to reach U.S. within few yrs: IAEA

VIENNA, May 6, Kyodo

The International Atomic Energy Agency said Thursday radioactive substances leaked into the Pacific Ocean from the crippled Fukushima Daiichi nuclear plant in Japan are expected to reach the west coast of the United States and Canada within one or two years.

The quantity of the substances, however, is expected to be too small to affect human health, an IAEA official said at a press conference.

Radioactive substances have also been emitted into the atmosphere from the nuclear plant, which was crippled by the March 11 massive earthquake and tsunami, and the leakage was confirmed across the Northern Hemisphere and parts of the Southern Hemisphere.

Industry minister questions safety measures at Hamaoka nuclear plant

OMAEZAKI, Shizuoka -- Economy, Trade and Industry Minister Banri Kaieda expressed concerns over safety measures at the Hamaoka Nuclear Power Plant in Shizuoka Prefecture after inspecting the facility on May 5.

Kaieda visited the controversial plant -- **located at the predicted epicenter of a great Tokai earthquake that experts have been warning of for years** -- to confirm if emergency safety measures required by the government following the accident at the Fukushima No. 1 Nuclear Power Plant had been implemented.

"I raised some questions over issues including (quake and tsunami) drills," Kaieda told reporters following his inspection of the plant in Omaezaki, Shizuoka Prefecture, on May 5, suggesting that anti-disaster measures at the facility are insufficient.

Kaieda said the government would release an assessment of the plant's safety measures in early May, based on the results of his inspection and local opinions.

During his visit, the industry minister inspected power generators that were newly installed by the plant's operator, Chubu Electric Power Co., and a sand dune where a breakwater wall over 15 meters high is scheduled to be built to prevent potential tsunami damage. Following the inspection, Kaieda met Shizuoka Gov. Heita Kawakatsu and Omaezaki Mayor Shigeo Ishihara.

Regarding plans to restart the plant's No. 3 reactor, Kawakatsu expressed reservations, saying, "The plant's tsunami countermeasures are impromptu and extremely insufficient." Ishihara, meanwhile, called on the central government to provide safety guidelines for anti-tsunami measures. He did not clarify his stance on whether the No. 3 reactor should be restarted.

After the meeting, Kaieda commented, "It seems it will take a little more time to implement anti-tsunami measures." He added that he would take the issue of whether to resume operation of the No. 3 reactor seriously.

Meanwhile, Chubu Electric Power Co. President Akihisa Mizuno said the company would respect local opinions, saying, "We don't think we can resume operation immediately after the government releases its assessment. We will move forward only after making credible explanations to the local community and gaining its approval."

Gov't to ask Chubu Electric to stop Hamaoka nuclear power plant

The Hamaoka nuclear power station in Omaezaki, Shizuoka Prefecture, is pictured in this aerial photo taken from a Mainichi helicopter on Feb. 23, 2011. (Mainichi)

TOKYO (Kyodo) -- Prime Minister Naoto Kan said Friday the Japanese government has asked Chubu Electric Power Co. to suspend all its nuclear reactors at the Hamaoka nuclear power station, citing experts' forecast of a major earthquake that could hit the region.

Kan said during an evening news conference, "It's a decision made after thinking about people's safety."

Kan said the nuclear power station lacks medium- to long-term measures for protection against disasters, such as embankments.

The government will take utmost measures not to cause a major imbalance in power demand and supply in Chubu Electric Power's service areas in the event the Hamaoka plant is shut down.

Opinion split on health effects of low radiation doses

As the Fukushima nuclear crisis drags on, so too do abnormally high airborne radiation levels in a number of prefectures, as well as the presence of radioactive materials in water and vegetables.

In response, the government has repeatedly told the public that there is "no immediate health risk" from the contamination, while many experts have chimed in with reassurances that no one need worry if their accumulated dose does not exceed 100 millisieverts. However, how well known are the effects of exposure up to the 100 millisievert line, what experts term a "low dose"?

Radiation damages cells and the DNA in their nuclei. A 1,000 millisievert dose can cause severe symptoms such as hair loss, infertility and even death. Smaller doses don't in general produce such

acute effects, but symptoms can emerge years or even decades after exposure, and create serious worries of passing on genetic abnormalities to subsequent generations.

A follow-up survey of some 93,000 Hiroshima and Nagasaki atomic bombing survivors spanning a period of more than 50 years after the attacks showed that instances of cancer increased in direct proportion to the amount of radiation absorbed over 100 millisieverts. That is, if person A had double the exposure of person B, person A had double the chance of developing cancer.

According to the National Institute of Radiological Sciences, if 1,000 people absorb a radioactive dose of 100 millisieverts, 305 will eventually die of cancer -- five more than the norm. However, there is no clear evidence of if or how lower doses influence the chances of developing cancer, as a whole series of other factors including eating habits and smoking affect a person's chances of getting the disease. Complicating studies of lower exposure levels, research on the effects of about a 10 millisievert dose, for example, would require 10 million test subjects exposed to that amount of radiation.

Furthermore, scientific opinion on the existence of clearly defined safe and unsafe doses is divided, with some claiming that there is a concrete threshold under which there are no health effects, and others insisting on the "Linear No Threshold (LNT) hypothesis," which states that radiation exposure is harmful at any dose.

The International Commission on Radiological Protection (ICRP), which has a strong influence on radiation regulations in many countries and has drawn up a set of standard values based on the LNT hypothesis, states that anti-radiation precautions can be effective as long as risks are not underestimated.

"We must consider the monetary and social costs of any anti-radiation measures when considering what extent we can protect ourselves from low radiation doses," states Kyoto University professor emeritus and ICRP steering committee member Otsura Niwa.

Gov't, experts must release criteria for radiation safety around nuke plant

[a shocking article really, all the more so because it sounds so reasonable]

"Resigning was the worst choice, wasn't it?" says an e-mail I received from one of my colleagues late last week. It referred to the resignation of University of Tokyo professor and radiation expert Toshiso Kosako as an adviser to the Cabinet Secretariat.

Kosako tearfully criticized the government for what he calls its "lax" response to the crisis at the tsunami-hit Fukushima No. 1 Nuclear Power Plant when he announced his departure at a news

conference. My colleague fears that Kosako's abrupt and emotional announcement could fuel local residents' concern about radiation leaks from the crippled power station.

There are two kinds of health hazards that radioactive material can cause -- immediate tissue damage from high levels of radiation, and chromosomal damage that increases the risk of cancer in the future even if the amount of radioactive material is small.

Radiation in areas dozens of kilometers away from the plant is far below the level that could immediately damage tissues. Therefore, the government asserts that the radiation "will not pose an immediate threat to human health."

On the other hand, if people are exposed to even a small amount of radiation, experts say it will slightly increase the risk of cancer in the future. Children in particular are vulnerable to radioactive substances. This is what residents of Fukushima Prefecture are worried about.

However, if children living in Fukushima Prefecture suffer from cancer in the future, it will be impossible to prove a causal relationship between their exposure to radiation and the disease. Even experts are divided over whether and how far the Chernobyl nuclear crisis will affect the health of nearby populations from a long-term perspective. **In short, health hazards that radiation can cause have not been clarified.**

We need to consider how to deal with such a slight rise in health hazards caused by radiation, but **there is too little information available to make that judgment. [the information exists but you've got to be willing to see it]**

Professor Kosako voiced objections to the government's repeated assertions that the situation is safe. However, his warning that the situation is dangerous without showing clear evidence also fuels the public's anxiety.

Both the government and experts like Kosako are required to show the public clear criteria for judging whether the situation is safe or dangerous. It is Fukushima Prefecture residents, rather than Kosako, who really want to cry over the ongoing nuclear crisis. (By Etsuko Nagayama, Tokyo Science and Environment News Department)

QUEST-FRANCE

Hier, pour la première fois depuis le séisme et le tsunami qui ont endommagé la centrale, treize ouvriers ont pénétré dans le bâtiment du réacteur n° 1, dont le toit avait été soufflé par une explosion. Équipés de combinaisons et munis de bouteilles d'oxygène, ils ont travaillé pendant une heure et demie, **[il était prévu qu'ils y restent 40 minutes voir Mainichi]** se relayant par petits groupes. Ils ont connecté huit tubes à des ventilateurs conçus pour filtrer les éléments radioactifs présents dans l'air. Un système qui restera en place deux ou trois jours. Ce qui devrait, par la suite, faciliter les travaux de réparation des circuits de refroidissement, pour l'instant freinés par la radioactivité, trop élevée.

.../...

L'opérateur Tepco, propriétaire de la centrale, pense pouvoir réussir à refroidir les réacteurs et les arrêter, d'ici au début de l'année prochaine. L'Institut français de radioprotection et de sûreté nucléaire (IRSN) estime néanmoins que la situation demeure « préoccupante ». De l'eau douce – dont le pompage reste délicat – est toujours injectée pour refroidir les installations. Hier, sujet d'inquiétude, la température qui s'élève à 240 °C était en hausse dans le réacteur n° 3.

.../...

Eau contaminée rejetée en mer : quel impact ?

Le niveau des substances radioactives a fortement augmenté, à une quinzaine de kilomètres au large de Fukushima. Les échantillons collectés indiquent des niveaux de césium 137, 600 fois supérieurs à ceux trouvés jusqu'alors. L'IRSN estime que cette pollution affectera l'environnement marin. Des poissons et des algues consommées au Japon pourraient accumuler des radionucléides, comme l'iode 131.

http://www.ouest-france.fr/actu/actuDet_-Fukushima-des-ouvriers-dans-le-reacteur-no-1-3637-1787816_actu.Htm?xtor=RSS-4&utm_source=RSS_MVI_ouest-france&utm_medium=RSS&utm_campaign=RSS

E POINT

La France se penche sur sa gestion des conséquences d'une crise nucléaire

Le Point.fr - Publié le 05/05/2011 à 18:59 - Modifié le 05/05/2011 à 19:02

L'exemple japonais rappelle que l'Hexagone doit encore améliorer ses dispositifs en cas d'accident nucléaire.

.../...

jeudi et vendredi à Paris un séminaire de réflexion du **Comité directeur pour la gestion de la phase post-accidentelle d'un accident nucléaire ou d'une situation d'urgence radiologique (Codirpa)**, destiné à élaborer une doctrine française en la matière. Simple hasard de calendrier, puisque cette réunion de tous les acteurs du nucléaire français avait été programmée dès 2007.

.../...

Premier constat, les acteurs concernés (exploitants, autorités de contrôle, associations, pouvoir publics...) en sont encore **au stade de la "réflexion"**. C'est le président de l'Autorité de sûreté nucléaire française (ASN) lui-même, André-Claude Lacoste, qui en fait l'aveu.

.../...

Les réflexions du Codirpa devraient notamment déboucher sur un "guide de sortie de la phase d'urgence" après un accident nucléaire. Il devrait être publié au cours de l'année 2011. Ses préconisations sont "en cours d'expérimentation sur trois sites" nucléaires, ceux de Tricastin, de Fessenheim et de Civaux.

http://www.lepoint.fr/societe/la-france-se-penche-sur-sa-gestion-des-consequences-d-une-crise-nucleaire-05-05-2011-1327399_23.php

France : Cette petite phrase nous vient du directeur général de l'IRSN, Jacques Repussard :

"Notre pays doit **accepter de se préparer à des accidents nucléaires 'complètement inimaginables'**, qui représentent le plus grand danger pour ses installations, comme le prouve la catastrophe de Fukushima.".../...

"Si un accident se produit, le moins invraisemblable est que ce soit un accident absolument extraordinaire, lié par exemple à des effets dominos avec d'autres installations voisines, des aléas naturels ou des actes de malveillance. Il faut se préparer à ce type de scénarios", a averti le responsable de l'IRSN jeudi, dans le cadre d'une audition de la mission parlementaire sur la sûreté des installations nucléaires.

Right choice to close Hamaoka nuke plant, but other reactors also a concern

The Hamaoka nuclear power plant operated by Chubu Electric Power Co. is pictured in Omaezaki, Shizuoka Prefecture, from a Mainichi helicopter in this February 2011 photo. (Mainichi)

As the Fukushima nuclear crisis rages on, Prime Minister Naoto Kan has demanded that Chubu Electric Power Co. shut down all reactors at its Hamaoka nuclear plant, fearing the facility near an earthquake danger zone is another nuclear disaster waiting to happen.

The Hamaoka plant in Shizuoka Prefecture sits on the edge an area where experts expect the next great Tokai earthquake to have its epicenter sometime in the relatively near future -- a vital piece of seismological information unknown at the time the plant was built. If the builders had known, they would have avoided the area. We in the press have certainly pointed out the risks.

Are earthquakes and tsunami really so powerful? Are the effects of a nuclear disaster really so grave? The Great East Japan Earthquake of March 11 gave us a clear answer to these questions.

If by any chance another terrible accident strikes, just as the prime minister stated, the consequences for all of Japan would be grave indeed.

Since the March 11 disaster, Chubu Electric has set about a number of tsunami safety projects including the construction of breakwaters. However, it is impossible to guarantee that a Tokai quake won't hit before these projects are finished. Major temblors are also possible in broad expanses of the seas off the east coast of Japan. As such, Kan's request that the Hamaoka reactors be shuttered before the mid- to long-term disaster safety projects have been completed is absolutely the correct decision, and we praise him for it. Furthermore, Chubu Electric has no choice but to comply.

One point that needs to be mentioned, however, is that even if the reactors are shut down, guaranteeing the safety and security of the plant's nuclear fuel must be an ongoing enterprise. Looking at the Fukushima nuclear crisis, it becomes obvious that continued cooling of spent fuel rods is of utmost importance.

Reactors at the Hamaoka Nuclear Power Plant are pictured in this photograph taken from a Mainichi helicopter in February 2011. (Mainichi)

In his stated reasons for demanding the Hamaoka plant be shut, Kan cited the prediction by the government's Headquarters for Earthquake Research Promotion that there was an 87 percent chance of a magnitude 8 earthquake striking the Tokai region in the next 30 years.

On the other hand, the government body's predictions are not 100-percent guaranteed to come true. In fact, nothing like the magnitude 9 quake that hit northeast Japan in March was ever even considered by the headquarters. No guarantee can be made to areas with low chances of a quake that no seismic disaster lays in their future. In fact, the Great East Japan Earthquake may have stimulated seismic activity all over the country, in places both high and low risk.

With this in mind, we call on the government not to overlook Japan's other nuclear power plants. We remain concerned that emergency response measures, to continuously keep nuclear fuel cool and reactors stable in the event of a disaster, are not sufficient. Furthermore, with attention now so focused on tsunami safety projects, neglect of measures to deal with the vibrations from an earthquake cannot be allowed.

There are probably many people worried about what effect closing the Hamaoka plant will have on the country's power supply, and the government must prevent any confusion on this point.

Chubu Electric puts off decision on nuke plant suspension

The Hamaoka nuclear power station in Omaezaki, Shizuoka Prefecture, is pictured in this aerial photo taken from a Mainichi helicopter on Feb. 23, 2011. (Mainichi)

NAGOYA (Kyodo) -- Chubu Electric Power Co. held an inconclusive board meeting Saturday over whether to suspend the Hamaoka nuclear power plant in Shizuoka Prefecture as requested by Prime Minister Naoto Kan for safety reasons, participants said.

The utility serving central Japan surrounding Nagoya will continue talks Sunday or later, they said after the meeting where discussions are believed to have centered on the suspension's anticipated impact on its business and how to ensure a stable energy supply without its only nuclear power plant.

The plant in the city of Omaezaki accounts for about 11.7 percent of the utility's total supply.

Suspending it is projected to lead to a loss of about 3.6 million kilowatts of the firm's estimated output of up to 30.89 million kilowatts against the projected peak demand of 27.09 million kilowatts in the summer, according to the government's Nuclear and Industrial Safety Agency.

The Nagoya-based power company will likely study alternative sources such as its thermal power plants and procuring electricity from other utilities, company sources said.

At a hastily arranged news conference Friday evening, Kan said all operations at the Hamaoka plant must be suspended due to concerns that a powerful earthquake could hit the area and trigger another serious nuclear crisis in addition to the one ongoing at a Tokyo Electric Power Co. plant in Fukushima Prefecture.

Economy, Trade and Industry Minister Banri Kaieda, second from left, listens to explanations by Chubu Electric Power Co. employees near a sand embankment in front of the Hamaoka Nuclear Power Plant in Omaezaki, Shizuoka Prefecture, on May 5, 2011. (Mainichi)

Chubu Electric President Akihisa Mizuno responded in a statement late Friday that the utility will "swiftly consider" the premier's request. One official said Saturday morning, "A business judgment at the highest level is required. It is important that we make a decision swiftly and notify society of it."

But as Kan has admitted that the request is not based on law, some people within Chubu Electric remain reluctant to immediately comply with it, the sources said.

In summer, energy demand, chiefly for air conditioning, climbs 800,000 kilowatts for each 1 C rise in the temperature, the utility says.

If it is to meet all the demand only with thermal power generation, the additional fuel cost would be 700 million yen per day, or about 250 billion per annum, according to the firm.

Omaezaki Mayor Shigeo Ishihara complained Saturday about Kan's request, telling a press conference, "It will have a large impact on (local) employment. I wanted him to listen more to local opinions," adding that the local assembly is united in seeking enhanced safety steps while keeping the plant running.

The request is not intended to halt the country's entire nuclear program and was made after confirming that it will not damage the economy of the Chubu region in central Japan, Goshi Hosono, one of Kan's aides from the ruling Democratic Party of Japan, said on a TV talk show the same day.

He and Economy, Trade and Industry Minister Banri Kaieda have inspected the plant but "could not fully dispel concerns" about a possible accident, Hosono said.

Actu-Environnement :

Fukushima : deux options de refroidissement des réacteurs opposent les experts

Depuis le 5 mai, Tepco, l'exploitant de la centrale, tente de rétablir le refroidissement du réacteur numéro 1. Si la création d'un circuit fermé est privilégiée, certains experts sont dubitatifs et proposent plutôt de noyer les réacteurs.

[Climat](#) | 06 Mai 2011 | [Actu-Environnement.com](#)

[Réduire la taille du texte](#)[Augmenter la taille du texte](#)[Imprimer cette page](#)[Options de partage](#)

Ouvrier de Tepco mesurant la radioactivité au sein du bâtiment du réacteur n°1 de la centrale

La catastrophe de Fukushima a quitté progressivement le devant de la scène médiatique, mais [la situation est instable](#) et reste "*très sérieuse*" selon l'expression utilisée quotidiennement dans les bulletins de l'Agence internationale à l'énergie atomique (AIEA) .

Des ouvriers dans le bâtiment du réacteur numéro 1

Jeudi 5 mai, Tepco a annoncé que pour la première fois depuis le 11 mars, des ouvriers sont entrés dans le bâtiment du réacteur numéro 1. Objectif : installer des équipements de ventilation équipés de filtres afin d'[abaisser le niveau de radioactivité à l'intérieur du bâtiment](#).

Dans un premier temps, deux employés de Tepco sont entrés dans le bâtiment pour mesurer la radioactivité pendant 25 minutes. Selon les informations fournies par l'opérateur, celle-ci irait de 10 à 93 millisieverts par heure (mSvt/h). Ensuite, neuf employés de sous-traitants se sont relayés pendant 90 minutes pour relier le bâtiment à une ventilation située dans le bâtiment des turbines. Ces derniers étaient accompagnés de deux employés chargés de contrôler la radioactivité. Tepco a précisé que durant cette opération, les ouvriers ont été exposés à un maximum de 3,16 mSvt, soit environ 12% de la dose annuelle autorisée dans le contexte de la catastrophe en cours.

Avec cette opération, l'exploitant espère abaisser de 90% le niveau des radiations dans le bâtiment pour y installer un système de refroidissement à partir du 8 mai et rétablir le refroidissement en juin.

Rétablir un circuit de refroidissement

Actuellement, le refroidissement des réacteurs est assuré par des injections d'eau via des vannes d'incendie. Cependant, ces circuits n'étant pas fermés et les enceintes de confinement n'étant plus parfaitement étanches, cette eau coule à l'extérieure et stagne dans les parties basses de la centrale. Il y aurait actuellement environ 90.000 m³ d'eau hautement radioactive sur le site. Un volume qui croît, malgré [l'opération de pompage débutée mi-avril](#). Cette opération devait permettre d'évacuer en 26 jours les 10.000 m³ présents au niveau du réacteur numéro 2. Après 10 jours de pompage, 2.390 m³ ont été évacués.

Avec le système de refroidissement que souhaite installer Tepco, le maintien à froid du réacteur deviendrait possible tout en limitant les fuites. Ce système serait proche du refroidissement normal puisqu'un premier circuit clos permettrait d'injecter de l'eau froide et l'eau chaude récupérée serait refroidie via un échangeur de chaleur relié à un second circuit. Un avantage annexe de cette stratégie

est de fournir un exutoire pour l'eau hautement radioactive puisqu'elle pourrait être utilisée dans le circuit primaire du système de refroidissement.

Le même type de circuit est envisagé pour les réacteurs 2 et 3, mais Tepco n'a pas annoncé de date pour le début des travaux.

La NISA envisage de noyer le réacteur

Si personne ne remet en cause l'efficacité de l'option retenue par Tepco, certains observateurs doutent cependant qu'il soit possible de rétablir un circuit de refroidissement. En effet, ils jugent que la tâche est trop complexe et que les conditions de travail dans le bâtiment ne permettent pas de la mener à bien.

Par ailleurs ils soulignent que la situation presse et que les variations de la pression et de la température dans les réacteurs témoignent de l'instabilité de la situation et d'une possibilité d'aggravation rapide.

L'Agence de sûreté nucléaire japonaise (NISA) a donc demandé à Tepco de lui soumettre un plan alternatif, surnommé "*water tomb*". Il s'agit non plus de refroidir le réacteur via un circuit, mais de le noyer en remplissant d'eau l'enceinte de confinement. Cependant, cette solution a également ses détracteurs. Ces derniers estiment que si l'eau contaminée provient du réacteur, c'est un signe de la perte d'étanchéité de l'enceinte. Tenter de la remplir ne ferait qu'augmenter les fuites radioactives.

Tepco a étudié cette option et soumis, en réponse à la demande de la NISA, un rapport qui démontre que cette stratégie pourrait refroidir efficacement les réacteurs sans que les tonnes d'eau injectées ne menacent l'intégrité de l'enceinte de confinement. Il conviendrait néanmoins de renforcer les piliers de la chambre de surpression située sous l'enceinte de confinement.

Radiation levels drop inside troubled No. 1 reactor building

This photo shows the installment of ducts inside the No. 1 nuclear reactor building. (Photo courtesy of Tokyo Electric Power Co.)

TOKYO (Kyodo) -- Radiation levels have dropped inside the building housing the No. 1 reactor at the crippled Fukushima Daiichi nuclear power plant, the plant's operator said Saturday, a development that would pave the way for workers to reenter the site to stabilize the reactor.

The operator, Tokyo Electric Power Co., known as TEPCO, attributed the drop to a ventilator installed in the building on Thursday to filter out radioactive substances inside.

TEPCO has been struggling to bring the six-reactor complex in Fukushima Prefecture under control ever since the March 11 tsunami triggered by a major earthquake knocked out the plant's vital cooling functions and severely crippled the Nos. 1 to 3 reactors with nuclear fuel left inside their cores.

Radiation levels rose Friday, but TEPCO said it occurred because the ventilator stirred the air inside the building, leading a temporary spike.

The lower levels would reduce the risk of plant workers being exposed to elevated levels of radiation when they build a new cooling system for the reactor inside the building.

TEPCO is planning to open doors that connect the building and an adjacent turbine building soon, possibly on Sunday afternoon, to begin work on building the cooling system. But leaving them open for a long period of time would risk releasing radioactive substances into the air through a damaged part of the reactor building, the utility said.

A worker checks the radiation level inside the No. 1 reactor of the Fukushima No. 1 Nuclear Power Plant on May 5. (Photo courtesy of Tokyo Electric Power Co.)

The company will therefore assess the possible environmental impact of the move and seek an appraisal from the government before opening the doors.

Earlier Saturday, TEPCO officials said around 800 workers have spent more than a month dealing with the nuclear crisis at the power plant, but **they have only recently started to undergo medical checkups.**

It took nearly two months after the crisis erupted following the March 11 quake and tsunami to commence regular health checks as the health ministry had initially only required them to be performed after the crisis ends, assuming it would not be prolonged, according to the officials.

Of the workers, 30 have been exposed to over 100 millisieverts of cumulative radiation. However, with the exception of three workers exposed on March 25 to high-level radiation and those who have already ceased working at the plant, the workers only began to undergo their first examinations this month, the officials said.

The checks came after the Health, Labor and Welfare Ministry instructed employers on April 25 to immediately examine the health of workers who have been dealing with the crisis for more than a month or who have been exposed to more than 100 millisieverts of radiation.

Around 500 employees of the utility and about 300 workers from its affiliates and other companies have worked at the troubled plant for more than a month, with several hundred workers per day engaging in on-site efforts to contain Japan's worst ever nuclear accident, according to TEPCO.

However, they have only just begun to meet doctors commissioned by their employers as part of what will be monthly checkups as it took time to determine the number of such workers, the officials said.

This Sunday, April 10 image taken by T-Hawk drone aircraft and released by Tokyo Electric Power Co. (TEPCO) shows the damaged reactor building of Unit 1 of the tsunami-crippled Fukushima Dai-ichi nuclear power plant in Okuma town, Fukushima Prefecture, northeastern Japan.(AP Photo/Tokyo Electric Power Co.)

Initially, the ministry told the employers on March 16, a day after it raised the legal limit for radiation exposure in an emergency to 250 millisieverts from 100 millisieverts to deal with the current crisis, to check the health of workers exposed to over 100 millisieverts after they finish their work.

Although six workers had been exposed to more than 100 millisieverts of radiation as of March 19, no checkups were performed amid the continuing crisis, prompting the ministry to issue its updated directive more than a month later, the officials said.

The number reached 30 on April 23, including the three who on March 25 stepped into a highly radioactive pool of water while laying cable in the basement of the No. 3 reactor's turbine building as part of efforts to restore the plant's cooling functions.

minute amount of radiation leaked from Tsuruga plant (15.06) le 9 mai_

Workers measure radiation inside troubled No. 1 reactor

TOKYO, May 9, Kyodo

Workers battling the nuclear crisis at the Fukushima Daiichi power plant measured radiation inside the No. 1 reactor building early Monday to clear the way for full-scale work to stabilize the country's worst-ever nuclear emergency after a nearly two-month delay.

The move came after plant operator Tokyo Electric Power Co. opened the doors linking the reactor building to its adjacent turbine building Sunday evening, and confirmed that the resultant release of radioactive materials into the air had not raised radiation levels on the premises, according to the firm.

Nine workers went into the reactor building around 4:20 a.m. and measured radiation and other conditions inside for about 30 minutes, the utility known as TEPCO said, **without immediately announcing the radiation**

If the radiation level is confirmed to be safe for workers to operate inside, they will start building a new cooling system for the reactor -- the most severely damaged of the six at the plant -- which lost cooling functions in the March 11 quake and tsunami.

In this Friday May 6, 2011 image from video footage released on Sunday May 8, 2011 by Tokyo Electric Power Co., workers are seen on the first floor of the turbine building of the Unit 1 reactor building at the crippled Fukushima Dai-ichi nuclear power plant in Okuma town, Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

Restoration work at the reactor has been hampered by a hydrogen explosion on March 12 and high radiation levels since.

In the envisaged next step, workers will install and adjust equipment including a heat exchanger and instruments to measure the water levels in the reactor's pressure vessel containing nuclear fuel and the containment vessel shrouding it, the company said.

No rises in the radiation level have been seen at nine observation points in the plant located some 220 kilometers northeast of Tokyo since the double-entry doors were opened shortly past 8 p.m. Sunday, TEPCO said.

The government's Nuclear and Industrial Safety Agency and the Environment Ministry began measuring the same day radiation levels in debris left by the quake-tsunami disaster in Fukushima Prefecture to consider ways to dispose of it and address the fears of local people.

The debris has been stored at makeshift scrap yards in coastal and central areas of the prefecture due to fears of contamination with radioactive materials.

The agency will check radiation levels on the surface of rubble at 12 locations and bring back samples to Tokyo for analysis. The ministry will gauge radiation in the air at some 120 scrap yards and their vicinity, except in areas from which people have been or will soon be evacuated.

(Mainichi Japan) May 9, 2011

Small amount of radioactive gas leaks from Tsuruga nuke plant

FUKUI, Japan, May 9, Kyodo

A small amount of radioactive gas leaked from a nuclear power plant in Tsuruga, Fukui Prefecture, but there is no impact on the surrounding environment, the plant's operator Japan Atomic Power Co. said Monday.

Man made to work at Fukushima plant for 2 weeks without prior knowledge

OSAKA, May 9, Kyodo

An Osaka man was made to work at the crippled nuclear power plant in Fukushima Prefecture for about two weeks, when he had been expecting to work in neighboring Miyagi Prefecture, said a job placement center in Osaka on Monday.

The worker in his 60s received daily wages of about 24,000 yen, double the sum he was initially promised, but complained that the pay undervalued the work he did at the Fukushima plant, the Nishinari labor welfare center said after interviewing the man and the company that hired him.

"I was finally issued with a radiation dosimeter on my fourth day of work there," he was quoted as saying.

With New Nukes Unlikely, US To Supercharge Aging Reactor Fleet

May. 8 2011 - 8:11 am <http://blogs.forbes.com/jeffmcmahon/2011/05/08/with-new-nukes-unlikely-us-to-supercharge-aging-reactor-fleet/>

The United States can generate the power equivalent of seven new nuclear reactors by upgrading its current fleet, according to the Department of Energy.

DOE took an important step last week toward increasing the power output and extending the life of existing reactors.

Scientists launched a “virtual reactor” Tuesday at DOE’s Consortium for Advanced Simulation of Light Water Reactors (CASL) in Oak Ridge, Tennessee. The software will model the performance of the country’s aging light-water reactors so scientists can determine how to make them burn more fuel more intensely and more efficiently—and for a longer lifetime.

“These upgrades could improve the energy output of our existing reactor fleet by as much as seven reactors’ worth at a fraction of the cost of building new reactors, while providing continued improvements in reliability and safety,” DOE [announced](#).

At a recent [forum](#) in Chicago, an official from Argonne National Laboratory predicted this would become the U.S. nuclear strategy:

“I think the prospects for new plants are very limited,” said Hussein Khalil, head of Argonne’s Nuclear Energy Division. “But I think we’ll try to keep our existing plants going and try to get the most out of them. As long as we can safely do that.”

CASL will investigate ways to extend the life of existing U.S. reactors, an effort likely to ruffle the feathers of local opponents nationwide who are looking forward to the expiration of reactor licenses. DOE sees license extension as a way to reduce the per unit cost of nuclear power: new energy with little or no new capital costs.

Without extensions, the U.S. faces a sudden drop in nuclear power output.

U.S. officials envisioned that reactors would operate for 60 years, with a 40-year initial license and one 20-year extension, but [according](#) to the Energy Information Administration, that schedule “would result in the retirement of more than one-third of existing U.S. nuclear capacity between 2029 and 2035.”

To extend the life of reactors, the CASL team has to determine the effects of increased radiation and aging on the integrity of the reactor vessel, internal components, containment and piping.

The scientists will also investigate ways of “uprating” the power output of existing reactors, which risks damage to structures, systems, and components, fuel and steam generator integrity and may violate existing safety limits.

They will seek ways to burn more fuel more efficiently to reduce nuclear waste production, but first they have to determine whether the fuel system can handle the strain. The Consortium released a [slideshow](#) outlining these goals and risks.

The U.S. has 104 nuclear reactors, 50 of which have received license renewals, according to EIA. They supply about 20 percent of the nation's electricity.

Two new reactor projects are expected to receive construction permits this year, in [Georgia and South Carolina](#), but those projects advanced through the permit process before a series of setbacks that is [expected to delay](#) the permitting of more new reactors for several years.

Those setbacks include reduced energy demand, a drop in the price of natural gas, and safety concerns stemming from the Fukushima disaster in Japan.

“Nuclear energy is our nation's largest source of carbon-free power and is an important part of our energy mix moving forward,” said Secretary of Energy Steven Chu. “Work done at this facility will help make our fleet of reactors even safer and more efficient while creating jobs, fueling the economy and saving consumers money on their utility bills.”

CASL is a hub of laboratories headquartered at Oak Ridge National Laboratory. Its partner institutions include the Electric Power Research Institute, Idaho National Laboratory, Los Alamos National Laboratory, Massachusetts Institute of Technology, North Carolina State University, Sandia National Laboratories, Tennessee Valley Authority, University of Michigan and the manufacturer of the new reactors in the southeast: Westinghouse Electric Company.

France to Test 58 Reactors for Surviving Earthquakes, Not Terrorist Attack

By Tara Patel - May 9, 2011 1:40 PM GMT+0200 <http://preview.bloomberg.com/news/2011-05-09/france-to-test-58-reactors-for-surviving-earthquakes-not-terrorist-attack.html>

Safety reviews at Electricite de [France](#) SA's 58 atomic reactors in France will cover their vulnerability to earthquakes and floods and exclude terrorist attacks, the nation's atomic regulator said.

“We don't think there could be a serious study,” of risks caused by terrorism nor could it be done transparently, the head of the Autorite de Surete Nucleaire, Andre-Claude Lacoste, said at a briefing in Paris today. “This will be discussed at the end of the week in Brussels. It's not a dogmatic position.”

Prime Minister Francois Fillon had asked the regulator to evaluate whether French plants can withstand earthquakes, floods, power outages and cooling-system failures. The European Union is also planning to carry out “stress tests” in the second half of the year in response to the Japanese atomic accident caused by a March 11 earthquake and tsunami.

The EU aims to reveal the criteria for tests on its 143 atomic plants on May 12, the same day that national regulators in Europe are due to give their approval to the plans, European Energy Commissioner Guenther Oettinger has said.

Lacoste said France's criteria may differ from the EU's. "There is no assurance of a total convergence" between what France announced today and what the EU will decide later this week. He said the French have based their decisions "as much as possible" on what is known now about the European process and that of other countries.

Testing 58 Reactors

Nuclear power stations owned by companies including state- owned EDF and [Germany's RWE AG \(RWE\)](#) produce about a third of the electricity in the EU, which wants to draw up common safety criteria after the Japanese crisis triggered public protests in Europe against atomic power.

The French watchdog is preparing the stress tests, which also will exclude fuel-transport mishaps, on EDF's 58 existing reactors that produce more than 75 percent of the nation's electricity as well as one being built at Flamanville in Normandy. Lacoste has raised the possibility of a construction halt at Flamanville in the coming months if lessons learned from Fukushima require changes to improve safety.

"We will take any measures that are necessary," he said when asked whether any EDF reactors could be shut down as a consequence of safety issues or whether the operator may be obliged to build containment facilities over spent fuel pools at plants.

Fukushima was a "massive event" that is being taken more seriously in [Europe](#) than in [Russia](#) and the U.S., he said. "There is clearly a before Fukushima and an after Fukushima."

About 15 nuclear facilities that are related to reactors also will be reviewed, including waste storage and treatment plants, the ASN said.

Fukushima's No. 1 reactor building radiation up to 700 millisieverts

In this Friday May 6, 2011 image from video footage released on Sunday May 8, 2011 by Tokyo Electric Power Co., workers are seen on the first floor of the turbine building of the Unit 1 reactor building at the crippled Fukushima Dai-ichi nuclear power plant in Okuma town, Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

TOKYO (Kyodo) -- The operator of the Fukushima Daiichi nuclear power plant found that the radiation level of the building housing the troubled No. 1 reactor stood at up to 700 millisieverts per hour, the government's nuclear agency said Monday, citing the need for radiation shielding to proceed with work to bring an end to the nuclear crisis.

The radiation level, which was around 10 millisieverts per hour at its lowest, was measured as Tokyo Electric Power Co. workers and agency officials entered into the No. 1 reactor building early Monday as part of preparations to start full-scale work to create a system to stably cool the damaged nuclear fuel inside.

"An area with a double-digit millisievert level, let alone three-digit figures, is quite tough as a working environment. So we have to do the work by using some shielding," Hidehiko Nishiyama, a spokesman for the Nuclear and Industrial Safety Agency, told a press conference.

As for ways to shield against radiation, the utility known as TEPCO is considering making a metal tunnel for people to walk through, or using some lead sheeting, according to Nishiyama.

TEPCO officials said that the high radiation level is so far unlikely to affect the utility's schedule to stabilize the plant's troubled reactors around October at the earliest, but **it is uncertain whether things will go as planned because of the difficult working environment.**

Workers dealing with the crisis triggered due to the March 11 earthquake and tsunami are allowed to be exposed to radiation levels no higher than 250 millisieverts. **They can only stay for some 20 minutes in the most contaminated area of the No. 1 reactor building.**

In this Friday May 6, 2011 image from video footage released on Sunday May 8, 2011 by Tokyo Electric Power Co., workers are seen on the first floor of the turbine building of the Unit 1 reactor building at the crippled Fukushima Dai-ichi nuclear power plant in Okuma town, Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

Still, TEPCO believes that restoration work is possible inside the No. 1 reactor building because the radiation level of areas where workers would need to stay is between 10 to 70 millisieverts per hour.

The latest move came after TEPCO opened the doors linking the reactor building to its adjacent turbine building Sunday evening, and confirmed that the resultant release of radioactive materials into the air had not raised radiation levels on the premises and nearby areas as of 5 a.m. Monday, according to the firm.

By opening the double-entry doors, air containing about 500 million becquerels of radioactive substances is believed to have been released into the atmosphere from the upper part of the No. 1 reactor building, which was damaged in a hydrogen explosion that occurred at the early days of the nuclear crisis.

Seven TEPCO workers and two nuclear regulatory agency officials went into the reactor building around 4:20 a.m. and measured radiation and other conditions inside for about 30 minutes. The nine were exposed to radiation between 2.7 millisieverts and 10.56 millisieverts, the agency said.

Under the current plan, TEPCO will fill the No. 1 reactor's primary containment vessel with water to a level above the nuclear fuel inside, and start operating by June an air-cooling device aimed at reducing the temperature of the water circulating around the reactor.

Now that workers have entered the No. 1 reactor building, TEPCO plans to have them install and adjust instruments to measure the water levels in the reactor's containment vessel, and place a heat exchanger.

Restoring the cooling systems of the plant's reactors, which were lost in the wake of the March 11 quake and tsunami, is seen as vital to end the country's worst nuclear crisis, as the current emergency measure of continually injecting water from outside has created vast pools of highly radioactive water within the plant.

The nuclear agency and the Environment Ministry began measuring the same day radiation levels in debris left by the quake-tsunami disaster in Fukushima Prefecture in order to consider ways of disposing of it and addressing the fears of local people.

The debris has been stored at makeshift scrap yards in coastal and central areas of the prefecture due to fears of contamination with radioactive materials.

The agency will check radiation levels on the surface of rubble at 12 locations and bring back samples to Tokyo for analysis. The ministry will gauge radiation in the air at some 120 scrap yards and their vicinity, except in areas from which people have been or will soon be evacuated.

Recovery of fallen device from Monju reactor slated for June

TOKYO, May 10, Kyodo

The Japan Atomic Energy Agency will undertake the work in June of recovering a fallen 3.3-ton device from its prototype fast-breeder reactor Monju in Tsuruga, Fukui Prefecture, agency officials said Tuesday.

Japan Scraps Plan for New Nuclear Plants

http://www.nytimes.com/2011/05/11/world/asia/11japan.html?_r=1&partner=rss&emc=rss

TOKYO — Prime Minister [Naoto Kan](#) said Tuesday that [Japan](#) would abandon plans to build new nuclear reactors, saying his country needed to “start from scratch” in creating a new energy policy.

Mr. Kan’s announcement came as Japan allowed residents of evacuated areas around the stricken Fukushima Daiichi nuclear plant to briefly revisit their homes for the first time since the devastating earthquake and tsunami in March caused the nuclear accident.

Tuesday’s decision will abandon a plan that the Kan government released last year to build 14 more nuclear reactors by 2030 and increase the share of nuclear power in Japan’s electricity supply to 50 percent. Japan currently has 54 reactors that before the earthquake produced 30 percent of its electricity.

The cancellation of the planned nuclear plants is the second time that Mr. Kan has suddenly announced big changes in Japanese nuclear policy without the usual endless committee meetings and media leaks that characterize the country’s consensus-driven decision making. Mr. Kan appears to be seeking a stronger leadership role after criticism of his government’s sometimes slow and indecisive handling of the Fukushima accident.

Last week, Mr. Kan asked a utility company to suspend operations at the Hamaoka nuclear plant, which sits atop an active earthquake fault line, about 120 miles southwest of Tokyo. After three days of delays, the company, Chubu Electric Power, finally agreed on Monday to shut down the plant until a new wave wall was built and other measures could be taken to strengthen it against earthquakes and tsunamis.

Mr. Kan said Japan would retain nuclear and fossil fuels as energy sources, but vowed to add two new pillars to Japan’s energy policy: renewable energy and conservation. While Japan has been a global leader in energy conservation, it lags behind the United States and Europe in adopting solar and wind power, and other new energy sources.

“We need to start from scratch,” Mr. Kan told reporters. “We need to make [nuclear energy](#) safer and do more to promote renewable energy.”

Mr. Kan had also previously called for Japan to sell its nuclear technology to emerging nations as a new source of export income. However, the Fukushima accident has prompted a global rethinking of nuclear energy and may drive customers away from Japanese suppliers to rivals in places like South Korea.

Mr. Kan also appeared to pull back from his earlier vows to remain committed to nuclear power. His apparent about-face may be driven partly by public opinion, which has soured on nuclear power since the Fukushima accident.

On Tuesday, Japan was reminded of the human costs of the disaster, when the first group of 92 people paid two-hour visits to their homes in the town of Kawauchi, within the 12-mile zone around the plant that was evacuated after the nuclear crisis.

The residents wore white anti-radiation clothing and traveled in buses under tight supervision by nuclear officials. They retrieved belongings such as photo albums and the small tablets traditionally used in Japan to honor dead relatives in household Buddhist shrines, according to local media reports.

The Kan government appeared to agonize for weeks over whether to allow even such brief trips. Officials were concerned about whether civilians could be kept safe from exposure to potentially high radiation doses around the plant.

Complicating their decision was the lack of scientific knowledge on the health effects of the radiation doses now seen in many of the evacuated areas. Some scientists say radiation levels even in many evacuated areas are too low to cause immediate illness while others worry that incidence of cancer could rise over the long term.

Last week, the government staged a trial run, in which officials played the role of returning residents, to see if the trips could be made safely, and within the time allotted. Screened for radiation on their return, those participating were found to have been exposed to a dose of up to 25 microsieverts during the two-hour visit.

That is well above the 3.8 microsieverts per hour that Japan has used in some cases as a threshold for deciding such safety issues as whether to allow children to play outside while at school.

Suspension of Hamaoka nuke plant sparks battle between common sense and outdated thinking

The suspension of operations at the Hamaoka Nuclear Power Plant in Shizuoka Prefecture, which is widely regarded as vulnerable to a powerful earthquake and tsunami, will adversely affect production and employment in central Japan. Moreover, the move will certainly contribute to public opinion against nuclear power generation and spark demands that other nuclear power stations be also closed.

However, is the decision to shut down the plant really a reckless move? Rather, calls for the continued consumption of electric power by all means should be called irresponsible.

Nearly 100,000 residents near the tsunami-hit Fukushima No. 1 Nuclear Power Plant have been evacuated from their hometowns and deprived of their jobs, and are at a loss what to do. Those who are remaining in their neighborhoods around the plant fear possible contamination of the air, water and soil from radiation leaking from the crippled plant.

Agricultural products from Fukushima and fish caught off the prefecture are not selling well because groundless rumors that such products are contaminated with radiation have spread throughout the country. Moreover, the nuclear reactors at the plant are still out of control.

The accident at the Fukushima plant is very different from the Chernobyl nuclear crisis. The Chernobyl accident occurred while nuclear fission was under way but the Fukushima crisis took place after nuclear fission had been stopped.

The Fukushima accident is merely the result of the inability to remove the remaining heat from nuclear fuel. However, this remaining heat has caused such a serious crisis.

Tokyo Electric Power Co. (TEPCO), the operator of the plant, claims that it can place the power station under control if the external electric power grid to cool down the reactors is restored. TEPCO and the government's Nuclear and Industrial Safety Agency (NISA) share the view that the biggest lesson learned from the crisis at the Fukushima plant is that the loss of external power sources to cool down reactors can cause such a serious situation.

In the meantime, the public has learned another lesson from the accident -- how much damage can be caused by radioactive waste generated at nuclear power plants and the difficulties in bringing such troubled power stations under control. These issues had been common knowledge among those opposing nuclear power plants, but only became widely known to the public following the accident.

A documentary film titled, "Into Eternity," about a final radioactive waste burial facility in Finland called "Onkalo," is now being screened in Japan. It was released following the crisis without any prior advertising, but theaters where the film is being shown are full almost every day -- a far stronger reaction than its distributor had expected.

Onkalo is the only final radioactive waste disposal facility under construction in the world. Finland, which relies heavily on Russia for energy, needs nuclear power plants, and public consensus has been formed on the need to build a permanent nuclear waste burial site.

However, it will take 100,000 years before high-level radioactive waste becomes harmless. No structure has lasted for such a long period. No one can guarantee that the burial site will never be damaged by war, crustal changes or floods.

Moreover, the advancement of civilization and languages hundreds of years into the future is beyond people's imagination. The film raises questions on how people can tell their children and grandchildren about the risks that buried radioactive waste poses to the environment and whether the project is feasible or not.

Japan is pursuing a nuclear fuel cycle and a method for the final treatment of waste generated in that process, but has been unable to draw a clear roadmap toward that end. Japan is far more irresponsible than Finland in that its prospects for treating radioactive waste are unclear. Still, it has been generating a massive amount of nuclear waste. One cannot help but wonder whether Japan's practice is justifiable.

It is true that Prime Minister Naoto Kan's announcement that the government would ask Chubu Electric Power Co. to stop operating the Hamaoka plant came very suddenly. Some political analysts describe

Kan's actions as a populist performance while others call it a surprise move aimed at containing his political foes. However, these comments fail to get to the heart of the issue.

The point here is the tug-of-war between those who aim to continue generating and using electric power by all means and those who are attempting to change the trend of the times.

Everybody knows it would be unrealistic to immediately stop all nuclear power plants. Nevertheless, it is unjustifiable to demand that the operation of the Hamaoka Nuclear Power Plant continues because there are also other dangerous nuclear power stations in Japan. The operation of all other dangerous nuclear power plants should be restricted from a mid-term perspective.

It is a battle between the common sense of those who look straight at the crisis in Fukushima Prefecture and review Japan's reliance on nuclear power generation and the outdated thinking of those who disregard the plight of Fukushima residents and want to continue the current energy policy merely by force of habit. (By Takao Yamada, Expert Senior Writer)

Gov't, TEPCO in uphill battle to contain Fukushima reactors, set to review roadmap

Two months after the outbreak of the crisis at the Fukushima No. 1 Nuclear Power Plant, the government and Tokyo Electric Power Co. (TEPCO) are still fighting an uphill battle to contain overheating nuclear reactors and are likely to review their roadmap that seeks to put the reactors under control within six to nine months.

The government and TEPCO, the operator of the crippled nuclear plant, are set to review the roadmap on May 17, a month after it was unveiled. "Although we have been making progress little by little, we must not relax our efforts," said Goshi Hosono, secretary-general of the government joint task force.

Of all the reactors at the nuclear complex, the biggest progress in restoration work has been made at the No. 1 reactor. On May 10, work to set a water-level gauge in the reactor pressure vessel was completed. On May 11, the pressure gauge in the reactor was due to be adjusted. Preparations have been underway to install a recycle cooling system designed to cool down the reactor in a stable manner.

But many obstacles lie ahead. A high level of radiation -- 600 to 700 millisieverts per hour -- was detected in some part of the reactor building on May 9. That could force a review of the work schedule.

At the No. 2 reactor, water contaminated with high levels of radiation gathering in the basement of the turbine building is standing in the way of restoration efforts. Efforts have been made to remove the contaminated water, but the water level has not dropped sufficiently.

At the No. 3 reactor that sustained the heaviest damage, the temperature in the pressure vessel was rising. Although more water was injected into the vessel, the temperature has not dropped sufficiently.

The reactor building of the No. 4 reactor was destroyed by explosions. TEPCO is to set up a structure to support the pool from underneath to keep it sound.

Shojiro Matsuura, former head of the Nuclear Safety Commission, said at the Japan National Press Club that workers wearing airtight protective gear could come down with heat stroke in summer. He suggested that it was an urgent task to improve the work environment and set up a well-developed medical care system for emergency workers.

Radiation in soil near troubled Japan nuclear plant exceeds Chernobyl evacuation level

The levels of radiation accumulated in soil near the crippled nuclear power plant in northeastern Japan far exceeded the level of radiation the then-Soviet Union had used as a criterion for urging people to evacuate at the time of the 1986 Chernobyl nuclear disaster, threatening to plague local residents for a lengthy period.

Using aircraft, the Ministry of Education, Culture, Sports, Science and Technology checked the cesium-137 (half life of about 30 years) and cesium-134 (half life of about two years) accumulated in soil in collaboration with the U.S. Department of Energy in April.

Cesium-137 that has longer effects, ranging from 3 million to 14.7 million becquerels per square meter, was detected in Namie, Futaba, Minamisoma, Iitate and Katsurao, northwest of the Fukushima No. 1 Nuclear Power Plant, in Fukushima Prefecture. **The levels far exceeded 550,000 becquerels per square meter, the level the then-Soviet Union had used as a criterion for urging people to evacuate at the time of the 1986 Chernobyl nuclear disaster.**

Based on recommendations from the International Commission on Radiological Protection (ICRP), **the Japanese government used 20 millisieverts per year of radiation in the atmosphere as the criterion to designate evacuation areas in the wake of the nuclear accident** in Fukushima. Therefore, there are areas that have not been designated as evacuation zones although they have larger amounts of accumulated radiation.

The Ministry of Education, Culture, Sports, Science and Technology says, "Radioactive substances in soil do not enter human bodies immediately." On the other hand, when authorities try to decide whether to allow local residents to return to their homes or resume farming, levels of soil contamination could be one of the hot topics of debate.

Hiromi Yamazawa, professor of environmental radiology at Nagoya University, said, "The problem with soil contamination is external exposure through gamma rays emitted from cesium adhered to soil." He said that replacing soil with non-contaminated soil is an effective way of reducing the concentration of radiation. He also said, "Replacing soil in lower layers with that from upper layers is also effective."

EU divided over nuclear plants' resistance to attack

By [Pete Harrison](http://www.reuters.com/article/2011/05/11/us-eu-energy-nuclear-idUSTRE74A1NZ20110511) <http://www.reuters.com/article/2011/05/11/us-eu-energy-nuclear-idUSTRE74A1NZ20110511>

BRUSSELS | Wed May 11, 2011 7:49am EDT

(Reuters) - Europe's nuclear safety tests should be strengthened to include man-made crises, such as terrorist attacks or airplane crashes, European Commission President Jose Manuel Barroso said on Wednesday.

European leaders agreed in March to subject Europe's 143 reactors to "stress tests," to guard against disasters such as the one at Japan's stricken Fukushima plant.

But since then, a dispute has broken out between EU energy commissioner Guenther Oettinger, who wants the tests as wide-ranging as possible, and the French regulator, which opposes the inclusion of man-made scenarios.

Barroso threw his weight behind Oettinger on Wednesday, aiming to put an end to the dispute ahead of a meeting of the European Nuclear Safety Regulators Group (ENSREG) on Thursday, which will aim to agree methodology for the tests.

"These tests should be comprehensive and include the widest range of scenarios, natural and man-made, focusing on their possible impact on the plants' functioning systems," Barroso said in a statement. "I hope this can be agreed tomorrow."

"I will also push for the strengthening of the international legal framework governing nuclear safety, in particular the Nuclear Safety Convention and the Convention on Early Notification of a Nuclear Accident," Barroso added.

Those who oppose testing nuclear plants for their resilience to terrorist attack say the test might reveal weaknesses that terrorists would be quick to exploit, but Oettinger's spokeswoman said there was room for confidentiality.

"It is important that citizens know what we're doing and what the results of our stress tests are, but clearly...there's some information in this area which cannot be published, and the Commissioner said he was willing to compromise on that issue," Marlene Holzner told reporters.

Although the European Commission is trying to extend its reach into a region it has never regulated before, it still does not have powers to close unsafe reactors, and any such move would likely result from a government decision or public pressure.

"The stress test is in any case voluntary, because the European Commission, although it has a mandate to develop the stress tests, it does not have a mandate to force a member state to do the stress tests or to shut down a nuclear power plant," said Holzner.

TEPCO finds another leak of radioactive water into sea

TOKYO, May 11, Kyodo

Tokyo Electric Power Co. said Wednesday it had detected another leak of highly contaminated radioactive water into the sea near the Fukushima Daiichi nuclear power plant but was able to stop the flow.

Edano offers apologies over new radioactive water leak into sea

TOKYO, May 12, Kyodo

Chief Cabinet Secretary Yukio Edano said Thursday that a new leak of radioactive water into the sea from the troubled Fukushima Daiichi nuclear power plant was "very deplorable" and offered his apologies to neighboring countries and others who may be affected.

"I apologize for again causing worries and troubles to local residents, those in the fishing industry and neighboring nations," the top government spokesman told a news conference, a day after plant operator Tokyo Electric Power Co. announced the leak and said it was able to stop the flow.

The utility said highly contaminated radioactive water had leaked into the sea from a pit close to a seawater intake for the No. 3 reactor, after a similar case was detected last month near the No. 2 reactor of the Fukushima plant, which has been crippled by the devastating March 11 earthquake and tsunami.

Nuclear fuel at Fukushima No. 1 unit melted after full exposure

TOKYO, May 12, Kyodo

Water inside the troubled No. 1 reactor of the Fukushima Daiichi nuclear power plant was at an unexpectedly low level, not enough to cover the nuclear fuel, hinting that a large part of the fuel melted after being fully exposed, Tokyo Electric Power Co. said Thursday based on data obtained by adjusted gauges.

But the plant operator said the water at the bottom of the reactor pressure vessel holding the fuel is keeping the melted fuel cool, assuring that the company is succeeding in preventing the reactor's fuel from overheating by injecting water from outside.

Based on the latest data after workers adjusted gauges for measuring the water level at the reactor, water could not be confirmed inside the pressure vessel at a point 5 meters below where the top of the 4-meter-long fuel rods normally are, according to the utility also known as TEPCO.

Nuclear fuel at Fukushima No. 1 unit melted after full exposure

TOKYO (Kyodo) -- Water inside the troubled No. 1 reactor of the Fukushima Daiichi nuclear power plant was at an unexpectedly low level, not enough to cover the nuclear fuel, hinting that a large part of the fuel melted after being fully exposed, Tokyo Electric Power Co. said Thursday based on data obtained by adjusted gauges.

But the plant operator said the water at the bottom of the reactor pressure vessel holding the fuel is keeping the melted fuel cool, assuring that the company is succeeding in preventing the reactor's fuel from overheating by injecting water from outside.

Based on the latest data after workers adjusted gauges for measuring the water level at the reactor, water could not be confirmed inside the pressure vessel at a point 5 meters below where the top of the 4-meter-long fuel rods normally are, according to the utility also known as TEPCO.

The water level is far lower than earlier thought. Measurements taken before the gauge adjustment indicated that about 1.5 to 1.7 meters of the fuel rods were exposed and not submerged in water.

Still, the surface temperature of the pressure vessel was relatively low, measuring between 100 C and 120 C.

The utility had earlier estimated that 55 percent of the reactor core at the No. 1 unit has been damaged. It is unknown how much fuel melted and dropped to the bottom, but the fuel is unlikely to be at its original position.

TEPCO has been trying to check the levels of water inside the No. 1 reactor's pressure vessel and the outer primary container so that it can move ahead with a plan to flood the container with water up to the level above the fuel and create a system to stably keep the fuel cool.

But the latest finding on the situation inside the unit -- one of the six at the plant crippled by the March 11 massive quake and tsunami -- suggests that **a significant amount of the water injected into the reactor core to keep the fuel cool as an emergency measure was leaking out to the primary container.**

A TEPCO official said the company will review its plan to flood the primary container up to the level above the fuel.

Hidehiko Nishiyama, a spokesman for the government's Nuclear and Industrial Safety Agency, said even if the container is not flooded with water, creating a system that would enable coolant to circulate

around the reactor is possible by using the water that now exists inside the vessel and primary container.

TEPCO finds highly radioactive water leaked into Pacific Ocean

Tokyo Electric Power Co. (TEPCO) said on May 11 that it had discovered highly radioactive water was flowing into the ocean near the Fukushima No. 1 Nuclear Power Plant and swiftly moved to stop the flow.

TEPCO, the operator of the crippled nuclear power plant in northeastern Japan, said the highly toxic radioactive water was leaked into the ocean after flowing into a concrete hole called a "pit" near a seawater intake for the No. 3 reactor. **It is not clear when the water started flowing into the sea**, but the utility filled the pit with concrete to stop the water from flowing into the ocean on the afternoon of May 11. In a similar case, highly contaminated water had flowed from the seawater intake of the No. 2 reactor into the ocean in April.

According to TEPCO, when a worker was filling a tunnel for the No. 3 reactor, he found water flowing into the 2.3-meter-deep pit near the seawater intake.

The water in the pit contained a total of about 80,000 becquerels of radiation -- 37,000 becquerels of cesium-134, 620,000 times the legal limit for seawater and 39,000 becquerels of cesium-137, about 430,000 times the legal limit.

More than 80,000 metric tons of contaminated water is believed to be gathered in the concrete tunnels that house electric cables as well as in turbine buildings for the No. 1, 2, 3 and 4 reactors. Work has been underway to remove the water from the No. 2 reactor first. TEPCO believes that the contaminated water found on May 11 had come from a tunnel of the No. 3 reactor, as was the case for the No. 2 reactor in April.

Nuclear fuel at Fukushima No. 1 unit melted after full exposure

TOKYO, May 12, Kyodo

Tokyo Electric Power Co., the operator of the crippled Fukushima Daiichi nuclear power plant, revealed Thursday that **holes had been created by melted nuclear fuel at the bottom of the No. 1 reactor's pressure vessel.**

The company said it has found multiple holes adding up to several centimeters in welded piping. Earlier in the day, it said the amount of water inside the troubled reactor was unexpectedly low -- not enough to cover the nuclear fuel -- hinting that a large part of the fuel melted after being fully exposed.

The finding is raising concerns that the company will face difficulty achieving its plan to bring the damaged reactors to a stable condition known as a "cold shutdown" in about six to nine months, observers said.

May 12, 2011

Disaster Plan Problems Found at U.S. Nuclear Plants (NYT)

By [MATTHEW L. WALD](#)

ROCKVILLE, Md. — Despite repeated assurances that American nuclear plants are better equipped to deal with natural disasters than their counterparts in Japan, regulators said Thursday that **recent inspections had found serious problems with some emergency equipment that would have made it unusable in an accident.**

In addition, the staff of the [Nuclear Regulatory Commission](#) acknowledged that the agency's current regulations and disaster plans **did not give enough consideration to two factors that had greatly contributed to the continuing Fukushima Daiichi crisis in Japan: simultaneous problems at more than one reactor and a natural disaster that disrupts roads, electricity and other infrastructure surrounding a plant.**

The briefing was part of a review requested by the commissioners to evaluate the vulnerability of American reactors to severe natural disasters like the ones that hit the Japanese plant in March.

Marty Virgilio, the deputy executive director of the agency, told the five commissioners that inspectors checked a sample of equipment at all 104 reactors and found problems at less than a third of them. The problems included pumps that would not start or, if they did, did not put out the required amount of water; equipment that was supposed to be set aside for emergencies but was being used in other parts of the plants; emergency equipment that would be needed in case of flood stored in places that could be flooded; and insufficient diesel on hand to run backup systems.

Many of the emergency systems were put in place after the Sept. 11, 2001, terrorist attacks.

Officials said the problems that had been found were addressed immediately but not everything had been inspected. Mr. Virgilio said he expected to have a fuller picture soon.

He said an entire category of new procedures, called "severe accident mitigation guidelines," had been adopted **voluntarily** by the nuclear industry and thus was not subject to commission rules.

R. William Borchardt, the commission's chief staff official, said some of the preparations for severe accidents "don't have the same kind of regulatory pedigree" as the equipment in the original plant design.

The two-hour briefing given to the five-member commission was an early assessment, 30 days into a 90-day review being conducted by an N.R.C. task force.

Charlie Miller, the staff member leading the effort, said the staff was considering “enhancements” to its disaster plans and procedures. But as laid out by the staff, some of the changes under consideration could be far-reaching.

For example, the N.R.C. now looks at how well a plant’s design can handle a problem at just one reactor, even if there is more than one reactor at the site.

“You have to take a step back and consider what would happen if you had multiple units affected by some ‘beyond design basis’ events,” Mr. Miller said.

Another problem, staff members acknowledged, is that they have never paid much attention to the issues posed by handling an emergency when there is widespread damage to surrounding roads, power systems and communications links. In the past, the commission has explicitly rejected the notion that it should consider such combined events when reviewing a plant’s safety preparations.

Simultaneous with the commission’s meeting, Representative Edward J. Markey, a Massachusetts Democrat, released a report arguing that a variety of other shortcomings existed at nuclear plants, including the frequent failure of emergency diesel generators, which are essential to plant safety if the power grid goes down. He also criticized the commission for not requiring plants to have a backup power source for spent fuel pools while the reactor is shut for maintenance or refueling.

The Fukushima accident has cast new attention on spent fuel pools; the reason the United States government recommended that Americans stay 50 miles from the plant was damage to the spent fuel pool of Fukushima’s Unit 4, a reactor that was shut down before the March 11 earthquake and tsunami.

Mr. Markey pointed out that in the last eight years, the commission had received 69 reports of inoperable diesel generators at 33 plants, with six of those generators out for more than a month. The diesels provide power for water pumps that allow removal of “decay heat,” the heat that fuel generates even after a reactor shuts down. The Fukushima plants shut down successfully but decay heat wrecked their cores.

The N.R.C. said it was aware of the reports. But on Wednesday, attention was called to that problem by the Institute of Nuclear Power Operations, an industry group formed after the Three Mile Island accident in 1979 to provide peer-to-peer safety reviews. That group said one of the few safety measures that was getting worse was the reliability of diesel generators.

Mr. Markey also complained that the commission had allowed some plant operators to remove equipment that eliminates hydrogen produced by overheating fuel. In addition, there is no requirement for equipment to remove hydrogen in the rooms where spent fuel is stored; the building surrounding Fukushima Unit 4 was destroyed by the explosion of hydrogen that came from the spent fuel pool.

Commission officials said they were reviewing their previous decision to permit very heavy loading of the spent fuel pools. Thinning them out would reduce the amount of heat production that had to be dealt with in case of a severe accident, they said.

Nuclear fuel at Fukushima No. 1 unit melted after full exposure

TOKYO (Kyodo) -- Tokyo Electric Power Co., the operator of the crippled Fukushima Daiichi nuclear power plant, revealed Thursday that holes had been created by melted nuclear fuel at the bottom of the No. 1 reactor's pressure vessel.

The company said it has found multiple holes adding up to several centimeters in welded piping. Earlier in the day, it said the amount of water inside the troubled reactor was unexpectedly low -- not enough to cover the nuclear fuel -- hinting that a large part of the fuel melted after being fully exposed.

The finding is raising concerns that the company will face difficulty achieving its plan to bring the damaged reactors to a stable condition known as a "cold shutdown" in about six to nine months, observers said.

But the utility, known as TEPCO, noted that water at the bottom of the reactor pressure vessel holding the fuel is keeping the melted fuel cool, indicating that the company is succeeding in preventing the reactor's fuel from overheating by injecting water from outside.

Layout of cooling systems at the Fukushima No. 1 Nuclear Power Plant. (Mainichi)

Based on the latest data after workers adjusted gauges for measuring the water level at the reactor, water could not be confirmed inside the pressure vessel at a point 5 meters below the top of the 4-meter-long fuel rods when they are in their usual position, according to TEPCO.

The water level is far lower than earlier thought. Measurements taken before the gauge adjustment indicated that about 1.5 to 1.7 meters of the fuel rods were exposed and not submerged in water.

Still, the surface temperature of the pressure vessel was relatively low, measuring between 100 C and 120 C, allowing a TEPCO official to say, "We've been successful in cooling (the fuel rods with water)."

The utility had earlier estimated that 55 percent of the reactor core at the No. 1 unit has been damaged. It is unknown how much fuel melted and dropped to the bottom, but the fuel is unlikely to be in its original position.

TEPCO has been trying to check the levels of water inside the No. 1 reactor's pressure vessel and the outer primary container so that it can move ahead with a plan to flood the container with water up to the level above the fuel and create a system to stably keep the fuel cool.

But the latest finding regarding the situation inside the unit -- one of six at the plant crippled by the massive March 11 quake and tsunami -- suggests that a significant amount of the water injected into the reactor core as an emergency measure to keep the fuel cool was leaking out to the primary container.

A TEPCO official said the company will review its plan and map out additional necessary measures to flood the primary container up to the level above the fuel by Tuesday.

Hidehiko Nishiyama, a spokesman for the government's Nuclear and Industrial Safety Agency, said even if the container is not flooded with water, creating a system that would enable coolant to circulate around the reactor is possible by using the water that now exists inside the vessel and primary container.

The review of the flooding plan will include injecting around 8 tons of water per hour to raise the water level in the container and changing the point for the water's removal to make way for the new water circulation system, according to sources familiar with the situation.

The utility will also check the No. 1 reactor vessel to detect from where water is leaking, they added.

TEPCO, however, could face difficulties in accomplishing such missions, considering that the radiation level is high at some locations inside the No. 1 reactor's building, observers said.

(Mainichi Japan) May 13, 2011

Melted nuclear fuel shows TEPCO's data lacks credibility

Melted nuclear fuel inside the No. 1 reactor of the crippled Fukushima No. 1 Nuclear Power Plant has been found at the bottom of the reactor's pressure vessel, indicating there is a likelihood of a hole up to several centimeters in it, plant operator Tokyo Electric Power Co. (TEPCO) announced.

Many fuel rods at the reactor are under water and in a stable condition. But TEPCO's failure to detect a massive leak of water and to accurately measure water levels is likely to force the utility to review a road map that calls for bringing the plant's damaged reactors to a stable condition, known as a "cold shutdown," in about six to nine months.

TEPCO concluded that a large portion of fuel had melted inside the pressure vessel after workers double-checked the amount of water and found the water level inside the No. 1 reactor to be very low. TEPCO measures the water level by checking the differential between about 5 meters above the top of the 4-meter-long fuel rods and about 1.5 meters from the bottom of the fuel rods.

TEPCO had initially announced that the water level was about 1.6 to 1.7 meters from the top of the fuel rods. But new data revealed that the water level was at a point more than 5 meters below the top of the fuel rods.

The temperature at the lower section of the pressure vessel stood at a reasonable 100 to 120 degrees, leading the utility to speculate that a large portion of the fuel rods had previously melted, sank to the bottom of the vessel and were cooled.

Hidehiko Nishiyama, a spokesman for the Nuclear and Industrial Safety Agency (NISA), said the latest data has more credibility than previous data.

But Tadashi Narabayashi, a professor of reactor engineering at Hokkaido University, said, "It is problematic that TEPCO kept releasing data as if the water gauges were functioning properly. I wonder what a road map based on such data really means."

He said that most fuel was probably at the bottom of the pressure vessel and is being cooled. He cited a possibility that equipment which drives the control rods and other devices is penetrating and probably damaging the bottom of the vessel.

TEPCO officials said at a news conference on the night of May 12 that the pressure vessel's bottom appeared to have a hole measuring a total of several centimeters from which water and the fuel were likely leaking.

The question remains when the fuel melted and sank to the bottom. Nuclear fuel starts melting at an extremely high 2,800 degrees Celsius.

Hisashi Ninokata, a professor of nuclear engineering at the Tokyo Institute of Technology, speculated that the nuclear fuel probably melted when the fuel rods emerged from water immediately after an explosion of high calorific value. He said the current volume of calorific value is low and the fuel above water can be cooled with steam.

In the 1979 Three Mile Island nuclear accident in which a core meltdown occurred in its Unit 2 reactor, it took the plant operator and U.S. authorities 14 years to clean up radiation due to the difficulty in removing the melted fuel rods.

Ninokata said, "This time, workers cooled the reactors with sea water and there is a fear that salt has accelerated the pressure vessel's corrosion and damaged the unit. There is also a possibility of the melted fuel and metal from the cover pipes being mixed and solidified, making efforts to remove them (to shut down the reactor) a challenging task."

NISA defines a fall of melted fuel rods to the bottom of a pressure vessel as a meltdown. TEPCO acknowledged that it is a meltdown if the fuel rods are not in their original form.

Haruki Madarame, chairman of the Nuclear Safety Commission of Japan, said at a news conference on May 12, "It was not surprising because we predicted a melting of the fuel rods at an early stage. We don't think all of the fuel rods are under water judging from temperatures inside the pressure vessel. We want to do more analysis."

Sewage plants in Fukushima perplexed over how to dispose of highly radioactive sludge

Highly radioactive sludge found at sewage plants in Fukushima Prefecture will be temporarily kept at those plants, the central government has announced.

The move came after high levels of radioactive cesium were detected in sludge and other waste material at sewage plants in Fukushima Prefecture -- home to the disaster-crippled Fukushima No. 1 Nuclear Power Plant.

On May 12, the government announced that highly radioactive sludge will be tentatively kept at sewage plants in the prefecture, while sludge with relatively low-level radiation could be recycled into cement and other material.

While highly-radioactive sludge will be treated in the same way as radioactive waste for the time being, no plans for the final disposal of such sludge were presented. It will also be difficult to promote the recycling of sludge with high-level radiation contamination. Since relevant laws and regulations do not cover highly-radioactive sludge at sewage plants, the government faces serious challenges in handling the issue.

According to the announcement, sludge with radioactivity levels of over 100,000 becquerels per kilogram should preferably be incinerated and melted in Fukushima Prefecture before being kept at sewage plants. Ash generated through sludge incineration should be contained in metal barrels to prevent it from scattering. Sludge with radioactivity levels of under 100,000 becquerels per kilogram can be temporarily kept at sewage plants and controlled disposal sites, with radioactivity monitoring required.

"Radioactive sludge should be treated in the same way as radioactive waste," said an official with the Cabinet Office's Nuclear Disaster Countermeasures Headquarters, adding, "We will look into how to ultimately dispose of it later."

Sludge with radioactivity levels of under 1,000 becquerels per kilogram can be recycled into cement and other material if the levels can be reduced to under 100 becquerels through mixture with other materials and dilution.

"The volume of radioactive sludge should be reduced as much as possible through recycling," said an official with the Ministry of Land, Infrastructure, Transport and Tourism, adding that the recycling of such sludge into fertilizer should be withheld for the time being.

The government also announced that safety standards for workers at sewage plants should be applied in accordance with the Ordinance on the Prevention of Ionizing Radiation Hazards, which is administered by the Ministry of Health, Labor and Welfare.

The ordinance mandates operators to set up controlled areas and control radiation doses if radiation levels in the air at workplaces are expected to exceed 1.3 millisieverts in three months. However, since the ordinance does not presume cases in which private operators transport radioactive sludge, the government cannot obligate forwarding agents to take the abovementioned measures.

On May 1, the Fukushima Prefectural Government announced that 334,000 becquerels per kilogram of radioactive cesium was detected in molten slag **after** sludge was processed with high heat at a purification center in Koriyama, Fukushima Prefecture. The finding was followed by the detection of radioactive cesium in sludge at 15 other sewage plants in the prefecture, as well as at one sewage treatment facility in Tochigi Prefecture, one in Ibaraki Prefecture, three in Gunma Prefecture and one in Niigata Prefecture. The Kanagawa Prefectural Government announced on May 12 that cesium was detected in sludge at four sewage plants in the prefecture, while the Tokyo Metropolitan Government disclosed the same day that up to 24,000 becquerels of radioactivity was detected in sludge incineration ash at three sewage plants in the capital.

Reactor 1 in worse shape than thought

Cracks suspected in containment after fuel rods found fully exposed

By KAZUAKI NAGATA <http://search.japantimes.co.jp/print/nn20110513a1.html>

Staff writer

Tokyo Electric Power Co. said Thursday that the water level in the No. 1 reactor's pressure vessel at the Fukushima No. 1 power plant is much lower than thought and that some of the fuel rods have melted and sunk to its bottom.

But Tepco also said the temperature in the pressure vessel has been kept at around 100 to 120 degrees, which is cool enough to keep the reactor safe, for now.

The low water level, however, indicates that the pressure vessel could have holes or cracks through which radioactive water is leaking.

Tepco's latest discoveries were found after workers entered the main building, where they were finally able to check and fix water-level indicators damaged when the March 11 monster earthquake and tsunami crippled the nuclear power plant.

The workers also learned that the water in the containment vessel, which Tepco has kept spraying to cool down the pressure vessel from the outside, is also much lower than earlier believed. There might be some holes or cracks in the vessel or components connected to it, Tepco said.

Any holes or cracks in the pressure and containment vessels are sure to make repair work more difficult.

The utility plans to keep cooling the reactor's core by attaching air-cooling machines that will recirculate the water inside the containment vessel.

Tepco has poured about 10,000 cu. meters of water into the containment vessel so far. But only about 7,500 cu. meters should be necessary to cool the fuel rods if a way can be found to reuse the water instead of letting it flow away.

"We're not sure how much of the fuel rods fell down to the bottom and in what form, but the temperature shows that they are being cooled," Tepco spokesman Junichi Matsumoto said at a news conference.

On March 12, reactor No. 1 suffered a hydrogen explosion after the fuel rods were fully exposed for hours and generated hydrogen, which reacted violently with oxygen.

But Matsumoto said Tepco believes such an explosion at this time is unlikely because nitrogen has already been poured inside the containment vessel to purge explosive gases.

Matsumoto also said that, considering the situation with the No. 1 reactor, the water level data from reactors 2 and 3 may not be credible.

Tadashi Narabayashi, a professor of reactor engineering at Hokkaido University, also said it is likely that the melted fuel rods are being cooled with coolant water at the bottom of the pressure vessel.

According to Narabayashi, the zirconium encasing the fuel rods becomes weak and brittle when it is fully exposed to oxygen and then covered with cold water again.

According to Tepco, the water-level indicators of the pressure vessel had indicated the water surface was about 1.65 meters below the top of the fuel rods. But as of Thursday morning the reading was more than 5 meters below the top. The fuel rods, if undamaged, are only 4.5 meters in height.

Although the water is leaking from somewhere in the pressure vessel, Tepco officials don't believe the melted fuel has penetrated the bottom of the pressure vessel and dropped into the containment vessel below, given that the thermometer placed at the bottom of the pressure vessel is still working. If a big chunk was missing, it would malfunction, Tepco said.

There are actually no tools specially designed to check the water level in the containment vessel, but Tepco said it made estimates based on other factors, including the pressure in the containment vessel.

Contaminated nuke plant workers going back on job as safety regs go by wayside

The badly damaged building housing the Fukushima No. 1 Nuclear Power Plant's No. 1 reactor is pictured in this photo provided by a worker at the plant.

Safety standards for workers at the tsunami-hit nuclear power plant in Fukushima Prefecture have been relaxed without any scrutiny, forcing workers to do their jobs without being completely decontaminated, it has emerged.

Workers who are struggling to get the Tokyo Electric Power Co. (TEPCO)-operated Fukushima No. 1 Nuclear Power Plant under control as well as experts have expressed grave concern about possible health hazards.

Radiation levels on the premises of the power station remain high, with part of the ruins of its No. 3 reactor building -- badly damaged by a hydrogen explosion -- emitting 900 millisieverts of radiation per hour.

Safety regulations dictate that when it is estimated workers will be exposed to more than 1 millisievert of radiation per day at a nuclear power plant, companies contracted by the plant operator must submit a

work plan specifying the anticipated radiation levels to the local labor standards inspection office, get a receipt stamp and submit a copy of the document to the plant operator.

Some contractors then hand copies of the document to their subcontractors as a special permit to perform the work.

An employee of one of the subcontractors at Fukushima plant said he worked there without such a special permit and was exposed to 1.3 millisieverts of radiation over a 2 1/2-hour period. Subsequent screening detected radioactive substances on the back of the employee's head and neck, as well as those of about 10 co-workers.

They washed with special shampoo at the nuclear crisis operations center about 20 kilometers away from the plant. **However, three of them were unable to completely decontaminate themselves. They tried again at a TEPCO facility but failed to completely remove radioactive substances from their bodies. TEPCO subsequently issued a certificate specifying the areas of their bodies contaminated with radioactive material, and they returned to work.**

In cases where radioactive substances are detected on workers' bodies, their employers are required to submit a report detailing the work they performed and how they were contaminated to the original contractor, which in turn must notify TEPCO.

However, the workers' subcontractor has neither submitted such a report to the original contractor nor been instructed by the contractor or TEPCO to do so. The employee has pointed out that the safety regulations have been eased without any scrutiny amid the ongoing crisis.

"Both TEPCO and the original contractor appear to be thinking it's natural that we're contaminated with radioactive substances, considering our working environment," he lamented.

"Many of us are eager to help get the plant under control, and think we can't avoid being contaminated. But frankly speaking, we're concerned," he added.

TEPCO said the certificate specifying the areas of workers' bodies contaminated is issued if high levels of radiation are detected during screening, but claimed that such workers are completely decontaminated before returning to work.

TEPCO concealed radiation data before explosion at No. 3 reactor

2011/05/14 <http://www.asahi.com/english/TKY201105130370.html>

Debris litters the west part of the first floor at the No. 3 reactor building. (Provided by Tokyo Electric Power Co.)

Tokyo Electric Power Co. concealed data showing spikes in radiation levels at the Fukushima No. 1 nuclear power plant in March, one day before a hydrogen explosion injured seven workers.

The Asahi Shimbun obtained a 100-page internal TEPCO report containing minute-to-minute data on radiation levels at the plant as well as pressure and water levels inside the No. 3 reactor from March 11 to April 30.

The data has never been released by the company that operates the stricken plant.

The unpublished information shows that at 1:17 p.m. on March 13, 300 millisieverts of radiation per hour was detected inside a double-entry door at the No. 3 reactor building. At 2:31 p.m., the radiation level was measured at 300 millisieverts or higher per hour to the north of the door.

Both levels were well above the upper limit of 250 millisieverts for an entire year under the plant's safety standards for workers. But the workers who were trying to bring the situation under control at the plant were not informed of the levels.

When the Great East Japan Earthquake struck on March 11, the No. 1, No. 2 and No. 3 reactors all automatically shut down. But the tsunami crippled the emergency generators, leading to a total power failure that prevented the cooling systems from functioning.

The TEPCO data also showed high levels of hydrogen may be emitting from the damaged core of the No. 3 reactor on March 13, when TEPCO started injecting seawater to cool the reactor.

The following day around 11 a.m., a hydrogen explosion destroyed the upper part of the No. 3 reactor building. Seven TEPCO workers were injured in the blast.

TEPCO's public relations department said the company has informed the public that significant levels of radiation have been detected at the plant, but it disclose specific data after a thorough review of the figures is completed.

Keiji Miyazaki, professor emeritus of nuclear reactor engineering at Osaka University, criticized TEPCO's policy.

He said such important data should be immediately released to ensure the safety of the public and workers at the plant, especially in an emergency like the Fukushima nuclear accident.

Miyazaki said TEPCO's decision to conceal the data must be scrutinized.

Failure to release radiation data in the early stages of the crisis is said to have delayed the evacuations of communities near the plant.

Kiyoshi Sakurai, another nuclear power expert, said a thorough examination is needed not only on TEPCO's unpublished data, but also verbal communications of those involved, instructions issued by the central government and TEPCO, and the communication structure between management and workers at the plant.

Key nuclear facilities may have been damaged before tsunami

<http://mdn.mainichi.jp/mdnnews/news/20110515p2g00m0dm007000c.html>

TOKYO (Kyodo) -- Data taken at the Fukushima Daiichi nuclear power plant on the night of March 11 showing a high level of radiation at a reactor building suggest the possibility that key facilities there may have been damaged by the quake itself that day rather than tsunami-caused power loss that failed the reactor's cooling function, a utility source said Saturday.

The revelation may call for a review of preparedness against quakes at various nuclear power stations in Japan as they have primarily focused on securing auxiliary power supplies and embankment enhancement against tsunami after the Fukushima plant crisis, assuming that reactor facilities at the plant were unscathed by trembling.

On March 11, the power plant was shut down automatically just past 2:46 p.m. following the magnitude-9 quake. Within an hour, it was hit by at least two rounds of tsunami waves. The external power supply was then shut down, disabling the emergency core cooling system from injecting water at 4:36 p.m.

Prime Minister Naoto Kan declared the country's first state of nuclear emergency in the evening and residents near the plant were asked to evacuate.

Workers entered the No. 1 reactor building in the night to assess damage to the reactor but a few seconds later their dosimeter's alarm was triggered, according to the sources at Tokyo Electric Power Co. The building was believed to be filled with steam with high radiation dose, prompting the workers to evacuate.

Based on dosimeter readings, radiation was estimated at around 300 millisieverts per hour, according to the sources, a result suggesting a large amount of radioactive materials from nuclear fuel in the reactor was already released.

It has been thought that power loss failed the cooling system at the No. 1 reactor, releasing highly radioactive steam from the reactor pressure vessel.

This scenario assumes that pressure inside the reactor had built up and damaged piping and other facilities, a process that is thought to require a much longer time before such building is filled with steam.

A source at TEPCO admitted the possibility of key facilities having been compromised before the tsunami waves, saying, "The quake's trembling may have caused damage to the pressure vessel or pipes."

The Nuclear and Industrial Safety Agency has so far said the reactor withstood shaking but tsunami of an unexpected scale caused power loss, which led to an explosion.

On the night of March 11, TEPCO did not yet take the step of opening vents of the containment vessel to relieve pressure that was supposed to be rising, a move that it took in the morning the following day that led to the release of radioactive steam from the vessel.

Inside the No. 1 reactor, water level was falling from the night of March 11. TEPCO sprayed a large volume of water but failed to recover water level, leading to exposure of fuel and a meltdown of the reactor core.

Subsequently, zirconium, a metal covering fuel triggered a chemical reaction with steam, generating hydrogen and leading to the explosion at the reactor building at 3:36 p.m. on March 12.

en français:

Des installations clés de la centrale nucléaire n°1 de Fukushima auraient été endommagées par le séisme, avant le tsunami

Par **Liang Nin**, le 15/05/2011 à 13:39 © [Chine Nouvelle](#) (Xinhua)

Lors du [séisme](#) du 11 mars, des installations clés de la centrale [nucléaire](#) n°1 de Fukushima auraient été endommagées par les fortes secousses telluriques, avant même que le système de refroidissement du réacteur, affecté par la coupure d'électricité causée par le tsunami, ne cesse de fonctionner, a rapporté samedi l'agence de presse Kyodo, citant une source de Tepco, la compagnie exploitante de la centrale.

Selon les données recueillies le 11 mars au soir par les employés qui sont entrés dans le bâtiment abritant le réacteur n°1 de la centrale accidentée, le niveau de radiation atteignait 300 millisieverts par heure, ce qui suggère qu'une grande quantité de substances radioactives provenant des combustibles nucléaires du réacteur était en train de s'échapper.

Cette découverte pourrait amener à réviser les capacités de résistance des installations en cas de séismes dans les autres centrales nucléaires japonaises, où, suite à l'accident de Fukushima, l'on s'est essentiellement concentré sur la capacité des générateurs de secours à maintenir l'alimentation électrique en cas de défaillance externe ainsi que sur le renforcement des digues anti-tsunami, en supposant que les installations au sein des réacteurs à Fukushima n'avaient pas été endommagées lors du tremblement de terre.

Le 11 mars, la centrale [nucléaire](#) s'est automatiquement arrêtée à 14h46 heure locale suite au [séisme](#) de magnitude 9. Moins d'une heure plus tard, elle a été frappée par au moins deux énormes vagues successives lors du tsunami. L'alimentation externe en électricité a été interrompue, ce qui a empêché, dès 16h36 heure locale, le système d'urgence de refroidissement du cœur d'injecter de l'eau.

Selon l'hypothèse initiale, c'est l'arrêt de l'alimentation électrique qui a empêché le système de refroidissement du réacteur n°1 de fonctionner normalement, ce qui a abouti à la fuite de vapeur hautement radioactive de l'enceinte de confinement du réacteur.

Cependant, un responsable de Tepco a reconnu la possibilité que des installations clés aient été endommagées avant que les vagues du tsunami ne viennent déferler sur le site, déclarant que "les secousses du tremblement de terre pourraient avoir provoqué des dégâts au niveau de la cuve [cuve en acier entourant le cœur du réacteur] ou au niveau de certaines conduites", a rapporté Kyodo.

L'Agence japonaise de sûreté [nucléaire](#) et industrielle a jusqu'à présent affirmé que le réacteur avait bien résisté au tremblement de terre, mais que le tsunami d'une ampleur imprévue qui s'en était suivi avait entraîné la coupure d'électricité, qui avait abouti à une explosion au niveau du bâtiment externe abritant le réacteur n°1.

Trouble delayed cold shutdown of Hamaoka nuclear reactor

Sunday 15th May, 06:53 PM JST

SHIZUOKA —

Chubu Electric Power Co said Sunday that **cooling system trouble delayed the cold shutdown of the No. 5 reactor at its Hamaoka power plant** in Shizuoka Prefecture for about two hours earlier in the day, while ruling out any external release of radioactive substances.

Seawater leaked into a steam condenser at the reactor, which cools and turns steam from the turbines into water, apparently due to damage to its piping, prompting the utility to switch to another system to cool and stabilize the reactor and complete the work shortly past noon, it said.

The No. 5 unit was the last active nuclear reactor at the plant located in the Pacific coastal city of Omaezaki to come to a stable condition with an internal temperature below 100 C, the benchmark for cold shutdown.

The utility serving central Japan halted operation of the plant—its only nuclear facility located around 180 kilometers southwest of Tokyo—on Saturday, following an unprecedented government request due to fears of another nuclear disaster in the event of a large earthquake in the area, which lies on a major active fault line.

The ongoing nuclear crisis at Tokyo Electric Power Co's Fukushima Daiichi power plant on the Pacific coast around 220 km northeast of Tokyo was triggered by the devastating March 11 quake and tsunami.

The Nagoya-based firm said it had found Saturday evening, after a measuring instrument indicated abnormalities around 4:30 p.m., that **around 400 tons of seawater had flowed into the condenser of the No. 5 reactor**.

The water also found its way into the reactor, making it necessary to desalinate it, the company said.

At the plant, the No. 4 reactor was halted Friday and came to a stable condition the following day while the No. 3 reactor was already suspended for regular checks. The Nos. 1 and 2 reactors at the plant have been shut down for decommissioning.

In a related development, Katsuya Okada, secretary general of the ruling Democratic Party of Japan, said Sunday nuclear power plants that remain closed or were shut down after the March 11 earthquake and tsunami should be restarted provided that they meet tougher safety standards.

“It is an irrefutable fact that Japan cannot secure the electricity it needs unless it utilizes existing nuclear plants and those under construction,” he said, adding, “The public is now taking a more critical view concerning the safety of atomic energy, so revamping the existing safety standards should be a prerequisite (for continued use of nuclear facilities).”

Okada made the comments during a meeting with mayors of localities in Aomori Prefecture, where one nuclear power station is currently out of action and another is under construction.

Germany 'not satisfied' with nuclear fusion spending

VALENTINA POP

11.05.2011 @ 09:27 CET

EUOBSERVER / BERLIN - Germany has said it is unhappy with the "exorbitant" cost of the EU's international nuclear fusion project, Iter EU, and called for more transparency on spending.

"The bigger a science project is - and in Iter, Europe is not the only member - the more complicate its governance. **Iter is exorbitant**," Annette Schavan, Germany's education and research minister told journalists on Tuesday (10 May).

A detailed cutaway of the Iter, with hot plasma, in pink, in the centre. (Photo: ITER)

Schavan said that Berlin last year demanded a special taskforce to investigate the governance of the France-based nuclear fusion project, which aims to generate energy from fusing atoms, instead of splitting them as it is the case with the current nuclear technology (fission).

Apart from the EU - carrying the brunt of the cost (45 percent), the mega-project includes Russia, China, the US, India, Japan and South Korea contributing with nine percent of the cost, **expected to reach over €15 billion**. Supporters of the project say it will deliver to the world an essentially endless supply of cheap energy.

But the cost has tripled from its initial estimate in 2005, with Schavan noting that "science has a tendency to encourage politics to ask for more money."

"It is good for Europe to be present in such a project and Germany still supports it, but we need more transparency in its governance, more financial discipline. I am not satisfied today, one year later after the taskforce was put in place," she said.

The European Parliament last year refused to approve a proposal by the European Commission to reallocate €1.3 billion from the Union's unspent budget to cover a financing shortfall for the project.

The commission has re-cast its bid for the 2012 budget, pointing out that this is an international commitment the bloc cannot abandon and that construction is set to begin next year. A first debate in the parliament in April had Greens protesting against the project and pointing out that **it is to be built in a seismic area**, recalling the disaster of Fukushima, a nuclear fission plant.

Iter maintains that no comparisons can be made, since the technology is fundamentally different. [ah bon]

Yet radioactive materials will still be produced if the researchers manage to secure a safe reactor for the high-power reaction to take place.

Sebastien Balibar, a leading French nuclear physicist, has cast doubts that the EU-funded project will ever come into being: "We say that we will put the sun into a box. The idea is pretty. The problem is, we don't know how to make the box," he told the Wisconsin Scientist in 2006.

TEPCO admits nuclear meltdown occurred at Fukushima reactor 16 hours after quake

Tokyo Electric Power Co. (TEPCO) **admitted for the first time on May 15** that most of the fuel in one of its nuclear reactors at the Fukushima No. 1 Nuclear Power Plant had melted **only about 16 hours after the March 11 earthquake** struck a wide swath of northeastern Japan and triggered a devastating tsunami.

According to TEPCO, the operator of the crippled nuclear power plant, the emergency condenser designed to cool the steam inside the pressure vessel of the No. 1 reactor was working properly shortly after the magnitude-9.0 earthquake, but it lost its functions around 3:30 p.m. on March 11 when tsunami waves hit the reactor.

Based on provisional analysis of data on the reactor, the utility concluded that the water level in the pressure vessel began to drop rapidly immediately after the tsunami, and the top of the fuel began to be exposed above the water around 6 p.m. Around 7:30 p.m., the fuel was fully exposed above the water surface and overheated for more than 10 hours. At about 9 p.m., the temperature in the reactor core rose to 2,800 degrees Celsius, the melting point for fuel. At approximately 7:50 p.m., the upper part of the fuel started melting, and at around 6:50 a.m. on March 12, a meltdown occurred.

On the reason why it took over two months after the earthquake to reveal the information, TEPCO said it had only been able to start obtaining detailed data on the temperature and pressure in the reactor for analysis in early May.

Junichiro Matsumoto, a senior TEPCO official, said, **"Because there is similar damage to the fuel rods at the No. 2 and 3 reactors, the bottoms of their pressure vessels could also have been damaged."** He said the utility would carry out similar analysis on the two reactors.

Hiroaki Koide, professor of nuclear safety engineering at Kyoto University, was critical of TEPCO.

"They could have assumed that when the loss of power made it impossible to cool down the reactor, it would soon lead to a meltdown of the core. TEPCO's persistent explanation that the damage to the fuel had been limited turned out to be wrong," he said.

(Mainichi Japan) May 16, 2011

EDF to Rely on Seaside Reactors as Drought Cuts Water Levels

By Tara Patel - May 16, 2011 3:45 PM GMT+0200 <http://preview.bloomberg.com/news/2011-05-16/edf-to-rely-on-seaside-reactors-as-drought-cuts-water-levels-1-.html>

Electricite de France SA will limit planned maintenance at nuclear reactors near the [English Channel](#) and Atlantic Ocean as the driest spring in about 50 years reduces river water for cooling inland plants.

EDF, [Europe](#)'s biggest power generator, operates France's 58 nuclear reactors that provide about three quarters of the country's power needs. Most require river water for operations, prompting the utility and the country's nuclear safety watchdog to step up monitoring.

Measures being taken by the utility include the "limitation of summer outages in seaside nuclear plants," EDF said in a [presentation](#) last week. The dozen French reactors that rely on seawater for cooling include Gravelines, Penly, Paluel, Flamanville and Blayais.

EDF schedules planned refueling and maintenance sometimes years in advance to coincide with a greater need for base nuclear power during cold winter months and hot summer months. The utility was forced to reduce output at some riverside reactors during a 2003 heat wave that left 14,000 people dead.

"We have to pay attention to reactor operations. A decline in water flow and increase in temperatures have an impact on cooling," French Environment Minister Nathalie Kosciusko-Morizet said at a news conference today. "If the water flow becomes too low, a reactor will be halted."

Maintain Level

Swiss authorities would like to maintain the water level of Lake Geneva by adjusting flows into the Rhone River, she said, adding that this could affect French reactors.

The current dry spell, which has prompted water restrictions in some areas, hasn't had an impact on nuclear output, EDF spokeswoman Jill Coulombe said by telephone. French law requires plants to reduce output when water levels drop below a certain level or shut down if temperatures rise too high.

Dry conditions lowered EDF's hydroelectric power production by 2.1 terawatt-hours last quarter, EDF said in a May 12 [statement](#).

The availability of water for EDF power generation started to fall below average in the middle of January and remained through March below the minimum recorded over the past decade, according to last week's presentation.

On Record

[France](#) may have "one of the driest" months of May on record, Michele Blanchard, a researcher at forecaster Meteo France, said in an interview in Paris today. No significant rain is forecast for the next two weeks and temperatures will start rising.

France's nuclear safety watchdog is reviewing guidelines that would need to be followed in the event of a drought in the coming months, Andre-Claude Lacoste, head of the Autorite de Surete Nucleaire, said last week. Reactors that may be affected include those located on the Loire and Rhone Rivers, he said.

EDF will also carry out weekly "stress tests based on historical temperature models," as part of water management measures as well as "cautious" management of the water in dams, according to the presentation.

Hydroelectric reserves in France are 9 percentage points below the same week last year and 11 points lower than in 2009, according to data on the website of Reseau de Transport d'Electricite, a unit of EDF. France gets about 20 percent of its power capacity from running water through turbines.

Meltdown may have occurred also at Nos. 2, 3 reactors

TOKYO, May 16, Kyodo

An adviser to Prime Minister Naoto Kan said Monday that the operator of the Fukushima Daiichi nuclear power plant had failed to inject water into the Nos. 2 and 3 reactors for more than six hours after the March 11 massive earthquake and ensuing tsunami.

Goshi Hosono, tasked with handling the nuclear crisis, said at a press conference that Tokyo Electric Power Co. had not been able to cool down the reactors' cores due to loss of external power for a long time after the quake, acknowledging that fuel in the vessels might have largely melted "in the worst-case scenario."

But he added the utility, known as TEPCO, has been succeeding in preventing the reactor's fuel from overheating so far and reiterated the government will stick to the timetable set by the firm, which announced April 17 it aims to bring the crisis there under control in six to nine months.

Meltdown may have occurred also at Nos. 2, 3 reactors

TOKYO (Kyodo) -- An adviser to Prime Minister Naoto Kan said Monday that the operator of the Fukushima Daiichi nuclear power plant had failed to inject water into the Nos. 2 and 3 reactors for more than six hours after the March 11 massive earthquake and ensuing tsunami.

Goshi Hosono, tasked with handling the nuclear crisis, said at a press conference that Tokyo Electric Power Co. had not been able to cool down the reactors' cores due to loss of external power for a long time after the quake, acknowledging that fuel in the vessels might have largely melted "in the worst-case scenario."

But he added the utility, known as TEPCO, has been succeeding in preventing the reactor's fuel from overheating so far and reiterated the government will stick to the timetable set by the firm, which announced April 17 it aims to bring the crisis there under control in six to nine months.

His remarks came a day after TEPCO said a nuclear fuel meltdown at the No. 1 reactor is believed to have occurred around 16 hours after the devastating quake and tsunami crippled the plant's critical cooling systems.

TEPCO is slated to release on Tuesday an updated roadmap for bringing under control Japan's worst nuclear accident based on new information about the plant's condition.

Hosono has said that it has no choice but to abandon an initial plan to flood and cool the No. 1 reactor's containment vessel as holes have been created in the pressure vessel by the melted fuel.

The government will also unveil the same day its own version of a roadmap that will outline measures on how to deal comprehensively with the crisis amid growing discontent by lawmakers and the public over the government's handling of it.

TEPCO, meanwhile, said Monday it will start transferring highly radioactive water at the No. 3 reactor of the atomic power complex to a waste-disposing facility the following day to prevent it from leaking into the environment.

The move is believed to be essential to contain radiation leaks from the power station as well as to allow workers to get access to the damaged vessel, from which the contaminated water may be leaking to its adjacent turbine building and other places.

While such water previously found at the No. 2 reactor has been already stored in the facility, the utility has stepped up its efforts to set up equipment at the water-disposing facility to decontaminate the radioactive water so it can be reused to cool fuel in the vessels in the near future, company officials said.

Under a plan by TEPCO, a total of 4,000 tons of water is expected to be pumped out of the No. 3 reactor turbine building to the nuclear waste disposal facility by using hoses.

The utility has been injecting more water into the reactor than in the past to cool down its vessel as its temperature has been rising recently, pushing the level of water up there, the officials said.

The government's Nuclear and Industrial Safety Agency said it has already given the green light to TEPCO's plan.

The tainted water, the level of which has been rising by around 2 centimeters a day in the No. 3 reactor's turbine building, may be leaking into the sea, prodding the plant operator to remove it as soon as possible.

But TEPCO is also being forced to keep injecting sufficient quantities of water into the reactor as workers have been struggling to cool down its vessel stably.

The temperature inside the No. 3 reactor has been rising since the beginning of the month, topping 200 C on May 7, compared with around 90 C on May 1, TEPCO said.

While the temperature fell to 141.3 C on Monday morning, TEPCO remains vigilant as there is some skepticism about whether water has remained in the reactor, company officials said.

Radiation data from Japanese disaster starts to filter out

[Declan Butler](#)

Published March 17, 2011

Confidential data held by nuclear test ban organization emerging as key to monitoring Fukushima radiation.

Nature [revealed earlier](#) this week than an international agency set up to detect nuclear tests, the Comprehensive Nuclear-Test-Ban Treaty Organization ([CTBTO](#)), is transmitting detailed data on the spectrum of radionuclides and their levels in the air in and around Japan and the Asia-Pacific region to its member states each day, but that the CTBTO could not release these data to the public because it lacked a mandate to do so.

Now, at least one CTBTO member state, Austria, intends to make some of the data public in the form of summary reports and forecasts of global radiation spread.

Nature has also learned that initial CTBTO data suggest that a large meltdown at the Fukushima power plant has not yet occurred, although that assessment may change as more data flow in during the coming days. Lars-Erik De Geer, research director of the [Swedish Defence Research Institute](#) in Stockholm, which has access to the CTBTO data and uses it to provide the foreign ministry and other Swedish government departments with analyses, says that the data show high amounts of volatile radioactive isotopes, such as iodine and caesium, as well the noble gas xenon. But so far, the data show no high levels of the less volatile elements such as zirconium and barium that would signal that a large meltdown had taken place — elements that were released during the 1986 reactor explosion in Chernobyl in the Ukraine.

Rather, the data sit well, he says, with a scenario wherein the main release of radioactivity has come from the release of excess pressure in the containment vessels of affected reactors, and the subsequent explosion of the evacuated hydrogen-laden steam within the reactor buildings. The radioactive plume will spread around the hemisphere within weeks, he predicts, but the levels of radioactivity outside

Japan will not be dangerous. The levels in Japan itself, outside the immediate vicinity of the Fukushima power plant, "wouldn't scare me", he adds.

Watchful waiting

De Geer and other scientists are keenly awaiting the fresh data that they will receive from CTBTO over the next few days. Initial data from a station near Tokyo were corrupted because the collection filters used in the sensors were contaminated earlier this week during handling when a plume of radioactivity fanned over the station building, according to Gerhard Wotawa, a researcher at Austria's weather service, the Central Institute for Meteorology and Geodynamics in Vienna. That situation has now been resolved and better data are expected from tomorrow, he says.

The centre this week published [maps of radioactive spread](#) based on atmospheric transport models, which incorporate weather forecasts. (See this [animation](#) of the predicted course.) Given prevailing winds, plumes of low levels of radiation are expected to travel across the Pacific Ocean and reach the western seaboard of the United States by the end of the week. Stations in Russia are starting to pick up increases in radioactive noble gases, says Wotawa, and stations outside Japan are likely to start detecting higher radionuclides levels in the coming days.

The CTBTO data come from a worldwide network of radionuclide particulate monitoring stations operated by the Preparatory Commission of the CTBTO, a Vienna-based body set up to build a verification regime for a global ban on the testing of nuclear weapons, so that this network will be operational when enough of the organization's member states have ratified the treaty for it to enter force. The organization monitors radionuclide, seismic, hydroacoustic and infrasound characteristics at stations across the globe to check for the tell-tale signals of a nuclear bomb test.

[boxed-text](#)

Location of CTBTO's radionuclide monitoring stations in the Asia-Pacific region. Click for larger image.

Credit: CTBTO

The CTBTO has 60 radionuclide particulate monitoring stations in operation, and two of these are in Japan, near Tokyo, with dozens of others, often on islands, throughout the Asia-Pacific region (see map). It also has instruments to monitor noble gases, such as xenon. These stations monitor the air continuously, and so have extensive data on any radionuclides projected into the atmosphere during the ongoing nuclear disaster.

The data would be of enormous public interest as they would provide a far fuller picture of the extent and spread of any current or future radioactive release from the major Japanese nuclear accident now

under way. But although the data are being made available to member states and their radiation protection services, the CTBTO cannot make them public.

Worldwide web

The CTBTO does make available its hydroacoustic and seismic data — among the most reliable and rapid around — for the purposes of tsunami warnings, and indeed these data [contributed](#) to the rapid alerts issued by tsunami warning systems following the 9.0-magnitude earthquake. The agency's member states agreed to this after the 2004 Indian Ocean tsunami. But the CTBTO has no mandate for making radionuclide data publicly available for the purposes of monitoring nuclear accidents, because its member states have not yet agreed for it to have this role — although it does have a mandate to release radionuclide data on nuclear tests (see, for example, '[North Korea's ignoble blast](#)').

Yet its radionuclide network is also well adapted to monitoring levels of radiation in the fallout from nuclear accidents — it is still picking up radioactive caesium-137 (which has a 30-year half-life) from the 1986 Chernobyl reactor explosion in the Ukraine, for example — and its website lists such work as one of the [civil benefits](#) of its network of monitoring stations.

Each particulate monitoring station sends one γ -ray spectrum per day, a two-dimensional plot showing which radionuclides, and how much of each, occur in its sampling. Nuclear accidents produce a spectrum of radioactive fission products, including various radioisotopes of iodine, caesium and zirconium. The network can pick up all of them, says Lassina Zerbo, director of the CTBTO Preparatory Commission's International Data Centre Division in Vienna.

De Geer criticizes the secrecy surrounding CTBTO data. "For me it is absolutely clear: all this should be totally open," he says. "The CTBTO is a complicated organization; certain member states want all data to be classified, so they are not allowed to be given out," says De Geer, who was formerly head of the CTBTO's Radionuclide Development Unit. Even freeing the tsunami-relevant data "took years of discussion", he says.

He believes that the national laws of Sweden, a CTBTO member state, give it the right legally to "do what we want with the data", adding that the issue of the confidentiality of the data is nonetheless still a "grey zone". Wotawa likewise believes that Austria has the right to use the data, and says that his centre will be publishing CTBTO data in the daily updates of the Fukushima fallout that it is providing on its [website](#).

Zerbo says that the CTBTO's radionuclide monitoring service would be well placed to take on any international role in monitoring nuclear accidents for radiation protection purposes. "Japan and other countries have their own national radiation protection services, but where we could be useful is the worldwide nature of our monitoring network", he says. "We are the only truly worldwide radionuclide monitoring network." In a step towards that role, the CTBTO and the International Atomic Energy Agency in Vienna yesterday agreed to cooperate.

TEPCO documents reveal chaos at Fukushima nuke plant after quake, tsunami

If there is one word to describe events at the Fukushima No. 1 Nuclear Power Plant in the immediate aftermath of the March 11 quake and tsunami -- with cooling systems failing and the worst nuclear disaster since Chernobyl brewing in its reactors -- it would be "chaos."

That is the picture painted by documents released by Tokyo Electric Power Co. (TEPCO) on May 16 describing the situation at the plant in the hours after tsunami slammed into the coastal facility. Coming more than two months after the disaster, the TEPCO data will soon be dissected by a government committee set up to analyze the causes of the nuclear crisis and the actions taken by both the government and TEPCO to contain it.

"The power-source trucks (to supply the reactors with outside power) are stuck in traffic!"

"We've given up on venting operations (to lower reactor vessel pressure). The radiation is just too high."

These are just two of the TEPCO employee reports included in the documents, which also lay out the exact chronology of events at the plant as the disaster unfolded.

At exactly 46 minutes and 46 seconds past 2 p.m. on March 11 -- just after the magnitude 9.0 earthquake had struck off the northeast coast of Japan -- reactors No. 1-3 began emergency shut-down procedures (reactors No. 4-6 were not operating). However, as the reactors were shutting down, the plant log reveals workers were being bombarded with alarms for control rod insertions in each reactor, water level fluctuations, and other details of a nuclear plant swinging into crisis-response mode.

According to the TEPCO documents, the tsunami hit at about 3:30 p.m., cutting all power at the plant. In response, at about 5 p.m. TEPCO ordered power-source trucks to head to the plant from its branches nearby. However, "the trucks were unable to make progress due to road damage and traffic jams," a report included in the documents states. Unable to get the trucks to the Fukushima plant, at 6:20 p.m., TEPCO requested neighboring Tohoku Electric Power Co. to send some in their stead.

The Tohoku Electric trucks did not arrive at the plant until about 11 p.m., but faced with "the dark, pools of tsunami water, missing manhole covers on the road, and debris everywhere hindering progress," workers found hooking up the necessary power cables extremely difficult, according to a report from around dawn on March 12. Power was finally restored to the plant at about 3 p.m., but at 3:36 p.m. a massive hydrogen explosion in the No.1 reactor building destroyed the newly laid cables, cutting power once more.

Meanwhile, workers inside the plant were trying to vent the No. 1 reactor to relieve pressure building in the reactor vessel. Reports made as the crisis went on show workers tried to vent the reactor manually at about 9:15 p.m. on March 11 but soon had to stop, with an entry at about 9:30 p.m. stating, "We tried the operation onsite, but the radiation dose was so high we gave up." The venting operation was eventually completed, but not until 10:17 p.m.

What the workers were doing between 9:30 p.m. and 10:17 p.m., however, is not revealed in the TEPCO documents, and a TEPCO representative told reporters, "We don't know what kind of risk assessment led the workers to try again."

However, an entry for 9:51 p.m. in the plant duty log also released by TEPCO states: "No entry permitted" to the No. 1 reactor building due to high radiation -- an order that photos of memos on the plant's central control room whiteboard show came directly from TEPCO President Masataka Shimizu. The high radiation that led to the no-entry order furthermore lends support to the theory that a core meltdown began soon after the tsunami struck.

While much of the detail surrounding TEPCO's immediate response to the disaster is included in the documents, there is no record of the utility's communications with the Prime Minister's Office, leaving government-TEPCO interactions over critical decisions such as the venting operation and the use of sea water for cooling a mystery.

Cooling system of Fukushima plant's No. 1 reactor not functioning before tsunami

The No. 1 reactor's emergency cooling system at the Fukushima No. 1 Nuclear Power Plant was not functioning even before tsunami triggered by the March 11 earthquake struck the facility, according to initial data released on May 16 by Tokyo Electric Power Co. (TEPCO).

The emergency cooling system had previously been believed to be operating until the tsunami hit the No. 1 reactor. TEPCO had based the results of its analysis of how the cooling system stopped functioning -- which were released on May 15 -- on the assumption that the system was damaged by the tsunami.

TEPCO had also said prior to the release of analytical results on May 15 that the cooling system became inoperative due to the tsunami.

"Pressure inside the reactor suddenly dropped due to the cooling system. It probably was manually halted," plant operator TEPCO explained. As the tsunami neared the power plant, workers repeatedly tried to halt the cooling system, resulting in the loss of the system's capabilities.

The revelation is expected to figure importantly in an upcoming governmental probe of the cause of the accident.

TEPCO's newly released data, totaling about 2,900 pages, included various records from the No. 1 reactor, a log of warnings, the handover diaries by operators in the central control room and reports on electricity restoration work.

According to the data, all control rods were put in a pressure vessel immediately after the earthquake occurred at 2:46 p.m. on March 11, and the reactor came to an emergency halt. Emergency diesel generators reactivated normally.

The No. 1 reactor's emergency condenser to cool the reactor automatically activated, but about 10 minutes later pressure inside the reactor suddenly dropped. The emergency cooling system is believed to have been manually halted at around 3 p.m.

The pressure vessel's data points to the possibility that plant workers started and stopped the cooling system several times before the tsunami hit the plant at around 3:30 p.m.

A TEPCO official said the workers, following an operating manual, probably tried to prevent the inside of the reactor from getting too cold. It is not clear if the condenser was operating by 6:10 p.m. during which time there were records of manually activated operations.

The workers also started venting steam to release radioactive condensation at the No. 1 reactor from 9:15 a.m. on March 12 to protect the containment vessel from a rupture.

At the No. 2 reactor, workers tried to vent steam twice between March 13 and 15, but TEPCO could not confirm a fall in pressure inside the containment vessel. At the No. 3 reactor, workers made several attempts to vent steam after March 13.

(Mainichi Japan) May 17, 2011

Timetable to end nuclear crisis too optimistic

A timetable for bringing an end to radiation leaks from the tsunami-hit Fukushima No. 1 Nuclear Power Plant and paying compensation to those affected by the accident -- which the government's task force has just announced -- suggests that the plant operator and the government had been too optimistic about the prospects for ending the crisis.

Tokyo Electric Power Co. (TEPCO), the operator of the plant, which had released a roadmap a month ago for placing the crippled plant under control, has since unveiled a revised version. The roadmap focuses specifically on cooling down the reactors, sealing off radioactive substances and monitoring the reactors.

In contrast, the government's timetable covers a wider range of measures -- including the evacuation of residents from affected areas, health inspections, decontamination of soil tainted with radiation, securing jobs for residents of crisis-hit areas and compensation for victims.

In particular, measures to lessen health hazards that radioactive substances can cause, specific relief measures for evacuees and prospects of when they can go home are important matters of concern for many people. The government should have shown these issues much earlier. The government is urged to promptly implement various measures that meet the needs of residents affected by the crisis.

The review of the roadmap for getting the reactors under control, based on which other measures have been worked out, has raised various questions. TEPCO has not changed its original schedule for bringing the affected reactors to a stable condition, known as a "cold shutdown," and reducing the amount of water contaminated with radiation in them. The government has approved TEPCO's original schedule.

TEPCO began to release initial data on **May 16** showing what actually happened to the Fukushima No. 1 Nuclear Power Plant immediately after the Great East Japan Earthquake occurred on March 11. The data has suggested that **the meltdown occurred at its No. 1, 2 and 3 reactors and that their pressure vessels were damaged.**

Nuclear fuel is believed to have melted in the reactors, and dropped to the bottom of the pressure vessels, causing radioactive water to leak into their containment vessels. The containment vessels are also feared to be damaged and are leaking a massive amount of radioactive water. Moreover, there is a possibility that nuclear fuel that has melted has leaked into the containment vessels.

The government and TEPCO should have suspected that such trouble occurred even without the initial data. TEPCO's initial roadmap was based on its overly optimistic perception of the state of affairs at the plant, and needs to be thoroughly reviewed.

It is a matter of course that TEPCO has been forced to abandon filling the containment vessels with water to seal off the pressure vessels. However, questions remain as to how to install heat exchanges to the crippled reactors and ensure that water is cycled inside them in order to permanently place them under control. Another problem is how to promptly shield the reactors in a bid to prevent radioactive water from leaking into the soil and contaminating underground water and the sea.

The government and TEPCO need to accurately grasp the state of affairs at the reactors, work out specific countermeasures and explain them to the public. If their efforts to place the reactors under control are based on their overly optimistic prospects because they want evacuees to return home as early as possible, it will be counterproductive.

Needless to say, it is an important task to **improve the work environment for workers struggling to place the nuclear plant under control and to secure skilled workers.** TEPCO has incorporated measures to improve the working environment at the plant in its revised roadmap, while the government has shown specific measures to improve health management for the workers. The government and TEPCO should steadily implement these measures.

New York Times

With Reactor Damage Thought to Be Worse, Tokyo Utility Sticks to Plan

By [HIROKO TABUCHI](#)

TOKYO — [Japan](#) vowed Tuesday to stick to its goal of stabilizing a stricken nuclear power plant in as soon as six months, despite recently acknowledging that damage to the plant's reactors might be worse than initially estimated.

The operator of the Fukushima Daiichi nuclear power plant, Tokyo Electric Power Company, has in the past week offered a graver account of how the accident unfolded after the facility was ravaged by the tsunami that followed the March 11 earthquake. The company now acknowledges that a fuel meltdown occurred at three of the plant's six reactors in the early hours of the crisis, something experts had been suggesting for weeks.

"Even though we have confirmed that the nuclear core melted soon after the accident, our three- to six-month timeline will not change," Tokyo Electric's nuclear chief, Sakae Muto, said at a news conference on Tuesday.

Tokyo Electric said it would change some aspects of its plan to bring the reactors to what it called a "cold shutdown," where temperatures at the core fall below the boiling point.

The utility no longer plans to fill up the reactors with water to stabilize them, it said. Instead, the company will now try to keep the reactors cool by building self-circulating cooling systems at the damaged reactors.

Workers have been pumping water into the reactors since the first days of the accident, but have allowed contaminated water to seep out, causing dangerous runoff, some of which has spilled into the Pacific Ocean.

Tokyo Electric will also drape a large polystyrene cover around the severely damaged outer structure of Reactor 1 in an attempt to reduce radiation emissions, and to shield the building from summer typhoons.

To protect the plant from tsunami risks, Tokyo Electric will start placing stone-filled cages as makeshift armor units along the site's shoreline.

Stabilizing the reactors would allow workers to start dismantling and decontaminating the site, a process which experts have said will take at least a decade. About 80,000 people who lived around the plant, 140 miles north of Tokyo, have fled their homes, while thousands of farmers and fishermen risk losing their livelihoods as contamination spreads from the plant.

It is unclear whether even six to nine months will be enough to start a cleanup. Tokyo Electric in the past week has released data that show that the fuel rods at the three most damaged reactors started to melt down rapidly after the site was jolted by a quake at 2:46 p.m. on March 11, knocking out its external power supply. Less than an hour later, the plant was overrun by a 50-foot tsunami, which inundated the plant's backup diesel generators, according to the company.

The crisis worsened rapidly after that. At 7:30 p.m. on March 11, less than five hours after the quake, damage began to the nuclear fuel at Reactor 1, the company now says.

Twenty minutes later, an uncontrolled meltdown had begun, as fuel started to slump to the bottom of the reactor pressure vessel.

By 9 p.m. on the 11th, temperatures had reached 2,800 degrees Celsius, the melting point of the uranium nuclear fuel rods, leading most of the fuel to fall to the bottom of the reactor vessel. The company says meltdown also happened at Reactors No. 2 and 3.

Tokyo Electric officials had previously said that the uranium fuel rods in the reactors' cores were likely to have melted only partly.

The high temperatures also caused the fuel rods' zirconium cladding to react chemically with water, producing hydrogen gas. That hydrogen built up inside the reactor buildings, setting off explosions at two reactors and severely damaging a third.

A fourth reactor that was not operating at the time of the accident has also been wrecked. Tokyo Electric has suggested that hydrogen may have traveled there from an adjacent reactor through pipes and vents.

The International Atomic Energy Agency will send a fact-finding mission to Japan next week, the government said Tuesday.

Japan's chief cabinet secretary, Yukio Edano, said that the 20-member team will spend about a week in Japan and report its findings in June.

In Japan Reactor Failings, Danger Signs for the U.S.

By HIROKO TABUCHI, KEITH BRADSHER and MATTHEW L. WALD

*This article is by **Hiroko Tabuchi**, **Keith Bradsher** and **Matthew L. Wald**.*

TOKYO — Emergency vents that American officials have said would prevent devastating hydrogen explosions at nuclear plants in the United States were put to the test in Japan — and failed to work, according to experts and officials with the company that operates the crippled Fukushima Daiichi plant.

The failure of the vents calls into question the safety of similar nuclear power plants in the United States and Japan. After the venting failed at the Fukushima plant, the hydrogen gas fueled explosions that spewed radioactive materials into the atmosphere, reaching levels about 10 percent of estimated emissions at Chernobyl, according to Japan's nuclear regulatory agency.

Venting was critical to relieving pressure that was building up inside several reactors after the March 11 tsunami knocked out the plant's crucial cooling systems. Without flowing water to cool the reactors' cores, they had begun to dangerously overheat.

American officials had said early on that reactors in the United States would be safe from such disasters because they were equipped with new, stronger venting systems. But Tokyo Electric Power Company, which runs the plant, now says that Fukushima Daiichi had installed the same vents years ago.

Government officials have also suggested that one of the primary causes of the explosions was a several-hour delay in a decision to use the vents, as Tokyo Electric managers agonized over whether to resort to emergency measures that would allow a substantial amount of radioactive materials to escape into the air.

But the release this week of company documents and interviews with experts **provides the most comprehensive evidence yet that mechanical failures and design flaws in the venting system also contributed to delays.** The documents paint a picture of **increasing desperation** at the plant in the early hours of the disaster, as workers who had finally gotten the go-ahead to vent realized that the system would not respond to their commands.

While venting would have allowed some radioactive materials to escape, analysts say that those releases would have been far smaller than those that followed the explosions at three of the plant's reactors, which blew open containment buildings meant to serve as a first line of defense against catastrophe. The blasts may also have been responsible for breaches in containment vessels that have complicated efforts to cool the fuel rods and contain radioactive leaks from the site.

One reason the venting system at the plant, which was built by **General Electric**, did not work is that it relied on the same sources of electricity as the rest of the plant: backup generators that were in basements at the plant and vulnerable to tsunamis. But the earthquake may also have damaged the valves that are part of the venting system, preventing them from working even when operators tried to manually open them, Tokyo Electric officials said.

In either case, regulators in the United States and Japan will now need to determine if such systems at similar plants designed by G.E. need to undergo expensive and time-consuming retrofitting or redesign to allow them to function even in severe accidents.

"Japan is going to teach us lessons," said David Lochbaum at the Union of Concerned Scientists. **"If we're in a situation where we can't vent where we need to, we need to fix that."**

Officials from General Electric did not comment on Tuesday.

The seriousness of the crisis at the Fukushima plant became evident within hours of the quake and the tsunami that rushed over the plant's sea wall.

Just 12 hours after the quake, the pressure inside Reactor No. 1 had reached roughly twice the maximum pressure the unit had been designed to withstand, raising fears that the vessels that house fuel rods would rupture, setting a possible meltdown in motion. With the pressure high, pumping in additional cooling water also was not possible.

The government became rattled enough that it ordered Tokyo Electric to begin venting. But even then, Tokyo Electric's executives continued to deliberate, according to a person close to government efforts to bring the reactors under control. The exchanges became so heated, the person said, that the company's nuclear chief, Vice President Sakae Muto, and the stricken plant's director, Masao Yoshida, engaged in a "shouting match" — a rarity in reserved Japan.

Mr. Yoshida wanted to vent as soon as possible, but Mr. Muto was skeptical whether venting would work, the person said, requesting anonymity because he is still an adviser to the government and is not permitted to comment publicly. "There was **hesitation, arguments and sheer confusion over what to do,**" he said.

The executives did not give the order to begin venting until Saturday — more than 17 hours after the tsunami struck and 6 hours after the government order to vent.

As workers scrambled to comply with their new directive, they faced a cascading series of complications.

The venting system is designed to be operated from the control room, but operators' attempts to turn it on failed, most likely because the power to open critical valves was out. The valves are designed so they can also be opened manually, but by that time, workers found radiation levels near the venting system at Reactor No. 1 were already too high to approach, according to Tokyo Electric's records.

At Reactor No. 2, workers tried to manually open the safety valves, but pressure did not fall inside the reactor, making it unclear whether venting was successful, the records show. At Reactor No. 3, workers tried seven times to manually open the valve, but it kept closing, the records say.

The results of the failed venting were disastrous.

Reactor No. 1 exploded first, on Saturday, the day after the earthquake. Reactor No. 3 came next, on Monday. And No. 2 exploded early Tuesday morning.

With each explosion, radioactive materials surged into the air, forcing the evacuation of tens of thousands of earthquake survivors living near the plant, contaminating crops and sending a faint plume of radioactive isotopes as far as the United States within days. Aerial photos of the reactor buildings showed No. 1 and 3 had been blown apart and another was seriously damaged.

As the troubles mounted, Tokyo Electric and government officials conducted a series of news conferences that began to suggest the scope of the damage. The blasts, they said, probably caused breaches in containment vessels that are among the final layers of protection against meltdowns and even larger releases of radioactive materials.

Tokyo Electric in recent days has acknowledged that damage at the plant was worse than previously thought, with fuel rods most likely melting completely at Reactors 1, 2 and 3 in the early hours of the crisis, raising the danger of more catastrophic releases of radioactive materials. The company also said new evidence seemed to confirm that at Reactor No. 1, the pressure vessel, the last layer of protection, was broken and leaking radioactive water.

The improved venting system at the Fukushima plant was first mandated for use in the United States in the late 1980s as part of a “safety enhancement program” for boiling-water reactors that used the Mark I containment system, which had been designed by General Electric in the 1960s. Between 1998 and 2001, Tokyo Electric followed suit at Fukushima Daiichi, where five of six reactors use the Mark I design.

The company said that was the case this week, after a review of Japanese regulatory filings made in 2002 showed that the vents had been installed.

The fortified venting system addressed concerns that the existing systems were not strong enough to channel pent-up pressure inside the reactors in an emergency. Pressure would be expected to rise along with temperature, damaging the zirconium cladding on the fuel rods at the reactor core and allowing them to react chemically with water to produce zirconium oxide and hydrogen gas.

The new vents were designed to send steam and gas directly from the reactor’s primary containment, which houses the reactor vessel, racing past the usual filters and gas treatment systems that would normally slow releases of gas and eliminate most radioactive materials.

But the emergency vents were fitted with numerous safeguards, some of which require electricity to work, rendering them useless when all power is lost at a nuclear plant, experts say.

The most important of those safeguards are the valves, operated from a switch under lock and key in the control room, that must be opened for the vents to work. When a key is inserted into the keyboard in the nuclear reactor’s control room and turned, the valves are supposed to open, letting gases rush out of the reactor building.

Tokyo Electric has said the valves did not work at Fukushima Daiichi after the power failed.

That would suggest that operators of similar plants in the United States and Japan could protect reactors by moving generators to higher floors if the equipment is currently in places that could be affected by tsunamis or flooding from rivers.

But a redesign of the venting system itself might also be necessary.

The design is the result of conflicting schools of thought among United States nuclear officials, said Michael Friedlander, a former senior operator at several American nuclear power plants.

Mr. Friedlander said, referring to the Nuclear Regulatory Commission: “You have the N.R.C. containment isolation guys who want containment closed, always, under every conceivable accident scenario, and then you’ve got the reactor safety guys who need containment to be vented under severe accident scenarios. It is a very controversial system.”

Hiroko Tabuchi reported from Tokyo, Keith Bradsher from Hong Kong, and Matthew L. Wald from Washington.

Venting failed twice at Fukushima plant, possibly damaging reactor

TOKYO, May 18, Kyodo

The operator of the crippled Fukushima Daiichi nuclear power plant failed twice to vent steam out of the containment vessel of the No. 2 reactor, most likely resulting in damage done to part of it, a plant operator source said Wednesday.

The failure in the immediate aftermath of the March 11 earthquake and tsunami and subsequent trouble at the plant, such as the release of massive amounts of radioactive material into the air and the discharge of contaminated water, call into question Tokyo Electric Power Co.'s crisis management, observers say.

The world's worst nuclear crisis since the 1986 Chernobyl disaster has yet to be contained, with the government and the utility struggling to restart key cooling functions at most of the six reactors there.

Radioactive water released at U.S. request: Cabinet adviser

SEOUL (Kyodo) -- Japanese playwright Oriza Hirata, who serves as a special adviser to the Cabinet, **claimed in a recent lecture given here that the dumping of low-level radioactive water into the Pacific Ocean was done at the "strong request" from the United States**, a person who attended the lecture said Wednesday.

The release of the water from the Fukushima Daiichi nuclear power plant last month generated anxiety about the possible spread of radioactive contamination from the seaside power station.

The Japanese government had apparently given its permission for the release of the water after receiving a report from plant operator Tokyo Electric Power Co.

Hirata's remarks, made Tuesday, that the release was not carried out based on Tokyo's independent judgment but rather on a request from Washington is likely to ignite a discussion.

South Korea and other neighboring countries have voiced concerns over a lack of prior notification of the tainted water discharge.

Hirata's lecture in Seoul was titled "Earthquakes and the Revitalization of Japan," and in response to a question at the venue, he called Japan's failure to give advance notification an error of communication.

While acknowledging that the release of the water caused concern in South Korea, **he said the water that was discharged had an extremely low radioactivity and the quantity was small. [ah bon ?]**

Speaking at a news conference in Tokyo on Wednesday, Chief Cabinet Secretary Yukio Edano said that he was "not aware" of the release of the water being carried out at the request of the United States.

"I would like to confirm with him afterward based on what recognition he was speaking," Edano said, indicating that he intends to question Hirata on his claim of U.S. intervention.

(Mainichi Japan) May 18, 2011

Workers enter another reactor building at crippled Fukushima plant

TOKYO (Kyodo) -- Workers trying to restore the Fukushima Daiichi nuclear power plant on Wednesday entered the building housing the troubled No. 2 reactor for the first time since an explosion occurred inside the building in the early days of the nuclear crisis.

Plant operator Tokyo Electric Power Co. has already sent people inside the No. 1 reactor building to make preparations to create a system to stably cool the nuclear fuel, and similar work is expected to take place inside the No. 2 reactor, such as checking the equipment and adjusting the reactor's gauges that may have some malfunctions.

The utility known as TEPCO is struggling to contain the nuclear crisis, triggered in the wake of the March 11 earthquake and tsunami, in line with a road map that aims to bring the crippled Nos. 1 to 3 reactors to a stable cooling condition by mid-July and to a condition called "cold shutdown" by January at the latest.

In an updated version of its road map unveiled Tuesday, TEPCO did not change the broad restoration time frame, but said **it plans to create a system to cool the three reactors by recycling massive amounts of radioactive water now filling up the reactor buildings and the adjacent reactor turbine buildings.**

The water would be recycled by using a decontamination facility, scheduled to be set up in mid-June. TEPCO said it now estimates that **roughly 84,700 tons of relatively highly radioactive water are in the Nos. 1 to 4 reactor buildings, reactor turbine buildings and nearby underground trenches.**

The pools of water are believed to be a side effect of an emergency measure after the disaster to keep injecting water into the reactors and spent fuel pools, which lost their key cooling functions in the quake and tsunami, to prevent the fuel inside from overheating.

The latest findings have suggested that the No. 1 reactor core suffered a meltdown shortly after the plant was rattled by the earthquake, and **government officials have emphasized the need to act on the assumption that the Nos. 2 and 3 reactor cores may also be in a similar situation.**

On Wednesday morning, four TEPCO workers entered the No. 2 reactor building **for about 15 minutes. They were exposed to radiation of between 3.33 and 4.27 millisieverts,** TEPCO said.

The environment inside the No. 2 reactor building is tough for workers not only because of the high radiation level but also the high humidity that can be attributed to steam coming out from the pool that stores the spent nuclear fuel, it said.

TEPCO spokesman Junichi Matsumoto told a press conference in the afternoon that the company plans to install a device to efficiently cool the water inside the spent fuel pool and start the system's test-run May 31.

The system is also expected to help lower the humidity inside the building, which would mean an improvement in the working conditions there, according to the government's Nuclear and Industrial Safety Agency.

TEPCO will speak on Thursday about the outcome of the radiation level and other data obtained from the entry into the No. 2 reactor building, Matsumoto said.

Meanwhile, Economy, Trade and Industry Minister Banri Kaieda told a separate press conference that he thinks the direct cause of the crisis was the giant tsunami that led the plant to lose all its power sources, rather than the quake, denying speculation that key reactor equipment may have suffered damage before the power loss occurred. [????????]

Such speculation has emerged after it was found that the radiation level inside the No. 1 reactor building was already high on the night of March 11.

(Mainichi Japan) May 19, 2011

5 tons of seawater may have entered Hamaoka nuclear reactor

SHIZUOKA, Japan, May 19, Kyodo

Around five tons of seawater may have entered one of the reactors at the Hamaoka nuclear power plant in Shizuoka Prefecture along with about 400 tons of seawater found in its steam condenser when work was under way Sunday to put the reactor into a state of "cold shutdown," Chubu Electric Power Co., the plant operator, said Thursday.

The reactor will not be decommissioned because the utility will dilute and desalinate the seawater in an effort to prevent any corrosion inside the reactor, the company said.

Seawater might have entered from damaged piping inside the condenser, which cools steam from the turbine and turns it into water.

Cabinet adviser retracts remark about release of contaminated water

TOKYO (Kyodo) -- Cabinet adviser Oriza Hirata has retracted a recent remark that low-level radioactive water was dumped from the troubled Fukushima No. 1 Nuclear Power Plant into the Pacific in April at the "strong request" of the United States, his office said Thursday.

In a statement issued by his office, Hirata, a playwright who has served in the government post since October 2009, said he had confused the dumping of the radioactive water with another matter when he made the controversial comment during a lecture in Seoul on Tuesday, offering an apology.

Hirata, 48, said in the statement that he has not visited the prime minister's office since the March 11 earthquake and tsunami, and that he is not in a position to know about developments in the nuclear crisis.

Chief Cabinet Secretary Yukio Edano, the top government spokesman, told a morning news conference that he had received an apology from Hirata for making what the adviser called an **"improper remark."**

The release of low-level radioactive water into the sea, carried out with the government's permission, generated anxiety among neighboring countries such as South Korea.

Gov't to scrap upper limit of radiation exposure for workers at Fukushima plant

The government has decided to abolish the upper cap of radiation exposure for workers at the disaster-crippled Fukushima No. 1 Nuclear Power Plant, drawing concern from experts, it has been learned.

The Ministry of Health, Labor and Welfare decided to lift the yearly 50-millisievert maximum permissible amount of radiation exposure for workers at the troubled Fukushima plant in the face of the prolonged restoration work at the facility.

The ministry has notified the Japanese Trade Union Confederation (Rengo) -- Japan's largest labor organization -- of the decision in writing. The ministry will uphold the combined 100-millisievert maximum allowable exposure for workers over a five-year period, inclusive of doses they are exposed to during regular inspections of other nuclear power plants.

The move came after **it became likely that workers at the Fukushima plant would not be able to be engaged in regular inspections at other nuclear power generation facilities after their stint at**

Fukushima. However, experts are voicing concerns over the change of policy, saying it could adversely affect the workers' health.

The ministry had earlier upgraded the yearly limit of 100-millisievert accumulated exposure in emergencies to 250 millisieverts only for workers at the Fukushima plant, while leaving a decision whether to allow the doses to be combined with those they are exposed to during regular inspections at other nuclear plants unclear.

In a notice issued on April 28, the ministry clearly stated that workers should be exposed to no more than 100 millisieverts of radiation over a five-year period and that the yearly limit of 50 millisieverts should be upheld for workers at other facilities than the Fukushima plant.

According to sources close to the case, the ministry's notice was distributed at an ad-hoc meeting at Rengo's Tokyo headquarters on May 11 under the name of a division head of the ministry's Industrial Safety and Health Department. The notice stated that **workers at the Fukushima plant will not be given administrative guidance even if they are exposed to more than 50 millisieverts of radiation a year** but that they will be instructed to be exposed to no more than 100 millisieverts over a five-year period.

"We wanted to prevent our decision from being misunderstood by workers," said an official with the ministry's Industrial Health Division.

Masanobu Nishino, secretary-general of the Kansai Occupational Safety & Health Center and an expert in occupational exposure to radiation, criticized the ministry's move.

"Considering the fact that workers are exposed to only around an average 1 millisievert of radiation a year through regular inspections at nuclear power plants, even the limit of 50 millisieverts is too much and this raises concerns over workers' health. It should be the role of the health ministry to instruct workers to be exposed to no more than 50 millisieverts," Nishino said.

Cooling system pumps stop at Fukushima plant's No. 5 unit

TOKYO (Kyodo) -- Tokyo Electric Power Co. said Sunday the pumps to cool the nuclear reactor and fuel pool stopped at its crippled Fukushima No. 1 power plant's No. 5 unit.

As the temperature of the reactor rose, the operator switched to backup pumps to restore the cooling system, while investigating the cause of the trouble.

The backup pumps are a makeshift solution designed to tap seawater for cooling purposes.

When a worker at the plant became aware of the problem at 9 p.m. Saturday, the temperature of the reactor stood at 68 C and that of the fuel pool at 41 C. The figures had risen to 94 C and 46 C, respectively, as of noon Sunday, it said.

Tokyo Electric did not reveal the trouble until Sunday morning, and an official said, "We reported it to the central government and the prefectural government of Fukushima on Saturday evening, but we feel sorry that we did not announce it" immediately.

In Japan, a Culture That Promotes Nuclear Dependency

By [MARTIN FACKLER](#) and [NORIMITSU ONISHI](#)

KASHIMA, Japan — When the Shimane nuclear plant was first proposed here more than 40 years ago, this rural port town put up such fierce resistance that the plant's would-be operator, Chugoku Electric, almost scrapped the project. Angry fishermen vowed to defend areas where they had fished and harvested seaweed for generations.

Two decades later, when Chugoku Electric was considering whether to expand the plant with a third reactor, Kashima once again swung into action: this time, to rally in favor. Prodded by the local fishing cooperative, the town assembly voted 15 to 2 to make a public appeal for construction of the \$4 billion reactor.

Kashima's reversal is a common story in [Japan](#), and one that helps explain what is, so far, this nation's unwavering pursuit of nuclear power: a lack of widespread grass-roots opposition in the communities around its 54 nuclear reactors. This has held true even after the March 11 earthquake and tsunami generated a nuclear crisis at the Fukushima Daiichi station that has raised serious questions about whether this quake-prone nation has adequately ensured the safety of its plants. So far, it has spurred only muted public questioning in towns like this.

Prime Minister Naoto Kan has, at least temporarily, shelved plans to expand Japan's use of nuclear power — plans promoted by the country's powerful nuclear establishment. Communities appear willing to fight fiercely for nuclear power, despite concerns about safety that many residents refrain from voicing publicly.

To understand Kashima's about-face, one need look no further than the Fukada Sports Park, which serves the 7,500 mostly older residents here with a baseball diamond, lighted tennis courts, a soccer field and a \$35 million gymnasium with indoor pool and Olympic-size volleyball arena. **The gym is just one of several big public works projects paid for with the hundreds of millions of dollars this community is receiving for accepting the No. 3 reactor, which is still under construction.**

As Kashima's story suggests, Tokyo has been able to essentially buy the support, or at least the silent acquiescence, of communities by showering them with generous subsidies, payouts and jobs. In 2009 alone, Tokyo gave \$1.15 billion for public works projects to communities that have electric plants, according to the Ministry of Economy, Trade and Industry. Experts say the majority of that money goes to communities near nuclear plants.

And that is just the tip of the iceberg, experts say, as the communities also receive a host of subsidies, property and income tax revenues, compensation to individuals and even “anonymous” donations to local treasuries that are widely believed to come from plant operators.

Unquestionably, the aid has enriched rural communities that were rapidly losing jobs and people to the cities. With no substantial reserves of oil or coal, Japan relies on nuclear power for the energy needed to drive its economic machine. But critics contend that the largess has also made communities dependent on central government spending — and thus unwilling to rock the boat by pushing for robust safety measures.

In a process that critics have likened to drug addiction, the flow of easy money and higher-paying jobs quickly replaces the communities' original economic basis, usually farming or fishing.

Nor did planners offer alternatives to public works projects like nuclear plants. Keeping the spending spigots open became the only way to maintain newly elevated living standards.

Experts and some residents say this dependency helps explain why, despite the legacy of Hiroshima and Nagasaki, and the accidents at the Three Mile Island and Chernobyl nuclear plants, Japan never faced the levels of popular opposition to nuclear power seen in the United States and Europe — and is less likely than the United States to stop building new plants. Towns become enmeshed in the same circle — which includes politicians, bureaucrats, judges and nuclear industry executives — that has relentlessly promoted the expansion of nuclear power over safety concerns.

“This structure of dependency makes it impossible for communities to speak out against the plants or nuclear power,” said Shuji Shimizu, a professor of public finance at Fukushima University.

Code of Silence

Indeed, a code of silence seems to prevail even now in towns like Kashima, which merged with the neighboring city of Matsue a half decade ago.

Tsuneyoshi Adachi, a 63-year-old fisherman, joined the huge protests in the 1970s and 1980s against the plant's No. 2 reactor. He said many fishermen were angry then because chlorine from the pumps of the plant's No. 1 reactor, which began operating in 1974, was killing seaweed and fish in local fishing grounds.

However, Mr. Adachi said, once compensation payments from the No. 2 reactor began to flow in, neighbors began to give him cold looks and then ignore him. By the time the No. 3 reactor was proposed in the early 1990s, no one, including Mr. Adachi, was willing to speak out against the plant. He said that there was the same peer pressure even after the accident at Fukushima, which scared many here because they live within a few miles of the Shimane plant.

“Sure, we are all worried in our hearts about whether the same disaster could happen at the Shimane nuclear plant,” Mr. Adachi said. However, “the town knows it can no longer survive economically without the nuclear plant.”

While few will say so in public, many residents also quietly express concern about how their town gave up its once-busy fishing industry. They also say that flashy projects like the sports park have brought little lasting economic benefit. The No. 3 reactor alone brought the town some \$90 million in public works money, and the promise of another \$690 million in property tax revenues spread over more than 15 years once the reactor becomes operational next year.

In the 1990s, property taxes from the No. 2 reactor supplied as much as three-quarters of town tax revenues. The fact that the revenues were going to decline eventually was one factor that drove the town to seek the No. 3 reactor, said the mayor at the time, Zentaro Aoyama.

Mr. Aoyama admitted that the Fukushima accident had frightened many people here. Even so, he said, the community had no regrets about accepting the Shimane plant, which he said had raised living standards and prevented the depopulation that has hollowed out much of rural Japan.

“What would have happened here without the plant?” said Mr. Aoyama, 73, who said the town used its very first compensation payment from the No. 1 reactor back in the late 1960s to install indoor plumbing.

While the plants provide power mostly to distant urban areas, they were built in isolated, impoverished rural areas.

Kazuyoshi Nakamura, 84, recalls how difficult life was as a child in Katakū, a tiny fishing hamlet within Kashima that faces the rough Sea of Japan. His father used a tiny wooden skiff to catch squid and bream, which his mother carried on her back to market, walking narrow mountain paths in straw sandals.

Still, at first local fishermen adamantly refused to give up rights to the seaweed and fishing grounds near the plant, said Mr. Nakamura, who was a leader of Katakū’s fishing cooperative at the time. They eventually accepted compensation payments that have totaled up to \$600,000 for each fisherman.

“In the end, we gave in for money,” Mr. Nakamura said.

Today, the dirt-floor huts of Mr. Nakamura’s childhood have been replaced by oversize homes with driveways, and a tunnel has made central Kashima a five-minute drive away. But the new wealth has changed this hamlet of almost 300 in unforeseen ways. Only about 30 aging residents still make a living from fishing. Many of the rest now commute to the plant, where they work as security guards or cleaners.

“There was no need to work anymore because the money just flowed so easily,” said a former town assemblyman who twice ran unsuccessfully for mayor on an antinuclear platform.

A Flow of Cash

Much of this flow of cash was the product of the Three Power Source Development Laws, a sophisticated system of government subsidies created in 1974 by Kakuei Tanaka, the powerful prime minister who shaped Japan's nuclear power landscape and used big public works projects to build postwar Japan's most formidable political machine.

The law required all Japanese power consumers to pay, as part of their utility bills, a tax that was funneled to communities with nuclear plants. Officials at the Ministry of Economy, Trade and Industry, which regulates the nuclear industry, and oversees the subsidies, refused to specify how much communities have come to rely on those subsidies.

"This is money to promote the locality's acceptance of a nuclear plant," said Tatsumi Nakano of the ministry's Agency for Natural Resources and Energy. A spokesman for Tohoku Electric Power Company, which operates a plant in Higashidori, said that the company is not involved in the subsidies, and that since Fukushima, it has focused on reassuring the public of the safety of nuclear plants.

Political experts say the subsidies encourage not only acceptance of a plant but also, over time, its expansion. That is because subsidies are designed to peak soon after a plant or reactor becomes operational, and then decline.

"In many cases, what you'll see is that a town that was depopulating and had very little tax base gets a tremendous surge of money," said [Daniel P. Aldrich](#), a political scientist at Purdue University who has studied the laws.

As the subsidies continue to decline over the lifetime of a reactor, communities come under pressure to accept the construction of new ones, Mr. Aldrich said. "The local community gets used to the spending they got for the first reactor — and the second, third, fourth, and fifth reactors help them keep up," he added.

Critics point to the case of Futaba, the town that includes Fukushima Daiichi's No. 5 and No. 6 reactors, which began operating in 1978 and 1979, respectively.

According to Professor Shimizu of Fukushima University, Fukushima Daiichi and the nearby Fukushima Daini plants directly or indirectly employed some 11,000 people in communities that include Futaba — or about one person in every two households. Since 1974, communities in Fukushima Prefecture have received about \$3.3 billion in subsidies for its electrical plants, most of it for the two nuclear power facilities, Mr. Shimizu said.

Despite these huge subsidies, most given in the 1970s, Futaba recently began to experience budget problems. As they did in Kashima, the subsidies dwindled along with other revenues related to the nuclear plant, including property taxes. By 2007, Futaba was one of the most fiscally troubled towns in Japan and nearly went bankrupt. Town officials blamed the upkeep costs of the public facilities built in the early days of flush subsidies and poor management stemming from the belief that the subsidies would remain generous.

Eisaku Sato, who served as the governor of Fukushima Prefecture from 1988 to 2006 and became a critic of the nuclear industry, said that 30 years after its first reactor started operating, the town of Futaba could no longer pay its mayor's salary.

“With a nuclear reactor, in one generation, or about 30 years, it’s possible that you’ll become a community that won’t be able to survive,” Mr. Sato said.

Futaba’s solution to its fiscal crisis was to ask the government and Tokyo Electric, Fukushima Daiichi’s operator, to build two new reactors, which would have eventually increased the number of reactors at Fukushima Daiichi to eight. The request immediately earned Futaba new subsidies.

“Putting aside whether ‘drugs’ is the right expression,” Mr. Sato said, “if you take them one time, you’ll definitely want to take them again.”

Eiji Nakamura, the failed candidate for mayor of Kashima, said the town came to rely on the constant flow of subsidies for political as well as economic reasons. He said the prefectural and town leaders used the jobs and money from public works to secure the support of key voting blocs like the construction industry and the fishing cooperative, to which about a third of the town’s working population belongs.

“They call it a nuclear power plant, but **it should actually be called a political power plant**,” Mr. Nakamura joked.

The Most to Lose

This dependence explains why Prime Minister Kan’s talk of slowing Japan’s push for nuclear power worries few places as much as the Shimokita Peninsula, an isolated region in northern Honshu.

The peninsula’s first reactor went online in 2005, two are under construction, and two more are still being planned. Japan is also building massive nuclear waste disposal and reprocessing facilities there. As newcomers to nuclear power, Shimokita’s host communities now have the most to lose.

Consider Higashidori, a town with one working reactor and three more scheduled to start operating over the next decade. With the subsidies and other revenues from four planned reactors, town officials began building an entirely new town center two decades ago.

Serving a rapidly declining population of 7,300, the town center is now dominated by three gigantic, and barely used, buildings in the shape of a triangle, a circle and a square, which, according to the Tokyo-based designer, symbolize man, woman and child. Nearby, a sprawling campus with two running tracks, two large gymnasiums, eight tennis courts and an indoor baseball field serves fewer than 600 elementary and junior high school children. In 2010, nearly 46 percent of the town’s \$94 million budget came from nuclear-related subsidies and property taxes.

Shigenori Sasatake, a town official overseeing nuclear power, said Higashidori hoped that the Japanese government and plant operators would not waver from their commitment to build three more reactors there, despite the risks exposed at Fukushima.

“Because there are risks, there is no way reactors would be built in Tokyo, but only here in this kind of rural area,” Mr. Sasatake said, adding that town officials harbored no regrets about having undertaken such grandiose building projects.

But Higashidori's building spree raised eyebrows in Oma, another peninsula town, with 6,300 residents, where construction on its first reactor, scheduled to start operating in 2014, was halted after the Fukushima disaster.

Tsuneyoshi Asami, a former mayor who played a critical role in bringing the plant to Oma, said that the town did not want to be stuck with fancy but useless buildings that would create fiscal problems in the future. So far, Oma has resisted building a new town hall, using nuclear subsidies instead to construct educational and fisheries facilities, as well as a home for the elderly.

"Regular people and town council members kept saying that no other community where a plant was located has stopped at only one reactor — that there was always a second or third one — so we should be spending more," Mr. Asami said. "But I said no."

Still, even in Oma, there were worries that the Fukushima disaster would indefinitely delay the construction of its plant. It is just the latest example of how the system of subsidies and dependency Japan created to expand nuclear power makes it difficult for the country to reverse course.

"We absolutely need it," Yoshifumi Matsuyama, the chairman of Oma's Chamber of Commerce, said of the plant. "Nothing other than a nuclear plant will bring money here. That's for sure. What else can an isolated town like this do except host a nuclear plant?"

TEPCO begins streaming video of Fukushima nuclear plant on homepage

A still taken from the Fuku-Ichi Live Camera stream at about 7 p.m. on May 30. (Image courtesy of TEPCO)

Anyone seeking a peek inside the crippled Fukushima No. 1 Nuclear Power Plant can now check up on the goings on there anytime of the day with a new 24-hour camera feed, available through plant operator Tokyo Electric Power Co. (TEPCO)'s website.

TEPCO put the feed from the "Fuku-Ichi Live Camera" up on its homepage at 10 a.m. on May 31. The camera is mounted close to the plant's main administrative building, about 250 meters from the No. 1 reactor, and provides views of reactors No. 1 to 4. The video relay will lag about 30 seconds. TEPCO

also says it hopes to provide annotations to explain any fires or other serious events captured by the camera.

The video feed can be found at: <http://www.tepco.co.jp/nu/f1-np/camera/index-j.html>.

Oil briefly leaked into sea close to crippled Fukushima nuke plant

TOKYO, May 31, Kyodo

Oil has temporarily leaked into the sea near the crisis-hit Fukushima Daiichi nuclear power plant from an oil pipe that may have been damaged in the March 11 earthquake and tsunami, the plant operator said Tuesday, adding it set up oil fences to prevent the liquid from spreading into the Pacific Ocean.

In another incident, the sound of an explosion was heard in the afternoon near the No. 4 reactor building because remote-controlled heavy machinery damaged an oxygen cylinder when removing rubble, Tokyo Electric Power Co. said. No one was injured and the radiation level at the area remained stable, it added.

As for the oil problem, Goshi Hosono, a senior government official tasked with handling the nuclear crisis, said in a press conference jointly held with Tokyo Electric in the afternoon that the amount of leakage was found to be "extremely small."

JUIN 2011

TEPCO starts system to cool spent fuel pool at Fukushima plant

TOKYO (Kyodo) -- The operator of the crippled Fukushima No. 1 Nuclear Power Plant said that it has started to fully operate a water circulation system to **stably cool one of the pools storing spent nuclear fuel at the plant**, marking progress in its efforts to bring the nuclear crisis under control.

Tokyo Electric Power Co. said, meanwhile, it had discovered that oil temporarily leaked into the sea near the plant located on the Pacific coast, while an oxygen cylinder ruptured during work to remove rubble earlier in the day.

The utility known as TEPCO is trying to contain the world's worst nuclear crisis since the 1986 Chernobyl disaster, in line with a road map that aims to stabilize sometime between October and January the plant's reactors and spent fuel pools, which lost their key cooling functions in the wake of the massive March 11 earthquake and tsunami.

The new water circulation cooling system was established for the spent fuel pool in the No. 2 reactor building. The system is also expected to **help lower the extremely high humidity detected inside the building by reducing steam coming out from the hot water in the pool** and to improve the working environment inside the building.

TEPCO spokesman Junichi Matsumoto said that the temperature of **the pool's water is expected to fall to around 40 C from about 70-80 C by operating the system for about a month.**

Similar systems are to be created for the spent fuel pools of the Nos. 1 and 3 units in June, as well as for the No. 4 unit in around July.

But on the same day, TEPCO found that oil had temporarily leaked into the sea near the plant from an oil pipe that may have been damaged in the March disaster. It said the leak has stopped and hastily set up oil fences to prevent the liquid from spreading into the Pacific Ocean.

Goshi Hosono, a senior government official tasked with handling the nuclear crisis, said in a press conference jointly held with TEPCO's Matsumoto and others in the afternoon that the amount of oil involved was "extremely small."

TEPCO workers detected the **oil slick, which extended for 200 to 300 meters inside breakwaters** at one point, at 8 a.m. when patrolling the plant.

Tokyo Electric suspects the oil leaked from a pipe believed to be connected to two heavy oil tanks located near the water intake for the Nos. 5 and 6 reactors. Recent typhoon-affected rainy weather may also have led to the leak, it said.

When the March 11 disaster struck the plant, a tanker was supplying oil to the tanks, each with a capacity of 960 kiloliters. One of them was moved from its original location because of the tsunami.

Aside from the oil spill, the sea close to the plant was earlier contaminated with highly radioactive water that leaked from the plant.

To reduce contamination of seawater enclosed inside the harbor, TEPCO said it will start test-operating from Wednesday a system to **pump out the water and extract radioactive materials from it by using a mineral called zeolite.**

In another incident, an explosion was heard at 2:30 p.m. near the No. 4 reactor building after remote-controlled heavy machinery damaged an oxygen cylinder while rubble was being removed. No one was injured and the radiation level in the area remained stable, TEPCO added.

Meanwhile, it was also revealed Tuesday that the head of a government task force on the Fukushima disaster has been absent since May 19 because of illness.

The task force head, senior vice industry minister Motohisa Ikeda, has been hospitalized, Economy, Trade and Industry Minister Banri Kaieda told a parliamentary committee.

A senior bureaucrat of the Nuclear and Industrial Safety Agency has been serving as acting chief, but the government had not announced the fact.

Audits de sûreté nucléaire : l'Union européenne se range à la proposition des régulateurs

À l'issue de deux semaines de négociation, le commissaire européen à l'Energie a finalement validé les stress-tests proposés le 13 mai par les régulateurs. La sûreté et la sécurité feront l'objet de deux audits distincts.

| 26 Mai 2011 | Actu-Environnement.com

La Commission européenne et les régulateurs européens ont annoncé mercredi 25 mai 2011 avoir trouvé un compromis sur le contenu et la forme des tests de résistance que passeront les centrales nucléaires de l'Union. Les audits de sûreté pourront débuter dès le 1er juin, se félicite la Commission, pour un rendu à l'occasion du sommet européen du 9 décembre.

Concrètement, l'exécutif européen a validé l'approche proposée par le Groupe des régulateurs européens dans le domaine de la sûreté nucléaire (ENSREG). Selon des diplomates interrogés par Reuters, l'accord aurait été scellé mardi soir après que l'Autriche ait finalement approuvé les propositions des régulateurs. Les deux dernières semaines de négociation n'ont finalement rien apporté puisque [le document de l'ENSREG](#) validé par la Commission, date du 13 mai 2011.

Les audits nationaux évalués par un groupe de sept experts

Les questions de sûreté des installations et le thème de la sécurité face à des actes terroristes ou la chute d'un avion feront donc l'objet de [deux évaluations distinctes](#).

Les [propositions](#) de l'Association des responsables des autorités de sûreté nucléaire des pays d'Europe de l'Ouest (Wenra) serviront de base à l'audit de sûreté.

Cette évaluation se déroulera en trois étapes. Tout d'abord, les opérateurs des centrales nucléaires répondront à un questionnaire reprenant les éléments des tests de résistance. Ensuite les régulateurs nationaux vérifieront la crédibilité des réponses et rédigeront un rapport de synthèse. Enfin, une équipe internationale, composé d'un représentant de la Commission et de six représentants choisis parmi les 27 régulateurs des Etats membres, passera en revue les rapports. Le groupe d'experts, dont la composition exacte sera définie ultérieurement, pourra visiter certains sites pour valider les rapports des régulateurs et ses conclusions seront rendues publiques.

Vers la création d'un groupe de travail sur la sécurité

Quant à la sécurité, elle fera l'objet d'un groupe de travail chargé de définir la nature des tests. *"Les menaces liées à la sécurité ne font pas partie du mandat de l'ENSREG et la prévention et les réponses à apporter aux accidents causés par des actes malveillants ou terroristes (y compris les chutes d'avion) concernent d'autres autorités"* explique le document validé par la Commission, précisant qu'*"afin de prendre en compte ces questions, il est proposé que le Conseil établisse un groupe de travail spécifique composé de représentants des Etats membres et de la Commission, selon leur compétence respective."*

Jusqu'à maintenant, Günther Oettinger, le commissaire européen à l'énergie, refusait de distinguer l'évaluation de la sûreté et de la sécurité des installations nucléaires. Cependant, au cours des négociations avec les régulateurs, il s'était rangé à cette option, mais en contrepartie il avait émis le souhait d'avoir la mainmise sur la composition du groupe de travail sur la sécurité.

À l'issue de la négociation, le Commissaire semble finalement avoir renoncé à cette revendication. Il évoque maintenant *"le besoin de confidentialité"* afin de justifier le traitement distinct des questions de sécurité.

Les Verts critiquent le manque de fermeté de Günther Oettinger

La conclusion semble bien éloignée de [la fermeté affichée par le commissaire devant les parlementaires européens](#) puisque Günther Oettinger est maintenant *"très satisfait"* du compromis même s'il reconnaît implicitement certaines limites aux tests. En particulier, [le caractère facultatif des audits](#) et l'impossibilité pour la Commission d'imposer la fermeture des réacteurs les moins fiables posent problème. *"Je sais qu'il y a des attentes en ce sens au Parlement européen, en Allemagne et en Autriche, mais ce ne sera pas le cas, car ce n'est pas mon mandat"* a-t-il expliqué en rappelant les prérogatives des Etats membres en matière de politique énergétique.

Pour le groupe Verts au Parlement européen, *"ces tests sont loin d'avoir la rigueur nécessaire pour évaluer correctement la sûreté [des] réacteurs et réduire au maximum le risque d'accident."*

Les eurodéputés, et notamment Michèle Rivasi et Yannick Jadot, estiment que *"Günther Oettinger a perdu la lutte face aux autorités britanniques et françaises."* Selon les écologistes, il *"n'a pas réussi à imposer des stress tests totalement transparents et indépendants, qui prennent en compte tous les"*

critères nécessaires" et cela bien qu'il ait "longtemps campé sur ses positions et affirmé qu'il prendrait en compte les attentats terroristes dans le cahier des charges."

TEPCO to resume transferring toxic water at Fukushima plant

TOKYO, June 2, Kyodo

The operator of the crippled Fukushima Daiichi nuclear power plant plans to resume transferring radioactive-contaminated water within the No. 3 reactor's turbine building by securing additional room to pool it, company officials said Thursday.

Tokyo Electric Power Co. was set to resume the operation at a time it is working **to prevent the tainted water from spilling out of pits and other facilities at the plant** before activating new equipment that can recycle the problem water to cool down reactors about two weeks later.

The utility sees **the amount of tainted water increasing in turbine buildings and nearby pits at the station as a recent typhoon brought substantial rainfall to the complex**, 220 kilometers northeast of Tokyo. **The rainy season zone is also approaching** Fukushima Prefecture and other areas in the northeastern Tohoku region.

Japan mulls evacuating radiation 'hot spots'

TOKYO (Kyodo) -- The government is considering expanding the scope of its evacuation order **to include people from certain spots that are emitting high levels of radiation as a result of the nuclear accident at the Fukushima No. 1 power plant in March**, government officials said.

The government will be discussing with municipalities these so-called "hot spots" suffering from radiation exposure that would exceed the **yardstick of 20 millisieverts during the course of a year**.

A hot spot refers to an area that has a high level of radiation following rain or as a result of landscape or wind conditions that affect the direction in which radioactive materials travel after being released into the air.

Normally, radiation spreads concentrically but under such conditions, radioactive materials spread randomly to various spots.

Top government spokesman Yukio Edano said at a news conference there are certain spots, other than the government-designated evacuation areas, where radiation levels are high depending on atmospheric and other conditions, and the government will boost monitoring at these locations.

"Based on the outcome of (radiation) monitoring, we will consider taking appropriate action," the chief Cabinet secretary told a news conference, hinting at the possible evacuation of these areas.

Separately, Deputy Chief Cabinet Secretary Tetsuro Fukuyama told an opposition lawmaker that **some parts of Minamisoma city in Fukushima have registered high levels of radiation**, and the government will consult with the mayor and other officials on whether or not to evacuate the residents there.

Following the devastating March 11 earthquake and tsunami that triggered a nuclear emergency, the government ordered the evacuation of people living within 30 kilometers of the Fukushima Daiichi plant, which lost its key cooling functions and continues to spew radiation.

The government has since prohibited people from entering areas within a 20-kilometer radius of the crippled Fukushima plant and added some towns outside the limit to the list of areas covered by its evacuation directive due to concerns over high levels of radiation exposure.

Japan starts probe into Fukushima nuke crisis under expert panel

TOKYO (Kyodo) -- Japan has started looking into the causes of the nuclear crisis at the Fukushima Daiichi power plant three months after it was triggered by the March 11 massive earthquake and tsunami, with an **independent panel of experts** holding their first gathering Tuesday in Tokyo.

The move marks the beginning of a comprehensive investigation of the world's worst nuclear crisis in 25 years since Chernobyl. The steps taken by the plant operator to deal with the disaster, often criticized as belated, as well as the government's response will be under scrutiny, but the panel does not intend to pursue the responsibilities of the people involved.

The panel, led by Yotaro Hatamura, a researcher on human error.

plans to compile a midterm report of their findings by the end of this year and a final report sometime after the crisis is settled.

At the outset of the meeting, Prime Minister Naoto Kan called on the members to make "firm judgments as a panel independent from the government," and said he is willing to be questioned as part of the panel's investigation process.

"I would like to ask for a report that can live up to scrutiny from around the world," Kan said.

Hatamura, a professor emeritus at the University of Tokyo, said, "**I think it is a mistake to consider it safe.**" He also suggested the panel will inspect the crippled Fukushima plant as early as this month.

The panel is entitled to question people concerned, including officials of the plant operator Tokyo Electric Power Co., related Cabinet members and government bureaucrats, but Hatamura was negative about the idea of making people speak about the facts in exchange for immunity.

"If we think about granting an exemption under the Japanese law, it may take about two or three years to decide on it...and people would forget about the issues which we want to investigate by that time," he told a press conference after the meeting. "So we will do what is best under this current framework."

The country's nuclear safety regulatory system is also expected to be examined amid criticism over whether it is appropriate to have the nuclear regulatory agency under the wing of the industry ministry that promotes nuclear power.

The investigation process, however, is apparently difficult because relevant people are still working to bring the troubled plant under control.

The panel consists of a total of 10 members, including nonfiction writer Kunio Yanagida, Michio Furukawa, mayor of the town of Kawamata in Fukushima Prefecture, and Yukio Takasu, Japan's former ambassador to the United Nations.

Hit by the magnitude 9.0 earthquake and tsunami waves more than 14 meters high, the six-reactor nuclear complex lost nearly all of its power sources, leading the cooling functions of the reactors and spent nuclear fuel pools at the Nos. 1 to 4 units to fail.

The Nos. 1 to 3 reactors' cores are assumed to have suffered meltdowns, although the melted fuel is now believed to be kept cool at the bottom of each reactor pressure vessel because water is being injected into the vessel as an emergency measure.

The remaining Nos. 4 to 6 reactors were under maintenance at the time of the earthquake and the No. 4 unit has all the fuel in the spent fuel tank. The Nos. 5 and 6 reactors achieved a state of "cold shutdown," helped by one emergency diesel generator which escaped being flooded.

Nuclear accident inspection must give public a fair view of Fukushima crisis

A report on the nuclear crisis at the Fukushima No. 1 Nuclear Power Plant **that the government has compiled** ahead of this month's International Atomic Energy Agency ministerial conference has unveiled 28 lessons from the crisis. Many of these lessons had already been pointed out by experts and the media, but the government had not officially acknowledged them.

The report stated that measures to prevent serious nuclear accidents such as those involving the meltdown of reactor cores had been left up to the discretion of nuclear power companies. Furthermore, guidelines on how to handle accidents had not been revised for nearly 20 years and training was insufficient, the report said.

Probabilistic risk assessment was often carried out but measures were not put into effect. Furthermore, monitoring of radiation after the accident and the supply of information was insufficient. It was also pointed out that the government's system for predicting radioactive substance doses, known as SPEEDI, was not effectively used.

Considering the government's admission of such problems and its call for boosted countermeasures, the report could be regarded as a step forward in Japan's inspection of the nuclear crisis. But insufficiencies in the government's analysis remain.

For example, what caused the delays in Japan's response to the crisis, and what lessons can be learned from these delays? How greatly was the public disadvantaged through radiation exposure or other problems stemming from insufficient information?

It is only natural that the Nuclear and Industrial Safety Agency (NISA) be made independent from the Ministry of Economy, Trade and Industry, but asking what role the Nuclear Safety Commission of Japan has played is surely also important when thinking about a system for future safety regulations.

We must remember that the report is only a provisional assessment by the government. Its content should be examined by the independent accident investigation and inspection committee that is probing the crisis.

During the first meeting of the committee, Prime Minister Naoto Kan stated, "The government will not ask you to proceed in a particular direction. We will supply everything that we are asked for." It is important for the committee to proceed with a completely independent and open investigation without making presumptions, taking the government's report as just one source of information. And the government should give 100 percent cooperation.

Worthy of note is the fact that the head of the accident investigation and inspection committee, Yotaro Hatamura, has stated, "The energy density of nuclear power is extremely high and dangerous, and I think it is a mistake that it has been considered safe up until now."

We want the committee to go about its inspection work with this kind of harsh view, working back to the foundations of nuclear power plants. The inspections are not something concerning the Fukushima No. 1 plant alone; they extend to nuclear power plants all over Japan, and, one might say, across the world.

Japan must now proceed with public debate on the nation's policy on nuclear power plants. Inspections of the accident will form the foundation for that debate, so the committee must do its utmost to provide sufficient material for judgment.

(Mainichi Japan) June 8, 2011

Fisheries Agency opposes Fukushima Daiichi nuke plant water release plan

TOKYO, June 8, Kyodo

Tokyo Electric Power Co.'s plan to release water containing traces of radioactive materials from the tsunami-hit Fukushima Daiichi nuclear power plant to the sea has been stopped due to stiff opposition from the Fisheries Agency, sources close to the matter said Wednesday.

Although the utility known as TEPCO told the agency that it will release the water after removing radioactive substances to an undetectable level, the agency is not approving the plan, **leaving the fate of the 3,000 tons of the water accumulated in the nuclear power station, located 15 kilometers south from the crippled Fukushima Daiichi power plant, undecided.**

If the water remains in tanks for a prolonged time, the storage facility may be corroded by salt in the water.

Fisheries Agency opposes Fukushima Daiichi nuke plant water release plan

TOKYO (Kyodo) -- Tokyo Electric Power Co.'s plan to release water containing traces of radioactive materials from the tsunami-hit Fukushima Daiichi nuclear power plant to the sea has been stopped due to stiff opposition from the Fisheries Agency, sources close to the matter said Wednesday.

Although the utility known as TEPCO told the agency that it will release the water after removing radioactive substances to an undetectable level, the agency is not approving the plan, **leaving the fate of the 3,000 tons of the water accumulated in the nuclear power station, located 15 kilometers south from the crippled Fukushima Daiichi power plant, undecided.**

If the water remains in tanks for a prolonged time, the storage facility may be corroded by salt in the water.

After being flooded by tsunami following a magnitude 9.0 earthquake that struck northeastern Japan on March 11, the Fukushima Daiichi power station saw about 7,000 tons of water accumulate in its facilities.

Of the water, 3,000 tons in the reactor, turbine and other buildings has been found to contain a small amount of radioactive materials such as cobalt.

TEPCO initially planned to let the water stay in the tank, but changed its mind after seeing rust in the storage facility and decided to release the water into the sea.

The level of radioactive materials detected in the water is below the legal standard for releasing such water to the environment. [encore une fois, peut-on se permettre de dire qu'il y a des seuils de radioactivité non dangereux ?]

To seek acceptance of its plan, TEPCO told the Fisheries Agency and local fishermen it would further clean the water with a mineral called zeolite before releasing it.

The agency declined to comment on the matter.

At TEPCO's Fukushima Daiichi power plant, which lost many of the key functions to keep nuclear fuel cool in the wake of the natural calamities, highly contaminated water was found to have leaked into the sea.

The utility has also released water with a low level of contamination in line with its plans to deal with the nuclear crisis.

The moves raised concerns over its effects on fisheries and TEPCO's unilateral notice on the releases to local fishermen drew public criticism.

Blackout hits Fukushima nuclear plant's Nos. 1, 2 units

Wednesday 08th June, 06:59 PM JST

Print

TOKYO —

The crippled Fukushima Daiichi nuclear power plant suffered power outages at its Nos. 1 and 2 reactors temporarily Wednesday, with lights in the units' central control room being cut off and the transmission of radiation data being partially halted.

The operator, Tokyo Electric Power Co, said the blackout did not affect its water injecting operation to cool the reactors, while Goshi Hosono, an adviser to Prime Minister Naoto Kan on the radiation leakage crisis, said the incident did not affect any equipment that could have caused an extremely serious situation.

Electricity was restored around 5:30 p.m., TEPCO said, adding that it is investigating the cause of the power outage.

The company said it found that a power panel linked to locations including the Nos. 1 and 2 reactors' central control room did not work at around 2:30 p.m.

The system to transfer data from radiation monitoring posts was found to have partly stopped. The blackout is also believed to have affected the nitrogen supply system for the No. 1 unit's containment vessel so its operation was stopped manually.

TEPCO is investigating whether the blackout damaged measuring equipment and affected its monitoring system of abnormalities.

Also Wednesday, TEPCO revealed a plan to leave a door linking the reactor and turbine buildings of the No. 1 unit open to reduce humidity in the reactor buildings later this month and help improve work efficiency within them.

Since radioactive materials within the reactor building could leak to the outside through the opened door, the Nuclear and Industrial Safety Agency, the government's nuclear safety agency, has instructed the utility to report the expected effects of the move on the environment by June 15.

At the No. 2 unit, the level of humidity has been high due to what appeared to be evaporation of water in a spent fuel pool of the reactor building and radioactive contaminated water believed to have accumulated in the building's basement. The humidity has hampered piping and data measuring work there.

Strontium contamination found outside nuclear crisis exclusion zone

Radioactive strontium 89 and strontium 90 has been detected in 11 locations outside the 20-kilometer exclusion zone around the crisis-stricken Fukushima No. 1 Nuclear Power Plant, the government announced June 8.

The radioactive isotopes of strontium are thought to cause bone cancer and leukemia. However, the Ministry of Education, Culture, Sports, Science and Technology has said the amounts detected are miniscule, and present no threat to human health.

The science ministry took soil samples in areas around the Fukushima plant from late March through early May. The highest strontium contamination outside the exclusion zone was found 29 kilometers west northwest of the plant in the town of Namie, with 1,500 becquerels of radiation from strontium 89, and 250 becquerels from strontium 90 per 1 kilogram of soil.

The second-highest contamination was found 36 kilometers northwest of the plant in the village of Iitate, with 1,100 becquerels of strontium 89, and 120 of strontium 90. The furthest from the plant strontium was detected was 62 kilometers away in the city of Fukushima, which registered 54 becquerels of strontium 89 and 7.7 becquerels of strontium 90.

The science ministry had previously detected strontium in three locations outside the 30-kilometer indoor standby order zone, and in four locations inside the exclusion zone.

TEPCO to test new water treatment system Fri. in Fukushima crisis

TOKYO (Kyodo) -- Tokyo Electric Power Co. plans to begin testing a newly installed radioactive water treatment system at its troubled Fukushima Daiichi nuclear power plant Friday, to deal with the massive amount of contaminated water that has hampered crisis control, a government regulator said Thursday.

The roughly weeklong trial run will precede a planned full operation of the system from mid-June to remove highly radioactive materials from the water accumulating at reactor facilities to eventually recycle it for cooling crippled reactors.

The government's Nuclear and Industrial Safety Agency said it is evaluating the plant operator's plan, adding that it hopes to approve the move by the end of the day.

With **highly radioactive water likely continuing to leak from damaged reactors**, the planned launch of the decontamination process has been an urgent task as the operator, known as TEPCO, seeks to restore stable cooling functions for the reactors.

The plant in Fukushima Prefecture has been critically damaged since the March 11 quake and tsunami knocked out its power.

During the trial run, low-level radioactive water that has been kept at a tank on the plant premises will be sent into the new installation to see if it can **remove radioactive cesium and other contaminants from the water, lower its radiation levels and desalinate it.**

TEPCO wants to process a total of roughly 250,000 tons of highly radioactive water at the new facility by the end of next March.

TEPCO also began testing seawater treatment equipment in the sea near the plant Thursday for removing leaked radioactive cesium, with plans to begin full operations after monitoring the trial run for two to three days.

To help slow the spread into the Pacific Ocean of the highly tainted water that leaked from around seawater intakes for the plant's Nos. 2 and 3 reactors, TEPCO has so far installed fences around the intakes.

(Mainichi Japan) June 9, 2011

FUKUSHIMA, Japan, June 9 (AP) - (Kyodo)—The Date city office in Fukushima Prefecture said Thursday it will distribute dosimeters to all children attending preschool as well as elementary and junior high schools in the city amid growing worries over exposure to radiation from the crippled Fukushima Daiichi nuclear power station nearby.

The city said the distribution of about 8,000 dosimeters will be part of its efforts to ensure children's health as there are radiation "hot spots" in the city, which is adjacent to Iitate, which is within a government-set evacuation zone.

The Fukushima Daiichi plant, southeast of Date, has been crippled since the March 11 quake and tsunami knocked out its power, triggering the country's worst ever nuclear crisis.

Blackout hits Fukushima nuclear plant's Nos. 1, 2 units

TOKYO (Kyodo) -- The crisis-hit Fukushima Daiichi nuclear power plant suffered power outages at its Nos. 1 and 2 reactors Wednesday, with lights cut off in the units' central control room, and water level and pressure indicators for one of the reactors out of service for more than three hours.

The plant's operator, Tokyo Electric Power Co., said the blackout did not affect its water injection operation to prevent the crisis from worsening and no evidence of abnormalities was found in data on the No. 2 reactor after power was restored in the evening, but the government urged the utility again to diversify power sources at the six-reactor complex.

The power outage occurred around 2:20 p.m. and electricity began to be restored around 5:30 p.m., the utility known as TEPCO said, adding that it is investigating the cause of the incident.

The plant in Fukushima Prefecture has been crippled since the March 11 quake and tsunami knocked out its power, triggering the country's worst nuclear crisis.

The utility said it found that a power panel linked to locations including the Nos. 1 and 2 reactors' central control room had stopped working around 2:30 p.m.

A system to transfer data from radiation monitoring posts was found to have partially stopped. The blackout also affected the nitrogen supply system for the No. 1 unit's containment vessel aimed at preventing a hydrogen explosion, prompting the operator to stop it manually.

Also Wednesday, TEPCO revealed a plan to leave a door linking the reactor and turbine buildings of the No. 2 unit open later this month to reduce humidity in the reactor building and help improve the efficiency of work in them.

Since radioactive materials within the reactor building could leak to the outside through the open door, the government's Nuclear and Industrial Safety Agency has instructed the utility to report on the expected environmental effects of the move by June 15.

The high level of humidity at the No. 2 unit is apparently due to the evaporation of water from a spent fuel pool in the reactor building and radioactive water believed to have accumulated in the building's basement. The humidity has hampered piping and data measuring work there.

TEPCO also said its President Masataka Shimizu took Masao Yoshida, chief of the crippled plant, to task Monday for not reporting to the head office until late last month that he had ordered the continuation of seawater injections into one of the plant's troubled reactors on March 12.

The delay in notifying the utility's head office led TEPCO to erroneously announce that the injection of water had been suspended for 55 minutes. But the utility said it judged that Yoshida's order in itself was appropriate.

(Mainichi Japan) June 9, 2011

Radiation leaking from Fukushima power plant should be monitored more closely

Residents of the Tokyo metropolitan area are becoming increasingly concerned about levels of radiation spreading to their neighborhoods from the tsunami-hit Fukushima No. 1 Nuclear Power Plant.

There are some areas called "hot spots," where high levels of radiation have been detected even though they are far away from the crippled nuclear plant. When radioactive substances leak from a nuclear facility as a result of an accident and spread through the sky, they fall on some limited areas depending on geographical features, wind direction and rain, resulting in high concentration of radiation in these areas.

Following the Chernobyl nuclear crisis that was ranked level 7 -- the worst level equal to the Fukushima crisis -- an area nearly 300 kilometers away from the plant was contaminated with high levels of radiation, forcing authorities to relocate local residents.

Municipal governments in Matsudo and five other cities in northwestern Chiba Prefecture requested the prefectural government to monitor radiation levels and release the results on the grounds that some data shows comparatively high levels of radiation in the area. The prefectural authorities complied, and conducted measurements of radiation levels in these cities.

The six municipal governments are urging the prefectural government to continue to regularly monitor radiation dosages in these areas, and to have the data examined by a working group that includes experts.

In Chiba Prefecture, high levels of radioactive substances in excess of the legal limits have been detected in spinach and some other locally grown vegetables.

A private organization that monitored radiation levels in Tokyo detected higher amounts of radiation than Tokyo Metropolitan Government official data. Residents of the 23 wards in central Tokyo and cities in the Musashino district in western Tokyo have voiced concerns about their exposure to radiation, prompting many of these municipalities to launch or plan measurements of radiation levels. Similar moves are spreading in neighboring Kanagawa and Saitama prefectures.

The Education, Culture, Sports, Science and Technology Ministry has commissioned all of the nation's 47 prefectural governments to monitor radiation levels, but monitoring is conducted at only one location in each prefecture. Apart from this, only figures released by universities and data around the crippled nuclear plant are available.

On the other hand, observations by the government's System for Prediction of Environmental Emergency Dose Information hint at the possibility that on the morning of March 15 -- when it is estimated that the largest amount of radioactive substances were released from the Fukushima plant since the crisis began -- such substances were likely to have spread toward the Kanto region around Tokyo.

Even experts are divided over the levels of radiation that could cause health hazards. Therefore, it is only natural that members of the general public wonder which standards they should believe. Some have expressed anxiety over possible contamination of water in swimming pools, which they fear could affect their children's health, as summer approaches.

Local governments must be sensitive about their residents' anxiety and proactively monitor radiation levels in a bid to relieve them. If specific and detailed data is released, individual residents can use the figures to try to reduce their exposure to radiation.

However, **most municipal governments neither employ radiation experts nor have the expertise or equipment to monitor radiation levels.** The Education, Culture, Sports, Science and Technology Ministry says it intends to take action to monitor radiation levels and to reduce it in so-called "hot spots" if requested by a growing number of local residents. However, the national government is primarily responsible for responding to crises at nuclear power plants. It should step up its monitoring of radiation levels and set clear standards for monitoring methods employed by different organizations, which critics say vary from entity to entity. Prefectural governments should also proactively get involved in such efforts.

Shareholders urge TEPCO to give up nuclear power

TOKYO, June 10, Kyodo

A group of 402 shareholders of Tokyo Electric Power Co. has urged the utility to give up nuclear power generation, the company, known as TEPCO, said Friday.

The request has been submitted as a proposal to be discussed at the annual shareholders meeting on June 28 in the wake of the nuclear emergency at the utility's Fukushima Daiichi power plant.

TEPCO said its board of directors will oppose the proposal for a change in the company's articles of incorporation to seek the withdrawal from nuclear power generation.

Selon TEPCO, les résidus(les boues ??) de l'eau contaminée seront saturés de substances radioactives.

TEPCO n'a en fait aucune idée de la façon dont ils vont pouvoir stocker des résidus. Ils n'ont pas non plus prévu de site qui pourrait servir de décharge définitive. Ils comptent sur l'expérience de Kurion (USA) et Areva (France), mais même Areva reconnaît qu'ils n'ont jamais eu à traiter des résidus émanant du traitement d'eau contaminées qui émet plus de 1000 millisieverts/heure.

TEPCO pense qu'il restera environ 2000 m3 de résidus, après traitement de l'eau. Ils ont sur place une installation de stockage mais qui ne pourra recueillir que 1200 m3. Il va donc falloir en construire une autre ; avec quels matériels ?? TEPCO admet ne pas le savoir.

Sludge from contaminated water would be packed with radioactive substances: TEPCO

Sludge that will be generated in the process of treating radioactive water at the tsunami-hit Fukushima No. 1 Nuclear Power Plant is estimated to contain **100 million becquerels of radioactive substances per cubic centimeter**, the plant operator said.

Tokyo Electric Power Co. (TEPCO) made the estimation in a report on the water treatment system submitted to the government's Nuclear and Industrial Safety Agency (NISA).

While trying to begin treating the increasing volumes of radioactive water at an early date, **TEPCO has failed to indicate how it will store the toxic sludge or a final disposal site** in its road map to bring the crippled plant under control.

TEPCO will launch treatment of the radioactive water on June 15 at the earliest. Specifically, it will use **special equipment produced by Kurion Inc. of the United States and France-based Areva** -- which have broad experience removing radioactive substances -- to separate sludge contaminated with radioactive substances from the water. The sludge is expected to contain such high levels of radiation because radioactive substances in it will be condensed.

TEPCO estimates that about **2,000 cubic meters of sludge** will be generated through the treatment of radioactive water at the plant by the end of this year, and intends to keep the toxic substance in the plant's intensive radioactive waste disposal facility.

However, the facility can only hold 1,200 cubic meters of the sludge because radioactive waste generated in the plant's ordinary operations is already kept there, forcing the utility to build a new facility to keep the sludge on the plant premises.

However, because it is so highly radioactive, the sludge is extremely difficult to manage. **Areva acknowledges that it has never handled sludge generated through the treatment of water emitting more than 1,000 millisieverts of radiation per hour.**

While radioactive waste generated in the plant's ordinary operations is regularly transferred to a reprocessing plant in Rokkasho, Aomori Prefecture, **the final disposal site for the sludge and other waste generated as a result of the Fukushima nuclear disaster has not been determined.**

NISA councillor Hidehiko Nishiyama fears it will take a long time to establish the radioactive sludge treatment process.

"Since such sludge has never been generated in Japan, the treatment technology must be created from scratch, from the research and development phase," he says. "It will likely take a long time, considering the safety regulations need to be enforced, development of an actual treatment method, and legal procedures."

Junichi Matsumoto, a high-ranking TEPCO official, also admitted that it will need to develop treatment methods. "We haven't decided how to produce containers for the sludge, or how to treat it," he said.

(Mainichi Japan) June 10, 2011

2 TEPCO workers confirmed with radiation doses more than twice limit

TOKYO (Kyodo) -- The government's nuclear agency said Friday two Tokyo Electric Power Co. employees working at the Fukushima Daiichi nuclear power plant have been confirmed as having received radiation doses more than twice the limit and that it had rebuked the company over the matter.

As for the ongoing work to restore the crippled plant, the utility known as TEPCO planned to test-run on Friday a system intended to clean up highly radioactive water that is accumulating at the site, but postponed it because water leaks were found in equipment.

The operation of the system is seen as crucial to containing the nearly three-month-old nuclear crisis, as the decontaminated water is eventually expected to be recycled as a coolant for the reactors, which lost their cooling functions as a result of the March 11 earthquake and ensuing tsunami.

Water has been injected into the plant's Nos. 1 to 3 reactors to keep the nuclear fuel cool, but a large part of the water, contaminated with radioactive substances, has apparently leaked out into the reactor turbine buildings and nearby areas.

Thousands of workers have entered the plant to grapple with the country's worst nuclear accident, with the government raising the legal limit on the amount of radiation to which each worker can be exposed from 100 millisieverts to 250 millisieverts exclusively for the Fukushima crisis.

But TEPCO was found to have allowed two of its workers to be exposed to 678 millisieverts and 643 millisieverts, respectively. Their internal exposure was 590 millisieverts and 540 millisieverts.

TEPCO also said another male employee may have been exposed to radiation above the limit.

The Nuclear and Industrial Safety Agency said it ordered the utility to find out how the two workers' radiation exposure occurred and report preventive measures to the agency.

Agency spokesman Hidehiko Nishiyama said no problems had been found during health checks on the two workers, but noted the state would continue to check their health conditions.

TEPCO, meanwhile, sent workers to the upper floors of the building housing the No. 4 reactor to gear up for the creation of a system to efficiently cool the spent nuclear fuel pool inside, according to Nishiyama.

The No. 4 reactor was under maintenance at the time of the earthquake and all of its fuel is in the spent fuel tank, where water is now being periodically poured from outside because the tank also lost its cooling function.

(Mainichi Japan) June 11, 2011

TEPCO starts ventilating No. 2 reactor to lower radiation levels

Japanese firm starts ventilating reactor to lower radiation level

Saturday June 11, 2011 04:31:37 EDT

Tokyo, Jun 11, 2011 (BBC Monitoring via COMTEX News Network) --

Tokyo Electric Power Co. said **on Saturday it began operating ventilation equipment at the No. 2 reactor building of the crippled Fukushima Daiichi nuclear power plant to reduce radiation levels inside the unit.**

If airborne radioactive materials are fully removed after running the equipment for three days, the utility known as TEPCO plans to open the doors of the reactor building and begin work inside the unit.

Highly radioactive materials and high humidity inside the building have prevented workers from entering the site to check measuring gauges and conduct piping work, hampering efforts by the utility to eventually bring the reactor to a stable cold shutdown.

The ventilation equipment has filters to absorb radioactive materials.

TEPCO starts ventilating No. 2 reactor to lower radiation levels

TOKYO, June 11, Kyodo

Tokyo Electric Power Co. said Saturday it began operating ventilation equipment with filters to absorb radioactive materials to reduce radiation levels inside the No. 2 reactor building of the crisis-hit Fukushima Daiichi nuclear power plant to pave the way for restoration work inside.

As earlier ventilation of steam at the plant is blamed for widely spreading radioactive substances outside, the government's nuclear safety agency is considering requiring that boiling-water reactors across Japan have steam-venting pipes equipped with filters to remove such toxic substances.

At the Fukushima plant's No. 2 reactor, highly radioactive materials and high humidity inside the building have prevented workers from entering the site to check measuring gauges and conduct piping work, hampering efforts by the utility to stabilize the reactor.

Japan needs to dispose nuke waste, tainted debris in Japan: Hosono

Saturday, June 11, 2011 12:59

No.2 reactor air filter starts running

The operator of the Fukushima Daiichi nuclear plant has begun running air-filtering equipment at the Number 2 reactor building on Saturday to remove airborne radioactive material.

Intense radioactivity and high humidity inside the building have been hampering work to restore the reactor's cooling system.

Humidity inside the reactor building is as high as 99.9 percent due to moisture that is believed to have come from a spent nuclear fuel storage pool and the basement. Workers cannot remain in the building for a long time even with protective gear and masks.

Tokyo Electric Power Company had set up 2 air-filtering units at a building adjacent to the reactor building. The devices will filter radioactive materials out of air pumped from the reactor building through a duct. The cleaned air will be fed back into the reactor building.

TEPCO says it plans to run the devices for about 3 days and check internal radiation levels before opening up the doors of the reactor building.

Ex-adviser raps gov't for worsening local residents' radiation exposure

TOKYO (Kyodo) -- A report by a former government adviser on the nuclear crisis at the Fukushima Daiichi power plant, obtained Friday, criticized the government for exacerbating the radiation exposure of local residents due to what he called its **impromptu initial handling of the crisis**.

Toshiso Kosako, professor on radiation safety at the University of Tokyo's graduate school, said in the report submitted to Prime Minister Naoto Kan just before he stepped down as adviser in late April that **the government had failed to make efficient use of forecasts on the spread of radioactive substances from the Fukushima plant**.

In criticizing the government's impromptu handling of the crisis in its early stages, Kosako in the report, a copy of which was made available to Kyodo News, cited a lack of leadership at the premier's office and the Nuclear Safety Commission's uncooperative attitude toward the adviser's team.

He said the government had delayed the release of forecasts on the spread of radiation from the Fukushima plant compiled by the Nuclear Safety Technology Center's computer system, called the System for Prediction of Environmental Emergency Dose Information, or SPEEDI.

He also said **an epidemiological study should be conducted in Fukushima and neighboring prefectures as thyroid cancer is expected to develop among children**.

Kosako drew up the report dated April 27, two days before he said he would step down, as an unofficial record of the activities of his team.

After the March 11 earthquake and tsunami triggered the country's worst nuclear crisis, Kosako assumed the post on March 16 with the duty of advising Kan on matters related to nuclear power plants and radiation.

The report said **the adviser's team gave more than 60 pieces of technical advice but the government failed to make use of most of them promptly and effectively**.

On local residents' exposure to radiation, the government said in a report submitted Tuesday to the International Atomic Energy Agency that nearly 200,000 people in Fukushima Prefecture had undergone screening tests and no health problems had been found.

The government also said only low-level radioactivity was detected in thyroid examinations of around 1,000 children.

Centrales nucléaires : des salariés inquiets d'une hausse des cadences

LEMONDE.FR | 11.06.11 | 18h20

Dans les centrales nucléaires, les arrêts de tranche sont essentiels à la sûreté des installations. En France, ils ont lieu au moins une fois par an pour les arrêts simples, tous les dix ans pour les visites décennales. Ces arrêts d'une durée de un à trois mois permettent d'effectuer des opérations de maintenance, de renouveler une partie du combustible présent dans les réacteurs et de contrôler l'ensemble des installations.

Une note interne d'EDF, révélée samedi 11 juin par [Le Parisien - Aujourd'hui en France](#), préconise d'augmenter les cadences pendant les arrêts de tranche, afin d'en réduire la durée. Car un arrêt de tranche signifie un arrêt de la production d'électricité. Dans un courrier daté du 10 mai, signé par le directeur adjoint de la production nucléaire d'EDF, [Philippe Druelle](#), il est demandé aux directeurs de centrale de "demander des dérogations aux durées maximales de travail auprès des inspecteurs du travail" ou de la Direction régionale du travail.

"Il a été convenu que les périodes d'arrêt de tranche sont des périodes de surcroît d'activité (...). Ce surcroît d'activité nous permet de justifier des demandes de dérogations aux durées maximales du travail (journalières et hebdomadaires)", relève ce courrier. Cette préconisation qu'EDF souhaiterait appliquer "d'ici l'été 2011" provoque l'inquiétude des salariés, qui estiment qu'elle pourrait nuire à la sûreté des installations. *"EDF s'organise pour légaliser des dérives horaires inacceptables et dangereuses pour les salariés et donc la sûreté nucléaire",* met en garde la CGT.

Pour EDF, *"il s'agit d'un malentendu"*. [Bernard Lassus](#), directeur des ressources humaines du groupe, interrogé par *Le Parisien*, assure que l'objectif d'EDF est de *"clarifier l'organisation du travail"*, de façon à *"permettre aux cadres de prendre leur repos journalier de 11 heures"*.

"LE RACCOURCISSEMENT DES DÉLAIS NE SE FAIT PAS SANS PRIX"

En avril, un mécanicien sous-traitant travaillant dans la centrale de Dampierre – qui avait souhaité garder l'anonymat – avait confié au Monde.fr son [inquiétude face à l'accélération des rythmes de travail](#) pendant les arrêts de tranche. *"Il y a vingt ans, ces arrêts duraient trois mois. Aujourd'hui, ils durent trois semaines en moyenne. Et ce raccourcissement des délais ne se fait pas sans prix. EDF met la pression sur les sous-traitants. De plus en plus, nous travaillons les week-ends et enchaînons les semaines sans prendre de repos. Il arrive parfois que nous maquillions nos heures pour ne pas dépasser la limite légale des quarante-huit heures de travail hebdomadaire."*

Le directeur de la centrale de Dampierre, [Eliau Bossard](#), avait alors justifié le raccourcissement des arrêts de tranche par une amélioration de l'expertise des équipes. *"Forts de notre expérience, nous améliorons nos pratiques de gestion et nous impliquons nos prestataires dans la préparation des arrêts,* expliquait-il. *Il faut compter entre six et huit mois de travail en amont pour préparer toutes les interventions."* Mais une [vidéo](#) du comité central d'entreprise d'EDF tournée en 2002 lors d'un forum sur les conditions de travail dans les centrales, et publiée par Mediapart, soulignait les risques des arrêts de tranche "optimisés" : *"On multiplie le nombre de prestataires à l'intérieur du bâtiment réacteur et tout le monde se marche dessus"*, notait un délégué syndical CGT de la centrale de Cattenom, en Moselle.

Water treatment system testing at Fukushima plant hits snag again

TOKYO, June 12, Kyodo

Tokyo Electric Power Co.'s preparations to begin testing a newly installed radioactive water treatment system at its troubled Fukushima Daiichi nuclear plant hit a snag again as **the piping may be clogged**, company officials said Sunday.

The utility initially planned to begin the tests for the system, intended to decontaminate highly radioactive water that is accumulating at the site and hampering work to restore the damaged plant, last Friday, but postponed it because water leaks were found in the equipment that day.

Repairs to fix the water leaks were completed by Sunday and the firm, also known as TEPCO, was getting ready to conduct the tests. But the fresh problem is likely to cause a delay in the company's plan to put the system in full operation from mid-June, as the trial run using low-level radioactive water is expected to last about a week.

Radioactive water treatment likely to be delayed

Treatment of highly radioactive water at the troubled Fukushima Daiichi nuclear power plant is likely to be delayed by a problem with the flow of water.

The system being installed at the plant includes a device to remove cesium using zeolite, as well as equipment that settles out radioactive substances using specialized chemicals.

Tokyo Electric Power Company, or TEPCO, said on Sunday that it has found that water does not flow in one of the 4 units as expected.

TEPCO had planned to start a test-run of the device on Friday, but it was postponed after the firm found another problem, which needed repairing first.

The operator hopes that the system will lower the concentration of radioactivity and expects to treat 1,200 tons of radioactive water a day.

TEPCO is trying to identify the cause of the problem.

Mass demonstrations against nuclear power held in Japan 3 months after quake

TOKYO (AP) -- Protesters held mass demonstrations against nuclear power across Japan on Saturday, the three-month anniversary of the powerful earthquake and tsunami that killed more than 23,000 people and triggered one of the world's worst nuclear disasters.

Streets in parts of Tokyo were completely jammed with thousands of chanting protesters, paralyzing sections of the city. Some marchers called for the country's nuclear plants to be shut down immediately and for stricter radiation tests by the government.

The magnitude-9 earthquake that hit March 11 off Japan's northeast coast caused a massive tsunami that devastated the coastline. The disasters knocked out power and cooling systems at the Fukushima Dai-ichi nuclear power plant, about 225 kilometers northeast of Tokyo, setting off explosions, fires and large radiation leaks at the facility.

Government reports released earlier in the week said the damage and leakage were worse than previously thought, with some of the nuclear fuel in three reactors likely having melted through the main cores and inner containment vessels. They said the radiation that leaked into the air amounted to about one-sixth of the Chernobyl nuclear disaster in 1986 -- double previous estimates.

The disasters have renewed a national debate on nuclear power in Japan, which has few natural resources. Japan relied on nuclear energy for 30 percent of its electricity before the disasters and planned to raise that to 50 percent by 2030, but the government has announced it will abandon that target and promote renewable energy instead.

"Since the earthquake, I've realized that nuclear power is just too dangerous for use," said Takeshi Terada, 32, a shipping worker who marched with 10 friends in Tokyo.

Some nuclear plants across the country remain shut in the wake of the disaster, leading to fears Tokyo and other areas may not have enough electricity for the peak summer months. Residents of the capital are reducing their use of lights and air conditioning, and some companies are moving crucial operations like computer centers to parts of Japan with more stable power supplies.

At the Fukushima plant, hundreds of workers are still struggling to bring the crippled reactors to a "cold shutdown" by early next year and end the crisis. Radiation fears have forced more than 80,000 people to evacuate from their homes around the plant.

Many more people have had to leave their homes along the northeast coast because of tsunami damage. Three months after the disasters, 90,000 are still living in temporary shelters such as school gyms and community centers.

Along the tsunami-ravaged coast Saturday, residents bowed their heads in a moment of silence at 2:46 p.m., when the earthquake struck.

Embattled Japanese Prime Minister Naoto Kan visited Kamaishi, a hard-hit coastal city. Kan has been under fire for his handling of the disasters and the country's recovery plans, surviving a no-confidence vote earlier this month by promising to step down once the recovery takes hold.

Speculation about when he will quit has been rampant, with his party and the main opposition hinting at a coalition to speed the recovery. But Kan's visit Saturday was seen by some as a suggestion he will attempt to prolong his tenure.

"It is not just a matter of listening to what people say at the destroyed areas. I want to incorporate what I hear into government measures," he said.

In Tokyo, protesters carried colorful banners and banged drums as they walked in orderly rows past the Economy Ministry and the head offices of Tokyo Electric Power Co., which operates the Fukushima plant. Entire families marched, their toddlers and even dogs wearing clothing with anti-nuclear slogans.

"I'm worried about the children. It's not just in Fukushima, there are radiation problems even here in Tokyo," said Mika Obuchi, 45, who marched with her husband and 9-year-old daughter.

Shareholders propose Kansai Electric give up nuclear power

OSAKA, June 12, Kyodo

A group of 124 shareholders of **Kansai Electric Power Co.** have proposed that the utility give up nuclear power generation in light of the ongoing nuclear crisis at Tokyo Electric Power Co.'s Fukushima Daiichi plant, sources close to the situation said Sunday.

The development comes after Tokyo Electric said Friday that 402 of its shareholders have submitted a request to discuss at the firm's shareholders meeting on June 28 revising the utility's articles of incorporation to say that it will give up atomic power generation.

The group of Kansai Electric shareholders also presented a proposal of agenda items to be discussed at the utility's general shareholders meeting scheduled June 29 in Osaka, but the company's board of directors are opposed to such a move, the sources said.

TEPCO forced to review reactor 4 cooling plan

The operator of the Fukushima Daiichi nuclear power plant has been forced to reconsider its plan to cool the spent fuel storage pool of the No.4 reactor.

Water injection from a special vehicle has not been intense enough to cool the water in the pool, allowing the temperature to remain at more than 80 degrees Celsius.

Tokyo Electric Power Company, or TEPCO, aims to install a circulatory cooling system that will pump water out of the pool and return it there as coolant. The utility originally hoped to put the system in place next month.

On Friday, workers entered the 4th floor of the No.4 reactor building where the pool is located for the first time since the nuclear disaster took place.

They found a large hole in a wall created by the March 15th explosion. They also discovered that a nearby pipe necessary for the cooling system had been mangled.

TEPCO says the repair team found it hard to work near the pool as equipment had been destroyed and debris was scattered on the floor.

Fixing the damaged pipe is expected to be extremely difficult. In addition, it remains unclear if there is another pipe that can be used for the cooling system.

Sunday, June 12, 2011 11:00

Measures to prevent heatstroke to be added

The operator of the troubled Fukushima Daiichi nuclear power plant says it will implement measures to **prevent workers from being hit by heatstroke.**

About 2,500 people work at the plant. Many of them wear protective suits and full-face masks to lower exposure to high radiation.

But the work is getting tougher physically and mentally as summer approaches. So far, 12 workers have been diagnosed as suffering from heatstroke.

Tokyo Electric Power Company will set up 7 more rest areas in addition to the 8 existing ones.

Workers can take off the protective gear, drink water, and lie down there.

In addition, the company will supply 2,500 vests containing cooling gel which will be worn underneath the gear.

1,300 face masks which provide extra air during inhalation will be secured.

The health ministry had given instructions to the utility to improve working conditions.

High concentration of radioactive strontium found at Fukushima plant

TOKYO, June 12, Kyodo

Radioactive strontium **up to 240 times the legal concentration limit has been detected in seawater samples** collected near an intake at the crippled Fukushima Daiichi nuclear plant, Tokyo Electric Power Co. said Sunday.

The utility known as TEPCO said the substance was also found in groundwater near the plant's Nos. 1 and 2 reactors. The government's Nuclear and Industrial Safety Agency said it **is the first time that the substance has been found in groundwater**.

The agency said it is necessary to carefully monitor the possible effects of the strontium on fishery products near the plant.

High concentration of radioactive strontium found at Fukushima plant

TOKYO (Kyodo) -- **Radioactive strontium up to 240 times the legal concentration limit has been detected in seawater samples** collected near an intake at the crippled Fukushima Daiichi nuclear plant, Tokyo Electric Power Co. said Sunday.

The utility known as TEPCO said the substance was **also found in groundwater near the plant's Nos. 1 and 2 reactors**. The government's Nuclear and Industrial Safety Agency said it is the first time that the substance has been found in groundwater.

The agency said it is necessary to carefully monitor the possible effects of the strontium on fishery products near the plant.

Strontium tends to accumulate in bones and is believed to cause bone cancer and leukemia.

Meanwhile, TEPCO on Sunday completed preparations to begin testing a newly installed radioactive water treatment system at the Fukushima plant soon, after it finished fixing an adsorption device designed to remove radioactive substances, company officials said.

The utility is expected to begin testing the system, intended to decontaminate highly radioactive water that is accumulating at the site and hampering work to restore the damaged plant, as early as Monday. **The company is a couple of days behind the schedule to put the system into full operation, initially planned for June 15, it said.**

The utility's preparations to begin testing the system hit a snag Sunday as the amount of water run through the adsorption device was lower than planned, indicating the possibility that piping or other parts may be clogged. The planned level of water recovered later, it said.

The utility is investigating the cause of the snag, the officials said.

TEPCO initially planned to begin testing the radioactive water treatment system last Friday but postponed it because water leaks were found in the equipment that day.

The utility said that even if the start of the system's operation is delayed, it does not mean that leaks of contaminated water into the environment would occur "immediately." [ça nous rassure]

The operation of the system is seen as crucial to containing the three-month-old nuclear crisis, as the decontaminated water is expected to eventually be recycled as a coolant for the reactors, which lost their cooling functions as a result of the March 11 earthquake and ensuing tsunami.

Water has been injected into some of the reactors to keep the nuclear fuel cool, but vast pools of water containing large amounts of radioactive substances have been found on the plant's premises as a side effect of the water-injection measure.

The system, set up at a facility where the highly radioactive water from the Nos. 2 and 3 units has been transferred, is expected to be able to treat about 1,200 tons per day, reducing the concentration of radioactive substances to around one-thousandth to one-ten thousandth.

Excessive levels of strontium detected in seawater

Radioactive strontium that exceeds the government-set safety level was detected for the first time in sea water in the inlet next to the Fukushima Daiichi nuclear plant.

Tokyo Electric Power Company, or TEPCO, reported that strontium-90, at a level 53 times higher than the safety standard was detected in samples taken from inside an inlet used exclusively by the nuclear plant, on May 16.

TEPCO also said that strontium-90 was detected at a level 170 times higher than the standard in samples also taken on May 16, near the water intakes outside reactor number 2. At the reactor number 3 water intakes, the level was 240 times higher than the legal safety limit.

The Nuclear and Industrial Safety Agency says the result is not beyond their expectations because the substance was detected in an inlet used exclusively by the power plant. They say they will closely monitor the fish and shellfish in the affected area.

TEPCO announced that strontium-90 was also detected for the first time in ground water near the reactors' buildings.

A ground water sample taken on May 18, around reactor number 2, measured 6,300 becquerels per liter. And for reactor number one, the sample showed 22 becquerels.

TEPCO explained it usually takes about 3 weeks to analyze the samples.

With a comparatively long half-life of 29 years, radioactive strontium can accumulate in the bones if inhaled, and poses a risk of cancer.

Farmland in Fukushima no-go zone to be inspected

The national and prefectural governments are to begin inspecting farmland in the no-entry zone around the Fukushima Daiichi nuclear power plant next month.

Fukushima Prefecture says rice planting has been suspended in all areas within the 30-kilometer radius from the power plant. Shipments of agricultural produce from within the 20-kilometer radius no-entry zone also remain halted.

State and prefectural authorities say they decided to study soil in paddies and farmland within the no-go zone in response to growing calls by the residents who say they want to know what's become of their farmland.

The authorities have been carrying out inspections of soil samples within the 30-kilometer zone, **but have refrained from checking the soil within the no-entry zone.** [why ?]

Fukushima Prefecture says the results of the inspections will be utilized to determine whether farming can be resumed in these areas once the ongoing crisis at the power plant is contained.

TEPCO releases photo showing damage to No. 4 reactor building

A photograph provided by Tokyo Electric Power Co. shows the fourth floor of a building housing the No. 4 reactor at the Fukushima No. 1 Nuclear Power Plant at about 2 p.m. on June 10, 2011.

Tokyo Electric Power Co. (TEPCO) has released a photograph showing the damaged inside of the building housing the No. 4 reactor at its crippled Fukushima No. 1 Nuclear Power Plant.

In the photo, which was released on June 11, the pipes and walls near a power generator inside the structure are charred black, and rubble covers the floor.

Earlier the company had released footage showing work to remotely measure the temperature of the pool for spent fuel at the No. 4 reactor, but the latest photo marks the first time since the March 11 earthquake and tsunami for the company to release a picture showing the inside of the reactor building.

The No. 4 reactor was hit by a hydrogen explosion on March 15, as well as fires on two occasions. The generator in the structure was used for a reactor recirculation pump and is thought to be the source of the fires.

Disposal of nuclear waste should be made a top priority

In this June 9, 2011 photo released Saturday, June 11, 2011 by Tokyo Electric Power Co. (TEPCO), equipment inside the cesium absorption tower, part of the newly-built radioactive water processing facilities at Fukushima No. 1 nuclear power plant in Okuma, Fukushima prefecture, is shown. (AP Photo/Tokyo Electric Power Co.)

In the June issue of the monthly journal Sekai (The World), life scientist Keiko Yanagisawa argues that **nuclear power plants must not be operated as long as we do not know how to dispose of highly radioactive nuclear waste -- which can wreak havoc on human DNA .**

Tetsuzo Fuwa, chairman of the Japanese Communist Party (JCP), is of the same view. Reading over the column he wrote in the party's daily paper Akahata (Red Flag), his position is presented in clear, unambiguous language.

Both Fuwa and Yanagisawa are alarmed that as a result of having continued the operation of nuclear power plants without any waste disposal measures in place, highly radioactive spent fuel has accumulated to breaking point.

Spent fuel is much more dangerous than nuclear fuel that has not yet been used, and has the potential of reaching recriticality unless its temperatures are continually kept cool. Because spent fuel continues to emit radiation even after the rate at which it releases heat diminishes, it must be isolated from human life for hundreds of thousands of years.

Since such waste currently has no place to go, however, there is nowhere to keep it except in spent fuel pools at nuclear power plants. It was just recently that the revelation that the pool water vaporized at the stricken Fukushima No. 1 Power Plant, thereby possibly melting the spent fuel, made our blood freeze.

Last month, NHK rebroadcast the striking documentary "Into Eternity," about a spent fuel disposal facility currently being built in Finland. The first of its kind, the plan for the facility is to bury nuclear waste 500 meters underground, and isolate it from human life for the 100,000 years stipulated by EU safety rules.

We don't know what sort of civilization will exist in Finland or the rest of the world tens of thousands of years from now. Advanced civilizations may have fallen by then. At any event, how can we help our descendants understand that they must not dig into the ground? There's no really good way to go about it.

It goes without saying that the issue of nuclear waste should have been resolved before we began using nuclear energy to generate power. The building of nuclear waste disposal facilities had heretofore not been carried out in Finland or anywhere else.

Initially, Japan had planned to dispose of spent fuel in the depths of the sea, but after attracting much international criticism, decided instead to bury it underground. But no concrete decisions have been made, including what kind of facility it's going to be and where it will be located. Local municipalities are reluctant even to host regular garbage treatment centers. Nuclear waste? Forget about it.

When talks between Japan and the U.S to establish a waste disposal facility in Mongolia came to light, some people said that it was acceptable as long as Mongolia was all right with it. That misses the point, though, doesn't it?

From the shell heaps of prehistoric times to the local dumps of the Edo Period, human beings disposed of their own waste. Are we going to let go of that unbroken tradition of moderation because of our thirst for electricity? (By Micihio Ushioda, Expert Senior Writer)

(Mainichi Japan) June 13, 2011

6 more nuke plant workers exposed to radiation above limit: TEPCO

Shareholders propose Tohoku Electric give up nuclear power

SENDAI, June 13, Kyodo

Fukushima City to give dosimeters to 34,000 children from fall

FUKUSHIMA, Japan, June 14, Kyodo

The Fukushima city office in Fukushima Prefecture said Tuesday it will give dosimeters to all children attending preschools as well as elementary and junior high schools in the city amid growing concerns over exposure to radiation from the crippled Fukushima Daiichi nuclear power plant nearby.

According to the municipal office, it will hand out the gauges for three months from September to about 34,000 children as part of its efforts to ensure their health, while it will collect data once a month and examine the results in cooperation with medical institutions.

It will also distribute the gauges to parents with children under three years old at the request of the parents.

Italians' rejection of nuclear power expected to have repercussions in Japan

Italian voters adamantly said "no" to nuclear power generation in a referendum on June 12 and 13, a move likely to have repercussions in Japan, which is the centerpiece of the ongoing nuclear crisis that has added to the anti-nuclear power momentum in Europe.

In Japan, a referendum is to be called over constitutional amendments but cannot be held over issues like whether to resume operations of nuclear power plants, as seen in Italy. A senior official in the electric utility industry stresses that **the situation in Italy is different from that in Japan, saying, "Italy had already pulled out of nuclear power generation, so the circumstances are different from those in Japan, where nuclear power generation accounts for about 30 percent of total power output."**

By saying this, the official implied that the outcome would not be the same even if a similar referendum was called in Japan. Prime Minister Naoto Kan has also indicated that the operation of nuclear plants apart from Chubu Electric Power Co.'s Hamaoka Nuclear Power Plant -- which was suspended following a government request -- can be restarted once their safety is guaranteed.

However, public trust in the central government and utility companies, which have long propagated the myth of nuclear power plant safety, was undermined from its very foundations among residents in areas hosting such facilities in the wake of the accident at the Fukushima No. 1 Nuclear Power Plant.

Governors of prefectures that are home to nuclear power plants have also expressed their distrust. "Safety comes first before power supply for the moment," said Saga Gov. Yasushi Furukawa, while Aomori Gov. Shingo Mimura said, "While the government maintains that there are no safety concerns for resuming the operation of nuclear power plants, it has urged the Hamaoka power plant to suspend operations. It is hard to figure out what aspects of safety the government looked at and how it assessed them in making its decision."

For nuclear power plants under suspension for regular inspections and other reasons to restart their operations, they will need approval from the governors of prefectures hosting those facilities. The prevalence of the anti-nuclear power movement in Europe could likely raise further concerns over nuclear plants in Japan and affect governors' decisions.

In this March 24, 2011 file aerial photo taken by a small unmanned drone and released by AIR PHOTO SERVICE, damaged Unit 4 of the crippled Fukushima Dai-ichi nuclear power plant is seen in Okumamachi, Fukushima prefecture, northern Japan. (AP Photo/AIR PHOTO SERVICE)

Junko Edahiro, director of the Institute for the Study of Happiness, Economy, and Society, believes Italy's referendum results would affect the public in Japan.

"The move in Italy follows that of Germany and other countries in their serious attempts to break away with nuclear power generation. **The referendum results in Italy could prompt Japanese to wonder if they have seriously thought about nuclear power generation and acted appropriately,**" Edahiro said.

"The referendum has also indicated the possibility of a political system through which voters can **directly question crucial policy measures,**" she said, adding, "We in Japan would also be able to change the electric policy if we form and voice our own opinions about energy issues."

(Mainichi Japan) June 14, 2011

FOCUS: 1,400 Fukushima plant workers waiting for radiation exposure results

TOKYO, June 14, Kyodo

While authorities slammed Tokyo Electric Power Co. for exposing workers at its crippled nuclear power plant to radiation levels exceeding the allowable limit, particularly for internal exposure, around 1,400 of the company's workers are still waiting for detailed checkup results.

About **3,700 people** worked at the Fukushima Daiichi nuclear power plant in the period from the March 11 earthquake and tsunami to the end of that month, but **the utility had finished detailed checks for internal radiation exposure on only around 2,300 by late May.**

Hidehiko Nishiyama, a spokesman for the government's Nuclear and Industrial Safety Agency, said **one of the reasons for TEPCO's inability to provide swift checkups for its workers is that the utility does not have enough whole body counters -- dosimeters designed specifically to measure radioactivity levels within the human body.**

1,400 Fukushima plant workers waiting for radiation exposure results

In this May 10, 2011 file photo released by Tokyo Electric Power Co., workers check the status of the water level indicator at the Unit 1 reactor building at the Fukushima Dai-ichi nuclear power plant in Okuma town, Fukushima Prefecture, northeastern Japan.(AP Photo/Tokyo Electric Power Co., File)

TOKYO (Kyodo) -- While authorities slammed Tokyo Electric Power Co. for exposing workers at its crippled nuclear power plant to radiation levels exceeding the allowable limit, particularly for internal exposure, around 1,400 of the company's workers are still waiting for detailed checkup results.

About 3,700 people worked at the Fukushima Daiichi nuclear power plant in the period from the March 11 earthquake and tsunami to the end of that month, but **the utility had finished detailed checks for internal radiation exposure on only around 2,300 by late May.**

Hidehiko Nishiyama, a spokesman for the government's Nuclear and Industrial Safety Agency, said one **of the reasons for TEPCO's inability to provide swift checkups for its workers is that the utility does not have enough whole body counters -- dosimeters designed specifically to measure radioactivity levels within the human body.**

The situation poses a serious problem as the nuclear crisis, triggered by the earthquake and tsunami, is still unfolding and a large number of people are desperately working to bring the plant under control. Internal radiation exposure could increase the incidence of cancer and leukemia.

On June 3, two TEPCO employees working at the Fukushima Daiichi plant were confirmed as having received radiation doses of 678 millisieverts and 643 millisieverts, more than twice the legal limit of 250 millisieverts for people working dealing with the crisis.

The Health, Labor and Welfare Ministry said earlier this week that another six workers may have been exposed to excessive radiation.

In this May 15, 2011 photo released Friday, June 10, 2011 by Tokyo Electric Power Co. (TEPCO), workers take break in a temporary rest area at Fukushima Dai-ichi nuclear power plant. (AP Photo/Tokyo Electric Power Co.)

Each worker at the Fukushima plant wears a dosimeter to gauge external exposure and keeps a record everyday. **As for internal exposure, caused by the absorption of radioactive materials through the nose and mouth, workers normally undergo detailed tests every three months using a whole body counter.**

TEPCO had four such counters at the Fukushima Daiichi power plant, according to company officials. **But they were rendered useless once the crisis broke out because radiation levels at the plant became too high to accurately gauge whole body exposure,** they said.

TEPCO is currently conducting detailed checkups for people working at the plant using four whole body counters at a different facility, and **it will take several months before the utility can increase the number of counters to over 14.**

Given the situation, the utility reportedly placed priority on examining the internal exposure of 21 workers whose external exposure had exceeded 100 millisieverts, and 19 women, for whom a lower limit has been set, engaged in non-nuclear duties at the plant.

The two men who were confirmed on June 3 as having been exposed to high levels of radiation were not in the priority group, indicating **a substantial difference in the levels of external and internal exposure,** experts said.

The external exposure of one of the men was 88 millisieverts but his internal exposure was 590 millisieverts, while the external exposure of the other was 103 millisieverts but his internal exposure was 540 millisieverts, they said.

The experts fear that the current legal limit for workers at the Fukushima plant could be raised because the crisis is unlikely to end anytime soon and there is likely to be a shortage of workers possessing the requisite skills and knowledge.

The inside of the No. 2 reactor building at the Fukushima No. 1 Nuclear Power Plant on May 18. (Photo courtesy of TEPCO)

People working for TEPCO's subcontractors said radiation levels at the plant have fallen overall but there are areas with high levels where dosimeters can count 1 to 2 millisieverts within a couple of hours.

Some residents of Fukushima Prefecture have said they would also like to undergo whole body counter checks, but Goshi Hosono, special adviser to Prime Minister Naoto Kan, has said such **checkups for residents may not take place for some time as the government only possesses a limited number of whole body counters.**

(Mainichi Japan) June 15, 2011

Poor decisions leave TEPCO workers vulnerable to radiation

2011/06/15 <http://www.asahi.com/english/TKY201106140177.html>

Six more employees of Tokyo Electric Power Co. working at the Fukushima No. 1 nuclear power plant were exposed to more radiation than allowed even under the relaxed limits put in place to deal with the critical accident.

In addition, **102 workers** have been exposed to more radiation than allowed for nuclear power plant workers. Such workers are subsequently prohibited from working at nuclear power plants for up to five years **under normal circumstances.**

If more workers are discovered to have exceeded radiation exposure levels, **TEPCO may face a serious shortage of workers** even while the situation at the Fukushima plant is far from under control.

The government raised the upper limit for workers dealing with the Fukushima accident to 250 millisieverts. However, TEPCO announced June 13 that six additional employees had been exposed to more than that level of radiation. The company had previously announced that two employees had been exposed to more than 250 millisieverts.

What makes the situation serious for those six is that all have been exposed to more than 250 millisieverts through internal contamination by which they have inhaled the radiation.

The normal upper limit for workers at nuclear power plants is 100 millisieverts. TEPCO announced that a total of 102 employees had been exposed to more than that level.

TEPCO submitted a report to the Ministry of Health, Labor and Welfare on June 13 of a study into the 3,726 workers at the Fukushima No. 1 plant who worked between March 11, when the Great East Japan Earthquake struck, until March 31.

Of those workers, radiation exposure levels for 2,367 workers who were tested were reported to the labor ministry. The results of the study for the remaining workers will be submitted by June 20.

The eight workers found to have been exposed to more than 250 millisieverts were all male TEPCO employees.

The six employees who were added to the list in the latest report worked to restore equipment at the Fukushima plant as well as measure radiation levels.

The worker found to have the highest radiation exposure level was found to have been exposed to 497.6 millisieverts.

The labor ministry instructed TEPCO to remove a total of 12 workers exposed to more than 200 millisieverts from all emergency work at the Fukushima plant.

Of workers who were not exposed to more than 250 millisieverts, 23 were exposed to more than 100 millisieverts through internal contamination alone. A total of 94 workers were exposed to more than 100 millisieverts when internal and external contamination levels were combined.

Including the workers covered in the latest study, **a total of about 7,800 individuals have been working at the Fukushima No. 1 plant through late May to restore operations.**

The labor ministry has asked TEPCO to submit a report on total radiation exposure levels, including internal contamination, for all those workers by the end of June.

However, a problem for TEPCO is that the March 11 quake and tsunami devastated the systems to measure external and internal contamination levels.

Dosimeters at the Fukushima plant were damaged by the disasters so TEPCO had to borrow dosimeters from other nuclear plants. While that was completed in April, the company still has not installed enough equipment to test for internal contamination.

The local labor bureau has instructed TEPCO to improve its practices, and the Nuclear and Industrial Safety Agency has also issued a warning.

TEPCO officials and workers admit that internal contamination may have spread because all workers were not given clear instructions to wear face masks when working at the plant.

Another problem is that the emergency work station on the grounds of the Fukushima plant was damaged by hydrogen explosions at two reactors. That created **cracks that allowed radioactive materials to leak into the work station**, even though it is designed to prevent such leakage.

Because workers believed that radiation would not leak into the work station, they removed face masks when in the station, leading to the internal contamination.

Moreover, the whole body counters at the Fukushima plant used to measure internal contamination were exposed to radiation during the nuclear accident so there was no way of differentiating if measurements reflected contamination of workers or contamination of the equipment.

Workers had to be measured for internal contamination using two whole body counters at a facility in Iwaki, Fukushima Prefecture, away from the nuclear plant.

Labor ministry officials are caught in a bind because even with the relaxed upper limit for radiation exposure at the Fukushima No. 1 plant there could emerge a situation in which TEPCO does not have enough workers.

The labor ministry may be asked to further relax the radiation exposure levels if the work at the Fukushima plant becomes prolonged.

The labor ministry has also asked the Ministry of Economy, Trade and Industry, which oversees TEPCO, to compile a new structure to foster individuals capable of working at nuclear plants.

Rest area for workers at Fukushima plant

Gov't calls TEPCO radiation exposure standards 'overly optimistic'

As the number of workers exposed to high levels of radiation at the crippled Fukushima No. 1 Nuclear Power Plant increases, **the government is accusing plant operator Tokyo Electric Power Co. (TEPCO) of slack radiation dose calculations.**

"From the start, the way TEPCO calculates internal radiation exposure has been **overly optimistic**," a senior Ministry of Health, Labor and Welfare official stated.

On June 14, Health, Labor and Welfare Minister Ritsuo Hosokawa directed TEPCO to withdraw any worker exposed to more than 100 millisieverts of internal radiation at the disaster-stricken plant, sparking a dispute between the company and the government over radiation dose calculation standards, and delaying the implementation of worker safety-first policies at the plant.

Meanwhile, with work at the Fukushima plant -- where three reactors have melted down -- projected to go on for some time, uncertainty over exactly how high a dose workers there are subjected to may impact TEPCO's public timetable for resolving the nuclear crisis.

On May 30, TEPCO revealed that two of its Fukushima No. 1 plant workers had been exposed to a higher radiation dose than the 250 millisievert emergency upper limit, though the firm did not state how much of that exposure had been from radioactive materials taken into the body.

The labor ministry had demanded that TEPCO calculate workers' cumulative radiation exposure starting from March 12, when a hydrogen explosion destroyed the plant's No. 1 reactor building. However, TEPCO rejected the government demand, stating, "It's impossible to say when any internal radiation exposure occurred. If workers were on the job until the end of March, then cumulative radiation calculations should be made starting March 21, about half way between the day of the earthquake and the end of the month."

Internal radiation doses are measured with a device called a "whole body counter," which measures not only current exposure but sums up a person's total dose over time. As such, **TEPCO's insistence on calculating total radiation doses starting from March 21** has resulted in significantly lower exposure figures than those the government is using.

"We tried to persuade TEPCO to use a rigorous calculation method but the company wouldn't give in. In fact we're still at odds over the issue," the labor ministry's standards bureau told the Mainichi.

However, TEPCO's exposure estimates are only "provisional," and the utility leaves precise calculations to a radiology research laboratory that uses the government's dosage calculation standard. According to the lab, the two workers revealed on May 30 were exposed to 540-590 millisieverts of radiation internally, and 643-678 millisieverts in total.

TEPCO accepted the lab's conclusion, and submitted a revised report of worker radiation exposure totals on June 13. In that report, six more workers were revealed to have exceeded the emergency maximum exposure limit.

However, while the utility may have accepted the lab's, and thereby the government's, dosage standards, **Hosokawa's 100 millisievert internal exposure limit has little scientific foundation and was a purely political decision.**

Just after the revelation of the first two cases of workers exposed to radiation doses higher than the emergency limit, the labor ministry directed TEPCO to take internal radiation exposure measurements of the some 130 workers doing similar jobs. The results, reported on June 3, showed none of the 130 tested had exceeded the emergency upper limit, but there were three people who almost certainly had internal doses over 100 millisieverts. The ministry directed TEPCO to pull the three from the Fukushima plant.

The ministry furthermore stated that TEPCO's revised radiation dose calculations from June 13 "closely reflected actual conditions." In addition to the six workers who exceeded the maximum allowable exposure level revealed by the new figures, six more workers were shown to have doses over 200 millisieverts. Just to be on the safe side, labor ministry administrators also directed these six to be withdrawn from operations at the plant.

However Hosokawa, apparently fixated on his first June 3 directive ordering workers with internal doses exceeding 100 millisieverts be pulled from plant work, changed the administrative decision on the six workers. The change could be seen as a sign of worry that Hosokawa was pulling back set maximum dosage standards. However, a senior labor standards bureau official told the Mainichi it was "a political decision, based at least in part on TEPCO's tendency to be slow to take action."

Meanwhile, **an attorney for former nuclear plant workers suing TEPCO has called Hosokawa's 100 millisievert internal radiation exposure limit "too high."**

"That there hasn't been an internal radiation exposure limit before is also a major problem," said attorney Atsushi Suzuki, adding, "There are cases of multiple myeloma (a cancer of plasma cells, a type of white blood cell) from exposure to 70 millisieverts of annual external radiation, and cases of leukemia caused by just 5 millisieverts. The internal radiation doses Fukushima plant workers have been exposed to just leave me at a loss for words."

TEPCO unveils plan to construct shelters to cover radiation-leaking buildings

A miniature showing the planned construction of a shelter around disaster-hit Fukushima No. 1 Nuclear Power Plant's No. 1 nuclear reactor building. (Photo courtesy of Tokyo Electric Power Co.)

Tokyo Electric Power Co. (TEPCO), the operator of the troubled Fukushima No. 1 Nuclear Power Plant, unveiled on June 14 the outline of its plan to construct shelters to cover its radiation-leaking nuclear reactor buildings.

The shelters, each measuring approximately 47 meters wide, 42 meters long and 54 meters tall, consist of iron frames and vinyl chloride-coated polyester resin walls. The utility is planning to start putting up shelters on June 27 around its No. 1, 3 and 4 reactor buildings that were severely damaged in hydrogen explosions following the March 11 Great East Japan Earthquake and tsunami.

The structure is expected to contain the radioactive materials and toxic water vapor leaking from nuclear reactors and spent-fuel pools, while preventing rainwater from pouring into the buildings to be contaminated with radiation. The company said it is in the process of examining the shelter's quake and wind pressure resistance.

TEPCO first introduced its plan to construct shelters around the crippled nuclear reactors in April, when it announced a timetable for bringing an end to the ongoing nuclear crisis. In order to avoid radiation exposure of construction workers, building materials will be assembled into several large parts, each measuring tens of meters in diameter, at a TEPCO facility in the Fukushima Prefecture city of Iwaki, before they are transported by ferry to the nuclear power station and put together around the three reactor buildings using construction cranes.

On June 14, TEPCO also reported the results of a test using cesium-absorbing equipment developed by U.S. nuclear waste management firm Kurion Inc. The utility said it successfully reduced the amount of cesium 134 and 137 in the tainted water to around 1/3,000 of the levels before the decontamination treatment.

"The equipment has achieved the result we had expected," said a TEPCO official.

The company also plans to conduct a trial operation of another water treatment method developed by French nuclear engineering giant Areva SA, which removes radioactive materials from contaminated water using chemicals, with a full-fledged operation of the entire water treatment system scheduled to start on June 17.

(Mainichi Japan) June 15, 2011

U.S.: spent fuel pool never went dry in Japan quake

This Saturday May 7, 2011 image from video footage released on Sunday May 8, 2011 by Tokyo Electric Power Co., shows spent fuel storage pool of the Unit 4 reactor building at the crippled Fukushima Dai-ichi nuclear power plant in Okuma town, Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

WASHINGTON (AP) -- Water used to cool radioactive waste at the stricken nuclear complex in Japan did not dry up, as earlier feared, U.S. regulators said Wednesday in a reversal of a claim that pitted U.S. officials against Japan in the days after that country's nuclear disaster.

U.S. officials, most notably Nuclear Regulatory Chairman **Gregory Jaczko**, had warned that all the water was gone from one of the spent fuel pools at Japan's troubled nuclear plant, which would have raised the possibility of widespread nuclear fallout. Loss of cooling water in the reactor core could have exposed highly radioactive spent fuel rods, increasing the threat of a complete fuel meltdown and a catastrophic release of radiation.

Japanese officials had denied the pool was dry and reported that the plant's condition was stable.

On Wednesday, U.S. officials said newly obtained video shows that the spent fuel pool at Unit 4 at the Fukushima Dai-ichi complex probably did not go dry, as Jaczko had insisted in March.

Bill Borchardt, the NRC's executive director for operations, said U.S. officials welcomed the video evidence as "good news" and **one indication that the meltdown at the Fukushima plant's Unit 4 reactor "may not have been as serious as was believed."**

U.S. officials never have fully explained why Jaczko made the claim but said it was based on information from NRC staff and other experts who went to Japan after the March 11 earthquake and tsunami.

The pool for spent fuel at the No. 4 reactor of TEPCO's Fukushima No. 1 nuclear power plant is pictured in this Feb. 1, 2005, file photo.(Mainichi)

Jaczko did not mention the spent fuel pool during a commission meeting Wednesday at NRC headquarters in suburban Washington. He would not comment afterward.

Jaczko, 40, has been under fire in recent days, as the NRC's inspector general released a report indicating that he repeatedly misled fellow commissioners about his efforts to stop work on a disputed dump for high-level radioactive waste. Inspector General Hubert T. Bell said Jaczko manipulated the panel's four other commissioners by selectively withholding information on a crucial safety review of

the proposed Yucca Mountain nuclear waste dump in Nevada. Jaczko's actions allowed him to shut down the review last year without a vote of the full commission.

Bell told the House of Representatives' Energy and Commerce Committee that Jaczko's conduct was not criminal but added, "It's not an upfront way to do business."

Several agency scientists and a former NRC chairman also have questioned Jaczko's actions, and at least two Republican lawmakers have demanded that he resign.

A spokesman for the NRC said Wednesday that the belief that the spent fuel pool may have gone dry played a role in Jaczko's controversial decision to recommend that U.S. citizens stay at least 50 miles (80 kilometers) away from the crippled Japanese plant. The Japanese authorities had ordered evacuations of people within about 12 miles (19 kilometers) of the plant.

NRC spokesman Scott Burnell said Jaczko and other U.S. officials made the recommendation based on the best information available at the time.

"The NRC felt and continues to feel that the 50-mile recommendation was appropriate," he said.

In this photo released by Tokyo Electric Power Co. (TEPCO), workers operate a modified Putzmeister 70Z, the world's largest concrete pump mounted on a truck, to pump contaminated water from the Unit 4 at the tsunami-damaged Fukushima Dai-ichi nuclear power plant in Okumamachi, Fukushima Prefecture, northeastern Japan, Tuesday, April 12, 2011. (AP Photo/Tokyo Electric Power Co.)

Meanwhile, Charles Miller, a senior NRC executive who is leading a 90-day safety review of U.S. nuclear plants, told commissioners that current safety rules do not adequately weigh the risk of a single event that could knock out power from the grid and from emergency generators, as the quake and tsunami did in Japan. **Safety experts until now have focused on the risk of losing electricity from the grid or from emergency sources, but not both.**

NRC officials have said they are studying whether the nation's 104 nuclear reactors can cope with such a "station blackout," which could go on for days.

Commissioner George Apostolakis questioned why current rules assume that electricity would be restored within four or eight hours. "Why do we still assume things that are now, in retrospect, unrealistic?" he asked.

Jaczko said the Japan disaster had caused everyone involved in nuclear power, from industry to regulators, to rethink their assumptions.

"I think deep-down there was a belief that you would never see an event like this, that just simply we had done everything to basically take this type of event completely off the table. And obviously, we haven't," Jaczko said.

A final report from the task force is due in mid-July.

(Mainichi Japan) June 16, 2011

Panel to urge Fukushima Pref. to stop relying on nuclear power plants

FUKUSHIMA (Kyodo) -- An advisory panel set up by the Fukushima prefectural government plans to propose that the prefecture should seek to create a "safe, secure and sustainable" society without relying on nuclear power plants following the March 11 earthquake and tsunami, a draft plan showed Wednesday.

The proposal was included in a set of basic ideas compiled by the 12-member panel at its fifth meeting to provide the basis for deliberations on how to rebuild the disaster-ravaged prefecture in the northeastern Japan region of Tohoku.

With the central government continuing to retain nuclear power as a pillar of its energy policy, the panel's proposal could influence Japan's overall energy policy and other municipalities hosting nuclear power plants or related facilities.

The prefectural government set up the panel on May 13 to seek advice on reconstruction following the nuclear crisis at Tokyo Electric Power Co.'s Fukushima Daiichi power plant in the prefecture, which has been crippled since the disaster.

The panel consists of university professors and other advisers, including corporate executives, and is chaired by Hiroshi Suzuki, a professor emeritus at Fukushima University.

In its proposals, the panel envisions the prefecture drastically increasing the use of renewable energy for power generation and promoting energy-saving and recycling measures while ending its reliance on nuclear power plants.

Before the disaster, a total of 10 nuclear reactors were in operation at Tokyo Electric's Fukushima Daiichi and Daini power plants in the prefecture.

The panel also proposed that each area in Fukushima become energy-independent through a mix of various energy sources and that the prefecture host many businesses related to renewable energy to achieve environmental protection and economic revitalization at the same time.

In addition, the prefecture should introduce a variety of necessary measures related to transportation, information and telecommunications, and other infrastructure to cope with emergency situations so as to create a society where all residents can live in safety and peace, the panel said.

The panel is scheduled to compile a final set of recommendations as early as the end of July. Based on the final recommendations, the prefectural government expects to compile specific plans for post-disaster reconstruction work by the end of this year.

(Mainichi Japan) June 16, 2011

TEPCO continues efforts to fully operate key water treatment system

In this June 9, 2011 photo released Saturday, June 11, 2011 by Tokyo Electric Power Co. (TEPCO), equipment inside the cesium absorption tower, part of the newly-built radioactive water processing facilities at Fukushima No. 1 nuclear power plant in Okuma, Fukushima prefecture, is shown. (AP Photo/Tokyo Electric Power Co.)

TOKYO (Kyodo) -- Tokyo Electric Power Co. continued its efforts Wednesday to fully operate a newly installed radioactive water treatment system at its Fukushima Daiichi nuclear power plant crippled by the devastating March 11 earthquake and ensuing tsunami.

The utility known as TEPCO also worked on beginning to test whether two key components of the system that can decontaminate water including radioactive materials can work well simultaneously, following a trial run of each, ahead of its full-scale operation it plans to start Friday.

It is believed that optimal operation of the system, which is designed to remove highly radioactive materials from a massive amount of water accumulating at plant facilities, will help to contain the

three-month-old nuclear crisis as the utility plans to eventually recycle the tainted water to cool the plant's damaged reactors.

Earlier in the day, TEPCO checked a decontamination installation developed by France's Areva SA, one of the two key components of the system, which removes radioactive cesium and strontium by concentrating them with a chemical agent and depositing them as sediment.

The utility tested the other component, an installation to absorb cesium developed by Kurion Inc. of the United States, on Tuesday. In the test, TEPCO successfully reduced cesium in low-level contaminated water to the level it had expected, the government's nuclear safety agency said.

In this May 10, 2011 file photo released by Tokyo Electric Power Co., workers check the status of the water level indicator at the Unit 1 reactor building at the Fukushima Dai-ichi nuclear power plant in Okuma town, Fukushima Prefecture, northeastern Japan.(AP Photo/Tokyo Electric Power Co., File)

The plant operator said it hopes to process around 1,200 tons of highly radioactive water per day.

The contaminated water accumulating at reactor facilities, including coolant liquid leaking from damaged reactors, has been diverted to other parts of the plant to prevent it from overflowing at the facilities, but those locations are nearing full capacity.

TEPCO had planned to begin a trial run of the treatment facility last Friday but was forced to postpone it after water was found leaking from a pipe, hampering the company's initial plan to fully operate the new system from Wednesday.

Regarding other progress, the utility said it started to transfer water in the No. 1 reactor's condenser to a tank earlier in the day to use it as a new place to store contaminated water.

The condenser could store 1,600 tons of such water if it becomes empty, TEPCO said.

The utility also said it will set up a water circulation system for the pool storing spent nuclear fuel in the No. 3 reactor building by the end of this month, aiming to cool it stably.

In this May 27, 2011 photo released on June 2, 2011 by Tokyo Electric Power Co. (TEPCO), temporary storage tanks for low-level radioactive polluted waters used for temporary cooling system in Fukushima Dai-ichi nuclear power plant in Okuma, Fukushima prefecture, northeastern Japan, are shown. (AP Photo/Tokyo Electric Power Co.)

The Nuclear and Industrial Safety Agency, meanwhile, said TEPCO employees early Wednesday found a worker at the power plant smoking outside without wearing a mask, despite growing concern about the health of workers at the site.

The agency said it has called on the plant operator to implement thorough measures to prevent workers at the power station from being excessively exposed to radiation.

(Mainichi Japan) June 15, 2011

Fukushima No. 1 plant worker irradiated after taking off mask for smoke

A worker at the crippled Fukushima No. 1 Nuclear Power Plant absorbed a radiation dose of 0.24 millisieverts after taking his mask off to have a smoke, plant operator Tokyo Electric Power Co. (TEPCO) announced on June 15.

According to TEPCO, the worker in his 50s was helping put together a crane on the morning of June 15 as part of preparations to build an enclosure around the plant's No. 1 reactor. He was spotted by a site manager smoking in the cabin of another crane at about 11 a.m.

The man was later tested for internal radiation exposure with a "whole body counter" in nearby Iwaki, Fukushima Prefecture, and registered a 0.24 millisievert dose -- not a serious exposure. The man had been working at the plant since March 23.

Currently, smoking, eating and drinking are forbidden on the plant grounds except in designated break rooms.

"We have informed workers of the dangers of internal radiation exposure, so this incident is unfortunate," a TEPCO representative stated. "We will take thorough measures to prevent a recurrence."

(Mainichi Japan) June 16, 2011

TEPCO starts up water treatment system, but massive radioactive waste feared

Tokyo Electric Power Co. (TEPCO) began a trial run of a radioactive water treatment system at the crippled Fukushima No. 1 Nuclear Power Plant on June 15 in a desperate effort to break away from the vicious cycle of injecting water into reactors to cool them and ending up with more contaminated water.

But **even if the system, developed by France's Areva SA, were to operate smoothly, it would produce a massive amount of high-level radioactive waste** that could affect TEPCO's roadmap to bring the troubled nuclear reactors under control by early next year.

"The water treatment system is moving along as scheduled, although contaminated water leaked from a pipe," Hidehiko Nishiyama, spokesman for the Nuclear and Industrial Safety Agency, told a news conference on June 15.

TEPCO, the operator of the troubled Fukushima No. 1 Nuclear Power Plant, will try to reach "Step 1" of the roadmap, in which radiation emissions are steadily declining, by mid-July. It hopes to reach "Step 2," in which leakages of radiation are controlled and amounts of radiation are drastically reduced, within three to six months.

But **while contaminated water is treated, the system developed by Areva is expected to produce about 2,000 cubic meters of radioactive sludge by the end of this year.** The sludge is likely to be highly radioactive with 100 million becquerels per cubic centimeter. **In addition, about two to four 2.3-meter-tall cesium-absorbing containers are expected to be needed each day, but the roadmap does not take into account work to dispose of the containers.**

"Massive amounts of extremely high levels of radioactive waste will be produced and our work to deal with the crisis at the No. 1 Nuclear Plant will enter **unknown territory**. It could affect the roadmap," said a senior official of the Ministry of Economy, Trade and Industry. The ministry and the Nuclear and Industrial Safety Agency are considering measures, including revising laws or enacting new laws, to deal with massive amounts of radioactive waste.

In the roadmap revised in May, TEPCO included the operation of circulatory cooling systems using water that had had radioactive substances removed.

At the No. 2 reactor, a hydrogen explosion damaged the pressure suppression pool. According to analysis by the Nuclear and Industrial Safety Agency, there is a hole of about 300 square meters there. Therefore, in order to circulate cooling water through the reactor, either damaged parts would need to be repaired or the pool would need to be covered with something like a huge concrete structure. But it is difficult for workers to approach the reactor because radiation levels in the reactor building are so high. As a result, TEPCO has not even been able to confirm damaged spots.

The situation is the same at the No. 1 and 3 reactors. The buildings housing the two reactors sustained serious damage in the hydrogen explosions that hit them. Massive repair work could therefore be required to ensure that water circulates through the cooling systems. It is not clear when

the circulatory cooling systems will be made operational, and therefore contaminated water will be kept in a temporary tank after being treated.

Be that as it may, **the radioactive water treatment system will have to be kept running all the time as long as work to cool nuclear fuel continues.** It will cost a fortune to treat the radioactive water and manage radioactive waste.

In this May 27, 2011 photo released on June 2, 2011 by Tokyo Electric Power Co. (TEPCO), temporary storage tanks for low-level radioactive polluted waters used for temporary cooling system in Fukushima Dai-ichi nuclear power plant in Okuma, Fukushima prefecture, northeastern Japan, are shown. (AP Photo/Tokyo Electric Power Co.)

"This work has not been carried out anywhere else in the world. While keeping the worst-case-scenarios in mind, they should quickly work out measures to treat contaminated water," said Teruyuki Honda, professor of nuclear environmental engineering at Tokyo City University.

(Mainichi Japan) June 16, 2011

Gov't to designate new evacuation spots near Fukushima plant

TOKYO, June 16, Kyodo

Japan has decided to designate new spots for possible evacuation near the crisis-hit Fukushima Daiichi nuclear power plant that are feared to have radiation levels which go beyond an internationally recommended benchmark, the top government spokesman said Thursday.

The policy on the areas dubbed as "hot spots" will cover specific households in a residential area, Chief Cabinet Secretary Yukio Edano said at a news conference. Currently, the government in principle imposes an evacuation order on a municipality basis.

He said that while individuals can choose to evacuate or not, children and pregnant women especially are urged to leave the hot spots, which register **radiation levels that could exceed the 20-millisieverts yardstick a year.**

Govt sets policy to handle radiation sludge (NHK online)

The government has announced guidelines on how to dispose of sludge that contains radioactive material.

Radioactive material has been detected in sludge from waste water treatment plants in many areas, mainly in eastern Japan, since the crisis began at the Fukushima Daiichi nuclear power plant.

The guidelines released by the government's nuclear disaster taskforce on Thursday say **disposal facilities with filters will be used to prevent radiation leaks from fumes that are created when sludge is burned (?????) or dissolved.**

They say **sludge containing radiation of more than 100,000 becquerels per kilogram will be stored at facilities tightly shielded by substances like concrete.**

But the taskforce will continue discussions to determine how to ultimately dispose of it.

The guidelines say **sludge measuring over 8,000 to 100,000 becquerels of radiation can be buried in waste disposal sites,** after steps are taken to limit nearby residents' annual exposure to 10 microsieverts or lower.

They also say **sludge bearing readings of 8,000 becquerels or less can be buried after thorough waterproofing measures have been taken, as long as disposal sites are not used for housing purposes.**[Faudra pas oublier de mettre une pancarte à la surface ...]

The government has informed 13 relevant prefectures of the decision.

Thursday, June 16, 2011 18:09 +0900 (JST)

Gov't allows part of radioactive tainted sludge to be buried

In this Monday, June 13, 2011 photo released by Tokyo Electric Power Co., a machine collects radioactive substances in the air for sampling at the Unit 3 of the crippled Fukushima Dai-ichi nuclear power plant in Okuma, Fukushima prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

TOKYO (Kyodo) -- A government task force on nuclear emergency said Thursday it has decided to allow sludge containing 8,000 becquerels per kilogram or less of radioactive cesium to be buried in waste disposal sites only if residential houses are not built there in the future.

It also said sludge containing over 8,000 to 100,000 becquerels per kg of cesium could be buried after evaluating its safety individually, while sludge measuring more than 100,000 becquerels per kg should be kept under shielding but its final disposal manner is undecided.

The announcement came as radioactive materials have been detected in water and wastewater treatment plants in many regions including Tokyo since the Fukushima Daiichi nuclear power plant was crippled by the March 11 earthquake and tsunami.

Goshi Hosono, a special adviser to Prime Minister Naoto Kan in charge of the nuclear crisis, said at a press conference that the state government is considering bearing the disposal costs.

The task force said the decision targets 13 prefectures, including Fukushima, Tokyo and Shizuoka.

(Mainichi Japan) June 17, 2011

Full-scale operation of key water treatment system may be delayed

TOKYO (Kyodo) -- The operator of the crippled Fukushima Daiichi nuclear power plant said Thursday that water was found leaking from a newly installed radioactive water treatment system during its trial run, hampering the firm's plan to fully operate it from Friday.

Optimal operation of the treatment system, which is designed to remove highly radioactive materials from a massive amount of water accumulating at the power station, is considered essential to containing the nuclear crisis as Tokyo Electric Power Co. plans to eventually recycle the water to cool the plant's damaged reactors.

But the utility, known as TEPCO, **will be forced to deal with the water leakage problem first**, raising the possibility that full operation of the key facility to clean up contaminated water may be postponed until Saturday.

The treatment system is composed of installations developed by Kurion Inc. of the United States and France's Areva SA that remove radioactive materials such as cesium from contaminated water, as well as devices to eliminate oil and salt.

The utility said it has tested each component for the past few days and **the installations of the two companies in combination were capable of reducing cesium in contaminated water to around a 100,000th of its original level**. It hopes to process around 1,200 tons of highly radioactive water per day.

The contaminated water accumulating at reactor facilities, including coolant liquid leaking from reactors damaged by the March 11 earthquake and tsunami, has been diverted to other parts of the plant to prevent it from overflowing at the facilities, but those locations are nearing full capacity.

Goshi Hosono, a special adviser to Prime Minister Naoto Kan, said at a press conference Thursday that **the utility will release Friday an updated version of its road map**, unveiled in April, for containing the three-month-old nuclear crisis.

But Hosono, also a lawmaker of the ruling Democratic Party of Japan tasked with handling the nuclear crisis, did not make any comment on whether the plant operator will change its broad time frame for stabilizing the troubled reactors by around January.

Meanwhile, TEPCO said Thursday it plans to open the doors of the No. 2 reactor building to reduce internal humidity, with the aim of improving the working environment.

The utility said it will open the doors after it gains approval from the Nuclear and Industrial Safety Agency and will go ahead with preparations for cooling the reactor by taking steps such as adjusting its pressure and water-level gauges as well as setting up pipes to inject nitrogen into the vessel to avoid a hydrogen explosion.

As TEPCO began operating ventilation equipment at the building last Saturday, the amount of radioactive materials that could be released to the outside atmosphere after the doors open would not reach a level that affects the environment, company officials said.

The radiation level in the No. 2 reactor building has been declining but humidity has reached as high as 99.9 percent.

(Mainichi Japan) June 17, 2011

NHK online _Tepco a identifié l'origine de la fuite dans l'appareil de décontamination de l'eau radioactive

La Compagnie d'électricité de Tokyo, Tepco, a découvert l'origine de la fuite détectée dans le système mis en place pour réduire la contamination de l'eau hautement radioactive accumulée dans les locaux de la centrale Fukushima Dai-ichi.

Jeudi, les derniers essais du système ont dû être suspendus après la découverte d'une fuite d'eau au niveau d'un appareil américain conçu pour retirer le césium. Cet appareil est un élément essentiel du système.

D'après Tepco, l'origine de cette fuite se situe au niveau d'une soupape de ventilation fixée à un des conteneurs incluant l'appareil. Les techniciens ont également découvert qu'une soupape d'évacuation d'eau installée sur un autre conteneur était fermée. Cela signifie, estime Tepco, que la fuite a bien eu lieu au niveau de la soupape de ventilation. Cette soupape est en cours de remplacement.

Fukushima city gov't begins monitoring radiation levels in detail

TOKYO (Kyodo) -- The Fukushima city government began **monitoring radiation levels at various locations across the city Friday**, a day after the central government decided to designate new spots near the crisis-hit Fukushima Daiichi nuclear power plant for possible evacuation.

Some areas of Fukushima Prefecture's capital city, which currently does not fall within any of the government-designated evacuation zones, are expected to be designated as "hot spots" as their radiation levels are sporadically higher than those in nearby areas.

The municipal government will monitor radiation levels **over two days at a total of 1,045 places, such as parks, meeting places, street gutters and along school routes**, as requested by neighborhood groups, city officials said.

It will mobilize 31 portable dosimeters to monitor radiation levels at each location at heights of 1 centimeter, 50 cm and 1 meter above ground level five times each at intervals of 10 seconds.

Monitoring results will be made known to residents through the neighborhood groups and also published on the city government's website.

The city government will listen to experts on the results and will again monitor radiation levels at places where high levels of radiation were detected.

It also plans to procure about 100 more portable dosimeters to rent to residents by the end of July.

On Thursday in Tokyo, Chief Cabinet Secretary Yukio Edano said the central government has decided to designate new spots for possible evacuation near the Fukushima Daiichi nuclear power plant. These are spots feared to have radiation levels that exceed an internationally recommended upper limit for an emergency.

The government will support those who wish to evacuate from the hot spots, which register radiation levels that could exceed the 20-millisieverts yardstick per year, according to Edano. Children and pregnant women especially are urged to leave.

The municipal governments of Date and Minamisoma, also in Fukushima Prefecture, have already launched their own monitoring of radiation levels throughout their respective cities, as some hot spots have been found.

(Mainichi Japan) June 17, 2011

News navigator: What are radiation 'hot spots'?

In this photo from a footage of a live camera released by Tokyo Electric Power Co. (TEPCO), black smoke billows from the crippled Fukushima No. 1 Nuclear Power Plant in Okumamachi, northeastern Japan, on March 22, 2011. (AP Photo)

The Mainichi answers common questions readers may have about radiation "hot spots."

Question: The term "hot spot" has been appearing in the news lately with regards to radiation, but what does it mean?

Answer: The term refers to areas where radiation levels are comparatively higher than the areas around them, regardless of distance from the crippled Fukushima No. 1 Nuclear Power Plant. The village of Iitate, Fukushima, where residents were asked to evacuate after it was predicted radiation exposure levels could reach 20 millisieverts a year, is one such "hot spot." Similar concentrations of radiation have also been measured at other, smaller hot spots. Residents have expressed anxiety over these comparatively high measurements.

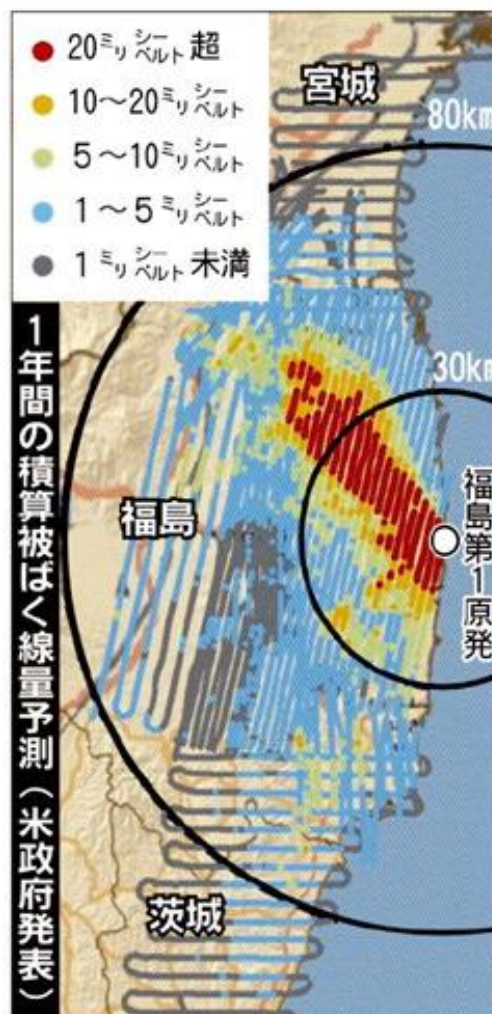

Q: Why do areas far from the plant become hot spots?

A: **Radioactive materials emitted from a damaged nuclear plant do not spread evenly.** Rather, they form into plumes that are carried by the wind. In the Fukushima disaster, large-scale emissions of radioactive materials are thought to have occurred from March 15 to 16 after hydrogen explosions damaged reactor buildings at the plant.

According to an analysis by the Japan Atomic Energy Agency, a plume of radioactive materials started heading west around noon on March 15, and from around 2 to 3 p.m. it came into contact with rain and fell over the cities of **Koriyama and Shirakawa**. Later, the plume was carried northwest and rained **over areas including Iitate** from the evening of March 15 to the predawn hours of March 16.

In areas over which plumes happened to come into contact with rain, radioactive materials were deposited on the ground, creating hot spots.

Q: I've heard that hot spots have been found in the Tokyo metropolitan area as well. Is that true?

The NNSA hazard map released by the U.S. federal government. The Fukushima No. 1 Nuclear Power Plant is marked by a white dot at right.

A: When the governments of Tokyo and Chiba Prefecture began taking measurements, they found a few areas where radiation levels were higher than the surroundings. The highest measurements were around 0.5 microsieverts per hour. A microsievert is 1/1000 of a millisievert. At this level, even if a person were outside at the hot spot eight hours a day for a year, they would only be exposed to 1.4 millisieverts -- less than a tenth of the exposure predicted for areas asked to evacuate in Fukushima Prefecture.

Q: Does that mean the Tokyo area is safe?

A: Many experts seem to think so. However, **it is best not to be exposed to any more radiation than is necessary** [ah !], which is why the International Commission on Radiological Protection recommends that radiation exposure be limited as much as is rationally possible.

Hiromi Yamazawa, a Nagoya University professor and expert in radiation's effects on the environment, says, "As to whether measures need to be taken to lower radiation levels in the Tokyo area, science alone cannot answer that question. It should be decided through discussion between local residents and anyone else who stands to be affected in one way or another." (Answers by Taku Nishikawa, Science & Environment News Department)

(Mainichi Japan) June 17, 2011

Damage found to 43 pipes in steam condenser at Hamaoka atomic plant (Kyodonews)

TEPCO starts full operation of key water treatment system

TOKYO, June 17, Kyodo

Tokyo Electric Power Co. moved closer to realizing the stable cooling of the troubled reactors at the Fukushima Daiichi power plant on Friday as a key system to clean highly radioactive water accumulating at the plant started full-scale operation.

Issuing an updated version of a road map for bringing Japan's worst nuclear accident under control, Tokyo Electric expressed its confidence in achieving stable cooling of all the spent nuclear fuel pools in one month, and made no revision to its plan to bring the reactors into "cold shutdown" by around January at the latest.

With the nuclear crisis continuing for more than three months, the plant operator known as TEPCO highlighted the need to enhance radiation exposure management of workers engaged in restoration efforts after recent findings showed some of them had far exceeded their radiation dose limit.

Panel to discuss radioactive sludge disposal

Japan's land ministry has set up an expert panel to examine ways to deal with radioactive sludge.

The panel held its first meeting on Friday, one day after the government announced guidelines on the handling of sludge according to its radiation levels.

Radioactive substances have been detected in sludge at wastewater treatment facilities in at least 16 prefectures, mainly in eastern Japan, since the accident at the Fukushima Daiichi nuclear plant.

The panel will study ways to measure radiation levels at wastewater plants, standardize methods of storing sludge, and ensure nearby residents are informed.

The panel aims to conclude discussions as early as August and inform local authorities of its findings.

Friday, June 17, 2011 17:51 +0900 (JST)

Local govts skeptical about sludge guidelines

NHK has found that local authorities are skeptical about government guidelines on the handling of radioactive sludge.

NHK surveyed 30 local authorities after the government announced the guidelines on Thursday. The procedures suggest how to deal with radioactive sludge that has been found in wastewater treatment plants following the crisis at the Fukushima Daiichi nuclear power plant.

The 30 respondents have either been informed of the guidelines or have checked the sludge at their treatment facilities for possible contamination.

The guidelines permit sludge with radiation levels of up to 8,000 becquerels per kilogram to be buried after waterproofing steps are taken. Even under these conditions, eight of the respondents said they cannot locate appropriate disposal sites.

Three others said they are not sure whether they can ease their residents' concerns.

Twelve said the government should provide detailed instructions on how to dispose of the sludge rather than leaving it up to them. Some said the task is too large to handle at the regional level.

Seventeen of the respondents urged the government to offer concrete methods of disposal, find appropriate disposal sites, or shoulder the costs of the operations.

Commentaire sur le problème de l'eau contaminée

Dans notre commentaire d'aujourd'hui, nous avons interviewé Akio Koyama, professeur à l'institut de recherche sur les réacteurs nucléaires, qui dépend de l'université de Kyoto. Nous avons évoqué avec lui le traitement de l'eau hautement radioactive, qui est considéré comme une étape essentielle à la résolution des problèmes à la centrale de Fukushima.

Akio Koyama :

Tepco, la Compagnie d'électricité de Tokyo, ne pourra pas passer à l'étape suivante ou progresser selon le calendrier qu'elle s'est fixée sans avoir résolu ce problème. Il y a beaucoup de travail à fournir pour refroidir le carburant des réacteurs 1, 2 et 3 et les barres de combustible usagé. Les techniciens doivent entrer dans les bâtiments des réacteurs et des turbines. Mais la présence d'eau hautement radioactive freine leurs travaux.

La quantité d'eau contaminée augmente tous les jours, au fur et à mesure de refroidissement des réacteurs. Le pire des scénarios serait que cette eau se déverse dans l'océan. Son traitement est donc des plus urgent.

Radio Japon :

Que faudra-t-il faire une fois que le traitement aura commencé ?

Akio Koyama :

Le plus important sera la gestion des substances radioactives retirées de l'eau. Le système utilisé cette fois fonctionne en utilisant de la zéolite, un minéral qui absorbe du césium, et différents agents chimiques pour isoler les autres substances radioactives. Cela signifie qu'il restera d'importantes quantités d'absorbants et de dépôts très contaminés. Quand les 100 000 tonnes d'eau radioactive seront traitées, les résidus représenteront 2 à 3 pour cent de ce volume. Cela signifie qu'il restera 2 à 3000 tonnes de déchets très contaminés.

Le pire est que le niveau de radioactivité de ces déchets est 100 à 1000 fois supérieur à celui de l'eau contaminée. Or, pour l'instant, il n'y a aucun projet de traitement de ces déchets. S'en occuper représentera une tâche importante.

RJ :

C'était Akio Koyama, professeur à l'institut de recherche sur les réacteurs nucléaires, qui dépend de l'université de Kyoto.

Tepco Suspends Water Treatment Operation

By [DAISUKE WAKABAYASHI](#)

<http://online.wsj.com/article/SB10001424052702303823104576392720295079568.html>

TOKYO—[Tokyo Electric Power](#) Co., the operator of the damaged Fukushima Daiichi nuclear power plant, said **it halted the use of a new system for decontaminating highly radioactive water after levels of radiation in one part of the system rose faster than expected.**

The suspension came only five hours after Tepco started operation of the system, which aims to reduce the vast amounts of irradiated water at the facility. The pools of highly radioactive water are a major obstacle to stabilizing the stricken power plant.

The latest hiccup reflects the ongoing struggle to get the reactors stabilized even as Tepco stands by its target of achieving a "cold shutdown" of the three most damaged reactors by mid-January 2012.

Tepco started operation of the new system, which incorporates U.S. and French technology, at 8 p.m. local time Friday, and then halted its use at 12:54 a.m. local time Saturday.

A Tepco spokesman said it is still unclear when it will restart the decontamination system.

The problem stemmed from the levels of radiation in a machine designed to absorb cesium. **The radiation levels had reached a stage requiring a change of the filtering cartridges.**

Tepco said it found that one of the cartridges was clogged with radioactive sludge and it is now trying to flush down the clogs in order to resume normal operations.

Separately, Japan's Ministry of Economy, Trade and Industry said it has verified the implementation of additional safety steps at nuclear power plants in Japan. **More than 30 of Japan's 54 commercial reactors are not in operation because checkups on the plants had not been completed following the March 11 disasters.**

The government also implemented additional safety measures in the case of damage to the reactor cores such as steps to prevent hydrogen explosions from happening inside the facilities. In order to resume operation at an idle reactor, local communities around the plants must now sign off on the resumption of service.

The ministry's announcement excludes the Fukushima Daiichi facility.

TEPCO likely to delay start of stable cooling of Fukushima reactors

TOKYO (Kyodo) -- Tokyo Electric Power Co. will likely put off Saturday's planned start of stable cooling of troubled reactors at the Fukushima Daiichi nuclear power plant, having suspended a key water treatment system less than five hours after beginning its full operation.

The newly installed system, which began full operation at 8 p.m. Friday, was halted at 12:54 a.m. Saturday as the radiation level of a component to absorb cesium had reached its limit and required replacement earlier than expected, the plant operator known as TEPCO said.

The system is seen as a key step to containing the three-month-old nuclear crisis as it would clean highly radioactive water hazardously accumulating at the plant premises and preventing restoration work.

The contaminated water is a side effect of the current emergency step of injecting coolant water from outside in place of the reactors' cooling functions lost in the March 11 earthquake and tsunami

(Mainichi Japan) June 18, 2011

Tepco suspend le système de décontamination de l'eau à la centrale Fukushima (NHK)

La Compagnie d'électricité de Tokyo, Tepco, a suspendu l'opération d'un système de décontamination d'eau hautement radioactive à la centrale nucléaire Fukushima Dai-ichi car l'une des parties avait atteint sa limite maximale d'exposition aux radiations en moins de 5 heures.

Le système avait été mis en service hier vendredi soir.

L'un des composants du système utilise de la zéolite, un minéral qui absorbe le césium radioactif. Une pièce du dispositif de fabrication américaine était censée durer un mois. Mais la radiation dépassant les 4 millisieverts par heure, limite maximale autorisée par le constructeur, a rendu la pièce inutilisable. C'est pourquoi il a fallu la remplacer plus tôt que prévu.

Tôt ce matin samedi, Tepco a suspendu l'opération utilisant le dispositif, pour tenter de découvrir la cause d'un tel phénomène.

"Jusqu'à présent, aucune anomalie dans le système ou fuite d'eau n'a été détectée" a déclaré l'entreprise.

TEPCO suspends water decontamination system (NHK online)

Tokyo Electric Power Company has halted operation of a system to decontaminate highly radioactive water at the Fukushima Daiichi nuclear plant as **one of the parts reached its radiation exposure limit in less than 5 hours.**

The system went into service on Friday night.

One component of the system uses the mineral zeolite to absorb radioactive cesium. A replacement part of the US-made device had been expected to last one month, but radiation exceeding the maximum 4 millisieverts per hour led to the dramatically shortened lifespan.

TEPCO suspended operation of the device early on Saturday to determine the cause.

The utility says it has so far found no abnormalities with the system or water leakage in the system. It

adds that the device's dosimeter may have detected radiation from nearby pipes containing contaminated water or other radioactive materials.

The treatment system holds the key to halting the accumulation of highly radioactive water and re-circulating contaminated water to cool the reactors.

Saturday, June 18, 2011 13:00 +0900 (JST)

Minister seeks reactor restart, says severe accident measures taken

TOKYO, June 18, Kyodo

Industry minister Banri Kaieda on Saturday called for the restart of nuclear reactors currently suspended, to meet summertime electricity demand, saying immediate countermeasures for severe accidents have been taken "appropriately" at the nation's nuclear power plants.

Noting that power shortages facing the country could cause a "hollowing out" of Japanese industries, he called on local governments and residents to accept the restart of reactors that have been halted longer than planned due to the ongoing nuclear crisis at the Fukushima Daiichi plant.

Kaieda expressed readiness to visit areas hosting nuclear power plants to gain the acceptance of local governments and residents for the move, telling a news conference, "The state will thoroughly explain the safety of atomic energy to local people as its responsibility."

Mountain of problems still remains before Fukushima plant brought under control

One cannot help but wonder how far efforts being made by the national government and Tokyo Electric Power Co. (TEPCO) to bring the Fukushima No. 1 Nuclear Power Plant under control have progressed.

Two months have passed since TEPCO first unveiled a roadmap for bringing the crippled plant under control, but various problems that have occurred since then show the roadmap was overly optimistic.

Uncertainty over the current state of the power plant and when it could be brought under control continues to disrupt the lives of locals. Many people probably wonder whether the wisdom and power of Japan and the rest of the world are effectively being brought together and applied in the ongoing efforts at the plant.

The government and TEPCO recently announced updated roadmaps on bringing the Fukushima plant under control and supporting people affected by it, and they talked about how far measures in the roadmaps have been implemented. However, they should also give a more general overview of the current situation of the nuclear power station and the outlook for stabilization of the plant, not just talk

about specific measures. It would also be good to give an updated assessment of the level of risk involving the plant.

At the Fukushima plant, of great concern now is how to treat radioactive water collected in the reactor and turbine buildings. The massive volume of the water, which is estimated to be at over 100,000 cubic meters, is obstructing work at the plant, and if removal of the contaminated water is delayed, it could leak into the ground around the structures or into the sea.

TEPCO has been setting up a system that includes parts from French and U.S. makers to decontaminate the radioactive water and return it to the reactors, which would allow cooling of the nuclear fuel without bringing in water from the outside, which could leak and increase the amount of trapped radioactive water. However, running of the system has been delayed after a water leak and other problems. Further delay-causing problems could occur if TEPCO does not first ferret out and correct their root causes.

Furthermore, although the water circulation system has started now, how long should it be run? It is also not clear what officials mean when they refer to stability of the plant, when we have not only a meltdown in the inner containment vessels, but the possibility of melted fuel having made its way to the outer containment vessels.

Dealing with the highly radioactive waste sludge that will be left after cleansing the radioactive water is another problem, and since Japan is encountering this and other issues with the nuclear disaster for the first time, work has had to start from the research and development phase. According to the roadmap, TEPCO will aim to store the radioactive sludge and will evaluate the construction of shielding walls to keep radioactive water from contaminating nearby groundwater and nearby sea in mid-July or later, but the utility and the government should take quicker action.

Measures to minimize nuclear plant workers' exposure to radiation and improve their medical care have been incorporated into the updated roadmap and are important steps needed to support workers at the plant for the years to come. Workers who had internal exposure to high levels of radiation were recently revealed, but it was months after their exposure. The government and TEPCO need to speed up full measurements of workers' exposures to radiation and efforts to minimize their exposure.

Another problem is that the evacuation of residents near the power plant is still confused. Although it is important to take care of residents near "hot spots" -- areas of relatively high levels of radiation including ones far from the plant -- the government also needs to give clear guidance to residents in areas that fall under designated evacuation zones while only having had low levels of radiation detected.

The central government and TEPCO may not have changed the time frames for their roadmaps, but the fact is that a massive number of issues remain to be addressed before the Fukushima No. 1 Nuclear Power Plant is brought under control.

(Mainichi Japan) June 18, 2011

TEPCO not to start stable Fukushima plant cooling till Mon.

TOKYO, June 18, Kyodo

Tokyo Electric Power Co. cannot begin work to cool the troubled reactors at the Fukushima Daiichi nuclear power plant **until Monday at the earliest**, the utility said Saturday, adding it is fixing a problem that forced it to suspend full operation of a new water decontamination system.

The system, which began full operation at 8 p.m. Friday, was halted at 12:54 a.m. Saturday as the radiation level of a component to absorb cesium had reached its limit and required replacement earlier than expected, the operator known as TEPCO said.

The operator earlier assumed it would have to replace the component once a month, it said.

TEPCO to vent air from Fukushima reactor building (Kyodonews dimanche)

TEPCO soon to open doors to No.2 reactor building

Tokyo Electric Power Company says it will **soon** begin to open the doors to the No. 2 reactor building at the Fukushima Daiichi nuclear plant for ventilation, to lower humidity, and to start restoration work.

Extremely high humidity of nearly 100 percent, due to moisture apparently from the containment vessel and spent-fuel storage pool, has been hampering work inside the building.

TEPCO has been operating an air purification device for more than a week to reduce the radioactive concentration inside the building. **The company now assesses that opening the doors will raise the level of background radiation around the plant by 0.0014 microsievert per hour, far below the permissible annual limit for ordinary people of one millisievert.**

Speaking to reporters on Sunday morning, a TEPCO official stressed that the planned door-opening will have little impact on the nearby environment.

The company plans to begin opening the doors at 8 PM on Sunday and to fully open them at 4 AM on Monday if no problems arise.

TEPCO says the initial stage of the planned restoration work will include staff surveying radiation levels and adjusting gauges inside the building.

Sunday, June 19, 2011 12:35 +0900 (JST)

Difficultés grandissantes pour la décontamination de l'eau hautement radioactive à Fukushima

La relance du système de décontamination de l'eau hautement radioactive accumulée dans les locaux de la centrale nucléaire de Fukushima pourrait prendre plusieurs jours.

La Compagnie d'électricité de Tokyo, Tepco, l'a mis en route vendredi soir. Elle a dû l'arrêter après cinq heures d'utilisation car le niveau de radiation d'un appareil d'absorption du césium avait augmenté plus vite que prévu. Cet appareil est conçu pour extraire le césium mais également le pétrole et le technétium.

Les techniciens de Tepco pensent qu'il a pu absorber une quantité supérieure aux attentes, de matières radioactives et de pétrole. Ils s'efforcent maintenant de trouver une solution au problème mais il faudra du temps.

En outre, l'évolution de la situation pourrait obliger la compagnie à revoir le fonctionnement de l'installation dans son ensemble et à mesurer les effets de la radioactivité émise des tuyaux passant à proximité de l'appareil incriminé.

Ces difficultés interviennent alors que l'eau hautement radioactive pourrait déborder dans une semaine si aucune mesure de prévention n'est mise en oeuvre.

TEPCO: cleanup system could take time

The operator of the crippled Fukushima Daiichi nuclear power plant says it may take several days before a system to decontaminate highly radioactive water accumulating in the facility can be restarted.

Tokyo Electric Power Company put the system into full operation on Friday night, but had to halt it 5 hours later as the radiation level of a cesium absorption device rose higher than expected.

The device is also designed to remove oil and technetium.

TEPCO says it may have absorbed larger-than-expected amounts of radioactive materials along with oil. The utility is now working on measures to solve the issue.

TEPCO says the effort will require time. In addition, depending on the situation, it may have to reconsider the working of the entire system and examine the effect of radioactivity emitted from nearby pipes.

There are concerns that the highly radioactive water may overflow in around one week if no measures are taken.

Sunday, June 19, 2011 06:59 +0900 (JST)

4 out of 5 want nuclear reactors scrapped in Japan

TOKYO, June 19, Kyodo

More than four out of five Japanese want the nation's 54 nuclear reactors to be decommissioned either immediately or gradually in the wake of the crisis at the Fukushima Daiichi nuclear plant, a poll reported by the Tokyo Shimbun daily showed Sunday.

Only 14 percent said the reactors should continue operations while 82 percent backed their decommissioning, showing a marked lack of confidence in the nation's atomic energy policy, according to the June 11-12 poll.

In a breakdown, a total of 54 percent of respondents said the reactors should be decommissioned "while taking into account the power supply-and-demand situation," followed by 19 percent who want decommissioning to "start with ones undergoing periodic checks" and 9 percent who called for immediate scrapping of nuclear plants.

Fukushima parents decontaminate school building

Parents and teachers decontaminated an elementary school building in Date City, Fukushima Prefecture, on Sunday.

About 80 parents and teachers at Tsukidate elementary school thoroughly washed windows and verandas with high-pressure water jets and brushes.

The school has not detected radiation levels in excess of the legal limit, but has still suspended activities on the playground in response to concern by parents.

Meanwhile, radiation levels exceeded the limit in some parts of the city, and the government plans to help households in the designated areas to evacuate, raising concern among residents.

One parent who participated in the clean-up said he wanted to do something for children because the government's response has been slow.

School principal Masayoshi Murakami says he hopes the clean-up will help to ease children's and parents' worries.

Sunday, June 19, 2011 16:54 +0900 (JST)

Radioactive reactor equipment may be exposed at Fukushima plant (kyodonews 19 juin)

TEPCO opens doors at No.2 reactor

Tokyo Electric Power Company says it has opened the doors and begun ventilation at the No. 2 reactor of the Fukushima Daiichi nuclear plant.

The restoration work inside the No. 2 reactor has been hampered by humidity of almost 100 percent due to steam from the containment vessel and spent-fuel storage pool.

TEPCO opened the doors halfway at 8:51 PM on Sunday. **It plans to fully open them at 4 AM on Monday if there are no problems.**

The utility has been using an air purification device for more than a week to reduce the radioactive

concentration inside the building.

The firm calculated that the level of background radiation around the plant after opening the doors would be 0.0014 microsieverts per hour. The annualized figure would be far below the permissible limit of one millisievert a year.

A TEPCO official told reporters on Sunday that the planned door-opening will have almost no impact on the nearby environment.

TEPCO says it has explained the plan to Fukushima Prefecture and 13 local municipalities. It says that when the doors are fully open, it will begin checking radiation levels and adjusting meters inside the building.

Monday, June 20, 2011 00:03 +0900 (JST)

Decontamination equipment failure to be analyzed

Tokyo Electric Power Company started an experiment on Sunday night to determine the cause of a sudden rise in radiation levels that caused a water decontamination system to shut down.

The operator of the Fukushima Daiichi nuclear power plant suspects that greater than anticipated amounts of contaminated oil and sludge entered part of the system.

The utility put the new system into full operation on Friday night to remove radioactive materials from the highly contaminated water that has accumulated in the plant.

The operation had to be suspended after just 5 hours as the radiation level of equipment that removes oil and sludge rose to 4 millisieverts per hour, the level at which it needs to be replaced.

TEPCO had initially expected the equipment to last for about a month before it had to be changed.

The utility says greater than anticipated amounts of material containing radioactive substances may have flowed into the device, causing the radiation level to rise rapidly.

The company started an experiment on Sunday night to compare an oil absorbent with the material currently being used, to determine the cause of the sudden rise in radiation levels.

The resumption of a full-fledged operation will depend on the outcome of the experiment.

The amount of contaminated water is growing by 500 tons a day as fresh water is continuously being injected into the reactors to cool them down.

TEPCO is working to identify the cause of the series of problems and to take measures to resolve them, as the storage facilities for the contaminated water are filling up.

A delay in resuming the system could cause the water to overflow in about a week.

French uranium challenge to Kakadu heritage listing

Lindsay Murdoch, Darwin <http://www.theage.com.au/national/french-uranium-challenge-to-kakadu-heritage-listing-20110619-1ga6o.html>

June 20, 2011

Jeffrey Lee, the senior custodian of the land that includes the Koongarra project area, would be one of Australia's richest people if he allowed the uranium mine to go ahead. *Photo: Glenn Campbell*

A FRENCH government-owned company attempted to block countries discussing an Australian request to expand the World heritage-listed Kakadu National Park to include land that contains uranium worth billions of dollars.

Paris-based Areva, the world's largest nuclear energy company, wants to extract 14,000 tonnes of uranium from its mineral lease in the Koongarra area, which is surrounded by the park. But federal Labor made an election promise last year to incorporate Koongarra into Kakadu, removing the possibility of future uranium mining there.

Areva formally requested Australia to withdraw its nomination for heritage listing from the agenda of the 35th World Heritage Committee meeting, which will be held in Paris this week, *The Age* has learnt.

But the government rejected the request and has sent a six-member delegation to Paris to push the nomination.

Jeffrey Lee, the sole member of the Djok clan and senior custodian of the land that includes the 12.5 square kilometre Koongarra project area, has also travelled to Paris hoping to speak at the meeting.

Mr Lee, 40, who would be one of Australia's richest people if he allowed the mine to go ahead, told *The Age* he wanted to tell the story of his country, which he wanted to see protected forever in the park.

"I've waited too long for this to happen," said Mr Lee, who works as a ranger in Kakadu.

Koongarra is an ecologically sensitive area three kilometres from Nourlangie Rock, one of Kakadu's most visited sites.

According to Aboriginal beliefs, the land has places where the rainbow serpent entered the ground and a giant blue tongue lizard still lurks.

The area also has rock art dating back thousands of years.

Federal Environment Minister Tony Burke told *The Age* his government would fight any opposition to the heritage nomination.

"I'm confident of the merit of our case," he said.

A high level World Heritage Committee delegation to Australia in 1998 recommended Koongarra be listed as "in danger" because of threats posed by uranium mining operations.

Areva Australia's website says the company owns the Koongarra uranium deposit, which was discovered in 1971, but there is currently a moratorium on mining it.

■ Mr Burke has put off until August a decision on whether to make a large part of Kimberley in Western Australia a national heritage-listed area.

He said he needed more time to consult and study the values of the recommended area and sites.

Under heritage listing the federal government would have to approve environmentally and culturally sensitive development projects.

Nuclear 1 to 10 incl

Another TEPCO worker exceeds radiation limit

Preliminary research shows another worker at the troubled Fukushima Daiichi nuclear power plant may have been exposed to radiation above the limit.

Tokyo Electric Power Company reported the results of radiation checks on more than 1,100 workers at the plant to the health and labor ministry on Monday.

The ministry said one of the workers -- part of the maintenance staff at the plant -- is suspected of having been exposed to 335 millisieverts.

The figure exceeds the limit of 250 millisieverts set by the government for emergency situations.

The checks came after TEPCO found 3 additional workers had been exposed to radiation beyond the legal limit. Five more workers are suspected of having received doses of radiation above the limit.

The ministry has told the utility to conduct checks and report the results on 125 other workers, who were engaged in operations at the plant in March but have not undergone radiation screening.

Monday, June 20, 2011 19:55 +0900 (JST)

Radioactive reactor equipment may be exposed at Fukushima plant

TOKYO (Kyodo) -- Highly radioactive equipment removed from and kept under water near a suspended reactor at the crippled Fukushima Daiichi nuclear power plant may be partially exposed and emitting radiation into the air, officials of the plant operator said **Sunday**.

Tokyo Electric Power Co. began injecting water for the equipment the same day at the building of the No. 4 reactor, which was suspended for regular inspection when it lost cooling functions in the March 11 earthquake and tsunami, the officials said.

Since a pool containing nuclear fuel that had been taken out of the reactor cannot be cooled, water is evaporating and causing a pit connected to it, with equipment including a shroud to adjust the flow of coolant water and a steam dryer inside, to also lose water.

The 7.6 meter-deep pit contained water, which shields against radiation, only up to 2.5 meters as of June 11 and the highly radioactive part of the shroud, that was originally 6.8 meters in height but has been cut to fit in the pit, may be exposed to the air, the officials said.

But the fuel in the storage pool is not believed to have been exposed or suffered damage, probably because water from the pit helped slow the reduction of water in the pool, company spokesman Junichi Matsumoto told a press conference.

The utility known as TEPCO, meanwhile, began releasing air possibly containing low levels of radioactive substances from the No. 2 reactor building in the evening by gradually opening the doors through early Monday.

The step, which will take hours to prevent the stirring up of dust containing toxic materials, is aimed at lowering the over 99 percent humidity inside to enable work to be conducted there, TEPCO said, denying that the move will have an impact on the environment.

After the venting, TEPCO will start injecting nitrogen into the reactor to prevent a hydrogen explosion and adjusting measuring equipment, it said.

(Mainichi Japan) June 20, 2011

Test of decontamination system continues

The operator of the damaged Fukushima power plant is struggling to fix the problem that caused the suspension of a system to decontaminate highly radioactive wastewater.

The system is designed to filter radioactive material, oil and salt from the contaminated water and to reuse the treated water to cool the reactors.

Tokyo Electric Power Company, or TEPCO, halted the filtering system only 5 hours after it went into full operation on Friday. Readings around one of the system's devices indicated higher-than-expected radiation levels.

TEPCO engineers suspect that the density of radioactive substances in the contaminated water was greater than had been predicted.

They initially thought that the device had absorbed large volumes of oil and sludge containing radioactive material. But in a test conducted on Sunday, high radiation levels were registered for equipment set to the lowest of 3 absorption levels.

In another test on Monday, TEPCO adjusted the flow of the contaminated water through the equipment.

The radioactive wastewater is hampering work to bring the plant under control. The amount is increasing by 500 tons a day as fresh water is continuously being injected to cool the reactors. Storage facilities are filling up and a delay in restarting the filtering system could cause the water to overflow in about a week.

Monday, June 20, 2011 14:17 +0900 (JST)

Lowering humidity underway at reactor No.2

The operator of the damaged Fukushima Daiichi plant says the high humidity inside one of the reactor buildings has been lowered after an entrance was opened to vent air. It plans to bring the humidity low enough for workers to work inside by opening up another entrance.

Restoration work inside the No. 2 reactor building has been hampered by nearly 100% humidity caused by steam believed to be from the containment vessel and spent-fuel storage pool.

Tokyo Electric Power Company opened the entrance early Monday morning after it had filtered

radioactive substances from the air inside the building.

The utility says the humidity levels near the entrance and at other points has been lowered to around 60%.

But it says the reading near a cargo entrance, that utility plans to open on Monday afternoon, was still nearly 90%.

It hopes workers will be able to enter the building to begin calibrating a water level gauge for the reactor and other tasks.

The utility says radiation readings were between 5 and 27 millisieverts per hour inside, but no significant change in radiation levels has been observed outside the plant.

The No.2 reactor is believed to have released more radioactive substances than the other reactors at the plant after an explosion apparently damaged its suppression chamber.

The government has asked the utility to look into what exactly happened after the disaster along with efforts to stabilize the reactor.

Monday, June 20, 2011 13:21 +0900 (JST)

Tepco s'efforce de restaurer rapidement le système de décontamination d'eau radioactive

La Compagnie d'électricité de Tokyo, Tepco, s'efforce de restaurer un système de décontamination d'eau radioactive qui a dû être désactivé vendredi après une courte période de fonctionnement.

L'opérateur de la centrale a effectué un test de plus de quatre heures dans la nuit de dimanche pour déterminer les causes d'une élévation rapide de la radioactivité dans le système.

Les ingénieurs de Tepco pensent que la densité de substances radioactives dans l'eau contaminée dépassait les prévisions.

Ils pensaient à l'origine que le dispositif avait absorbé de grandes quantités d'huile et de boue contenant des substances radioactives. Mais un test effectué dimanche a montré que des taux élevés de radiation étaient enregistrés lorsque le dispositif était réglé sur le niveau d'absorption le plus faible des trois disponibles.

Le volume d'eau radioactive augmente de 500 tonnes par jour, de l'eau douce étant continuellement injectée dans les réacteurs pour les refroidir.

Les installations de stockage d'eau contaminée se remplissent et tout retard pris dans la remise en marche du système pourrait aboutir à des débordements dans environ une semaine.

Tepco aère le bâtiment du réacteur 2 pour abaisser le taux d'humidité

Selon Tepco, l'humidité élevée à l'intérieur d'un des bâtiments des réacteurs a baissé après que la compagnie a pratiqué une ouverture pour évacuer l'air.

Les travaux de restauration à l'intérieur du bâtiment du réacteur 2 ont été rendus difficiles par un taux d'humidité de près de 100 pour cent provoqué par de la vapeur qui s'échapperait de l'enceinte de confinement et de la piscine de stockage de combustible irradié du réacteur.

La compagnie a pratiqué l'ouverture lundi matin après avoir filtré les substances radioactives contenues dans l'air à l'intérieur du bâtiment.

L'opérateur de la centrale estime que le taux d'humidité à proximité de l'ouverture et en plusieurs autres points a été abaissée à environ 60 pour cent.

Tepco espère que les techniciens pourront pénétrer dans le bâtiment pour commencer à étalonner une jauge de niveau d'eau pour le réacteur et effectuer d'autres opérations.

TEPCO injects water to No.4 reactor storage pool

Tokyo Electric Power Company has been trying to reduce a high level of radiation discovered in the Number 4 reactor of the troubled Fukushima Daiichi nuclear power plant.

The utility started to inject water into a pool on the top floor which was used for storing large equipment contaminated by radiation on Sunday.

The Number 4 reactor was shut down for a routine inspection when it was hit by the earthquake and the tsunami on March 11th.

Large hardware in the reactor was removed and was submerged in the pool to block the release of radiation.

Tokyo Electric Company discovered that the water level of the pool had dropped to about 1/3 of its capacity as of June 11th.

The machinery is thought to have been exposed and releasing high amounts of radiation.

The operator fears it could hamper restoration work in the Number 4 reactor.

TEPCO says the radiation level on the top floor is so high that workers cannot enter, but if the equipment is submerged again, the radiation level will decline enabling operations to restart.

Tepco injecte de l'eau dans une piscine de stockage du réacteur 4

La Compagnie d'électricité de Tokyo, Tepco, s'efforce de réduire le taux élevé de radiation découvert dans le réacteur 4 de la centrale nucléaire Fukushima Dai-ichi.

L'opérateur de la centrale a commencé dimanche à injecter de l'eau dans une piscine au niveau supérieur du bâtiment du réacteur 4, utilisée pour stocker du matériel lourd contaminé par les radiations.

Le réacteur numéro 4 était fermé pour une inspection de routine lorsqu'il a été frappé par le séisme et le tsunami du 11 mars.

Du matériel lourd provenant du réacteur a été enlevé et plongé dans la piscine pour enrayer la production de rayonnements ionisants.

Tepco a découvert que le niveau de l'eau de la piscine avait baissé à environ un tiers de sa capacité le 11 juin.

Le matériel en question aurait été exposé à la radioactivité et produirait des taux élevés de radiation.

L'opérateur craint un ralentissement des travaux de restauration dans le réacteur 4 du fait de la radioactivité élevée.

Ainsi, selon Tepco, le taux de radiation au niveau supérieur du bâtiment est si élevé que les techniciens ne peuvent pas y entrer. Néanmoins, si le matériel est de nouveau submergé la radioactivité baissera, permettant la reprise des opérations.

It doesn't take a tsunami...

June 15, 2011
admin

...as this AP picture shows, with the Ft. Calhoun nuclear power plant in Nebraska now completely surrounded by water as levels continue to rise in the Missouri River.

Following the June-July 1993 flooding along the Missouri River, the NRC published [Information Notice](#) 94-27 which revealed that while giving safety assurances to the public during the flooding around the Cooper nuclear power station near Brownville, Nebraska, water was actually coming into the reactor building and rising on safety-related electrical circuits vital to reactor cooling even with the unit in shutdown. Floor drains can become fountains. There is additional concern from rising flood water inundating an on-site auxiliary building and the reactor's "spent" fuel storage pool now located on the nuclear island in our midwest.

Article originally appeared on Beyond Nuclear (<http://www.beyondnuclear.org/>).

See website for complete article licensing information.

Le ministère de l'Environnement a décidé d'approuver l'incinération de décombres contaminés par la radioactivité (post catastrophe de Fukushima) dans les usines d'incinération existantes équipées de filtres et de dispositifs d'absorption (?)

Mise en place de cette mesure dès la fin du mois de juin.

L'idée est que les résidents ne seront pas exposés à + de 10 microsieverts de radiation par an.

Les décombres contenant moins de 8000 becquerels de césium par kilo pourront être enfouis une fois brûlés dans des décharges ordinaires. Mais le gouvernement interdira que ces sites puissent servir à la construction de zones résidentielles à l'avenir.

Provisoirement les cendres (moins de 8000 becquerels de césium) récupérées par les filtres spéciaux et les cendres résultant de l'incinération devront être conservées dans des « bidons spéciaux capables de bloquer la radioactivité ».[ça existe ce genre de bidon ?] Les cendres contenant plus de 100 000 becquerels devront être conservées dans des installations protégées par des murs de béton.

Il n'existe actuellement aucune loi sur les façons de disposer des déchets radioactifs résultant de la destruction d'une centrale nucléaire (donc le gouvernement a fait avec les lois existantes).

Environment Ministry to approve incineration of rubble contaminated with radiation

Rubble piles up at a temporary disposal site in Iwaki, Fukushima Prefecture. (Mainichi)

The Environment Ministry has decided to approve the proposed incineration of rubble contaminated with radiation from the tsunami-hit Fukushima nuclear power plant at existing incineration facilities equipped with exhaust gas filters and absorption devices, officials said.

It made the decision after discussing how to safely dispose of rubble contaminated with radiation from the crippled Fukushima No. 1 Nuclear Power Plant.

The ministry had initially urged local governments not to move radioactive rubble out of temporary storage sites. However, it will explain its decision to local governments concerned and ask them to resume their disposal of contaminated rubble **as early as the end of this month.**

In working out basic policy for the disposal of radioactive rubble, the ministry principally followed the procedure of treating radioactive sludge from sewage disposal facilities near the plant.

The policy is based on the assumption that residents near disposal sites will be exposed to less than 10 microsieverts of radiation a year.

The ministry will allow local governments to bury burned rubble containing less than 8,000 becquerels of radioactive cesium per kilogram of rubble at waterproof final disposal sites for ordinary waste. However, the ministry will ban such disposal sites from being converted to residential areas in the future.

Authorities will also require local bodies to temporarily store ash caught by exhaust gas filters and ash from burned rubble containing more than 8,000 becquerels of radioactive cesium in **special drums that can block radiation** and ash containing over 100,000 becquerels of radiation at facilities shielded by concrete walls.

The ministry has ordered that levels of radiation must be thoroughly monitored at facilities where incinerated radioactive rubble is temporarily stored.

Moreover, the ministry will permit local governments to bury sludge created by the tsunami generated by the March 11 Great East Japan Earthquake, concrete fragments and other nonburnable waste at final disposal sites for ordinary waste.

Metal and other recyclable waste can be reused on condition that they emit less than 0.01 millisieverts of radiation per year and therefore are not legally regarded as radioactive substances.

No law currently provides for ways to dispose of waste contaminated with radiation from a crippled nuclear power plant. After consultations between ministries and agencies concerned, the government decided to apply the Waste Disposal and Public Cleaning Law to the disposal of radioactive rubble.

The government will also try to form a consensus among Fukushima residents about its plan to build final disposal sites for radioactive waste in the prefecture.

TEPCO struggles to resume key water treatment system at Fukushima

TOKYO (Kyodo) -- Tokyo Electric Power Co. continued struggling Monday to figure out how to cope with difficulties in operating a newly installed water treatment system at its troubled Fukushima Daiichi nuclear power plant, aiming to resume its full operation as early as Tuesday.

Smooth operation of the system, which is designed to remove highly radioactive materials from a massive amount of water accumulating at the station, is considered essential to containing the three-month-old nuclear crisis, as the utility plans to eventually recycle the water to cool the plant's damaged reactors.

But the newly installed system was halted at 12:54 a.m. Saturday, after becoming fully operational at 8 p.m. Friday, because the radiation level of a component to absorb cesium had reached its limit and required replacement earlier than expected, the plant operator said.

The utility, known as TEPCO, has been analyzing why the component has not worked well and how to solve the problem, the firm's officials said.

"I think we can resume operating the system in a day or so," TEPCO spokesman Junichi Matsumoto said at a press conference, emphasizing that it will not take a long time before the company will come up with measures to decontaminate high-level radioactive water.

While dealing with the tainted water, TEPCO said Monday it fully opened the doors of the No. 2 reactor building at the power station to lower humidity inside to enable people to work there, denying the move would have an impact on the environment.

The ventilation has helped reduce the humidity inside, the government's nuclear safety agency said, adding that the level declined to 58.7-89.9 percent from as high as 99.9 percent measured before the doors were opened.

If the level of humidity decreases to around 70 percent, people can work inside the building with full-face masks, which could allow TEPCO to start injecting nitrogen into the reactor to prevent a hydrogen explosion and adjust measuring equipment there, the Nuclear and Industrial Safety Agency said.

In other progress, a robot called "Quince" -- jointly developed by Japan's Chiba Institute of Technology, Tohoku University and other institutions -- will be sent to the Fukushima power complex, the agency said.

Quince is capable of operating in places where rubble is scattered and is believed to be able to measure levels of radiation inside buildings and depths of contaminated water, as well as obtain samples of such water, as it can climb wet and slippery steps, the agency added.

Still, TEPCO also said Monday that one more worker involved in efforts to tackle the nuclear crisis at the power station was found to have been exposed to radiation above the maximum allowable limit of 250 millisieverts, bringing the total number of such workers to nine.

In this May 27, 2011 photo released on June 2, 2011 by Tokyo Electric Power Co. (TEPCO), temporary storage tanks for low-level radioactive polluted waters used for temporary cooling system in Fukushima Dai-ichi nuclear power plant in Okuma, Fukushima prefecture, northeastern Japan, are shown. (AP Photo/Tokyo Electric Power Co.)

The latest announcement was made as the utility is checking the external and internal radiation exposure of a total of more than 3,500 workers who were engaged in the emergency work in March, after the devastating March 11 earthquake and ensuing tsunami crippled the plant.

The government will "have the responsibility to implement thorough measures" to prevent workers at the complex from being excessively exposed to radiation, Goshi Hosono, a special adviser to Prime Minister Naoto Kan on the handling of the nuclear disaster, said at a press conference.

(Mainichi Japan) June 20, 2011

quand le maintien des actions TEPCO à un niveau acceptable pour les actionnaires est plus important que d'essayer d'empêcher la contamination de la nappe phréatique (et de l'océan) par la radioactivité.

Comment TEPCO est incapable de voir la « barrière souterraine » sous les réacteurs autrement qu'en fonction de la réaction de ses actionnaires.

Preventing radiation contamination more important than TEPCO's stock prices

In this June 1, 2011 file photo released by Tokyo Electric Power Co. (TEPCO), workers inspect equipment inside the cesium absorption tower, part of the radioactive water processing facilities at the Fukushima No. 1 Nuclear Power Plant in Okuma, Fukushima Prefecture. (AP Photo/TEPCO)

Some people have suggested that I start to write about something other than nuclear power plants, but with the situation as it is, that's not going to happen. The crisis at the Fukushima No. 1 Nuclear Power Plant is still not over. Far from it, there are signs that it is getting worse. I can't stand by and look at the political situation without focusing on this serious event.

One figure who has entered the public spotlight in the wake of the nuclear crisis is 61-year-old **Hiroaki Koide**, an assistant professor at the Kyoto University Research Reactor Institute and a controversialist in the anti-nuclear debate. A specialist in nuclear power, Koide has garnered attention as a persistent researcher who has sounded the alarm over the dangers of this form of energy without seeking fame.

In a TV Asahi program on June 16, Koide made the following comment:

"As far as I can tell from the announcements made by Tokyo Electric Power Co. (TEPCO), the nuclear fuel that has melted down inside reactors at the Fukushima nuclear plant has gone through the bottom of the containers, which are like pressure cookers, and is lying on the concrete foundations, sinking into the ground below. **We have to install a barrier deep in the soil and build a subterranean dam as soon as possible to prevent groundwater contaminated with radioactive materials from leaking into the ocean.**"

In this photo taken on Thursday, March 31, 2011 by Japan Maritime Self-Defense Force and released by Japan Defense Ministry Friday, April 1, JMSDF personnel all in protective suits are aboard a tugboat towing a U.S. military barge carrying pure water towards the quay of the tsunami-stricken Fukushima Dai-ichi nuclear complex in Okumamachi, Fukushima Prefecture, northeastern Japan. (AP Photo/Japan Defense Ministry)

His comment captured public interest and when I asked a high-ranking government official about it, the official said that construction of an underground dam was indeed being prepared. But when I probed further, I found that the project was in limbo due to opposition from TEPCO.

Sumio Mabuchi, an aide to Prime Minister Naoto Kan who is dealing with nuclear power plant issues, holds the same concerns as those expressed by Koide and has sought an announcement on construction of an underground dam, but TEPCO has resisted such a move.

The reason is funding. It would cost about 100 billion yen to build such a dam, but there is no guarantee that the government would cover the amount. If an announcement were made and TEPCO were seen as incurring more liabilities, then its shares would fall once again, and the company might not be able to make it through its next general shareholders' meeting.

In my possession, I have a copy of the guidelines that TEPCO presented to the government on how to handle press releases. The title of the document, dated June 13, is "Underground boundary' -- Regarding the press." It is split into five categories on how to handle the announcement of construction of an underground boundary. In essence, it says, "We are considering the issue under the guidance of prime ministerial aide Mabuchi, but we don't want to be seen as having excess liabilities, so we're keeping the details confidential."

Possibly the silliest response to envisaged questions from reporters is TEPCO's suggestion for a reply to the question, "Why hasn't construction been quickly started?" The response reads: "Underground water flows at a speed of about 5 to 10 centimeters a day, so we have more than a year before it reaches the shore."

Initially an announcement on the underground barrier was due to be made to the press on June 14, but it was put off until after TEPCO's general shareholders meeting on June 28.

In the meantime, the state of the nuclear power plant continues to deteriorate and radioactive materials are eerily spreading and contaminating the area around the plant.

Which is more important: upholding share prices or stopping pollution? The Japanese political and business world has sunk to a level where it can't even answer such a question.

One government official recently commented, "I think I can understand now why the leaders during the war couldn't precisely and steadily accomplish their strategies."

Today, announcements from the "imperial headquarters" -- namely TEPCO's releases on its roadmap for bringing the nuclear crisis under control, which nobody believes -- are still being issued.

Some people have compared Kan to former Japanese Prime Minister Hideki Tojo, because he yells at his subordinates over the smallest details. Tojo resigned in July 1944, after the fall of Saipan, when it had become likely that Japan would lose the war. His successor, Kuniaki Koiso, was in office for 8 1/2 months before being replaced by Kantaro Suzuki. After this, two atomic bombs were dropped on Japan and then the war ended after a decision from the Emperor.

In this Friday, March 18, 2011 satellite image released by DigitalGlobe, the Fukushima Dai-ichi is shown. (AP Photo/DigitalGlobe)

Why wasn't an armistice quickly implemented to put an end to further wartime damage? It was because impossible solutions to Japan's situation in the war were flying about, common sense was lost, and the government was slow to reach a decision. Yet the same sort of situation has arisen today.

The most important issue now is preventing contamination from radiation. We need leaders who can focus on the core issue without being swayed by empty theory. (By Takao Yamada, Expert Senior Writer)

Accidents de réacteur Inondation à Fort Calhoun (Reactor Accidents FLOOD at FORT CALHOUN)

de : **un anonyme**

lundi 20 juin 2011 (15h29)

2 commentaires

Traduction (anglais > français) Juin 15, 2011, mis à jour Juin 19, 2011

Inondation de la rivière Missouri menace Nebraska Fort Calhoun réacteur nucléaire, détenue et exploitée par le District Omaha Public Power. Ci-dessus est une photo du site de Fort Calhoun prise le 11 juin 2011. Une brève vidéo du site du 14 juin est disponible [ici](#) (la partie montrant Fort Calhoun commence à 1 minute 21 secondes dans la vidéo et dure environ 5 secondes, de sorte que vous pouvez mettre en pause).

Le réacteur de Fort Calhoun est actuellement en arrêt à froid et a été depuis le 9 avril 2011, quand il a commencé un arrêt pour rechargement. Le processus de ravitaillement est terminé et le réacteur est maintenant une gamme complète de carburant - 1 / 3 frais (inutilisées) de combustible et de carburant 2 / 3 âgés et hautement radioactifs. Le réacteur n'a pas été redémarré depuis l'arrêt pour rechargement commencé.

La piscine Fort Calhoun de carburant se trouve dans le bâtiment des auxiliaires (bâtiment marron à la droite du bâtiment de confinement blanc en photo ci-dessus). La piscine elle-même est d'environ 30 pieds au-dessus du niveau du sol. La piscine contient actuellement environ 670 tonnes de combustible irradié. A propos de 165 tonnes de combustibles irradiés sont entreposés dans des fûts de sécheresse sur le site (emplacement de la photo ci-dessus inconnu). Ensemble, ce carburant contient environ 100 millions de curies de radiation, de 40% de ce qui est Césium-137. Des déchets irradiés Ce seul réacteur contient donc plus que de césium-137 a été rapporté avoir été libérés à ce jour par les réacteurs de Fukushima quatre.

Le site du réacteur est 1004 pieds au-dessus du niveau de la mer. Le niveau d'eau est actuellement, selon la Nuclear Regulatory Commission, à 1005 pieds, 7 pouces au-dessus du niveau des mers et il est prévu d'augmenter à 1006 pieds, 4 pouces. Ce niveau d'inondation est projetée pour durer pendant des semaines. Toutefois, cette projection suppose une pluviométrie normale dans les prochaines semaines et aucune défaillance de digues en amont - deux facteurs qui pourraient causer une étape supérieure d'inondation. L'utilitaire (Omaha Public Power District) a mis une berme de 8 pieds en caoutchouc

contre les inondations autour de la centrale et elle pense qu'elle peut résister à une crue jusqu'à environ 1010 pieds au-dessus du niveau des mers.

Deux événements importants ont eu lieu à Fort Calhoun, depuis que les eaux ont commencé à augmenter. Le 7 Juin, un incendie dans une switchroom électriques privé de courant, et la capacité de ce refroidissement, à la piscine de combustible pendant environ 90 minutes. Utilitaires responsables affirment qu'il faudrait 88 heures de perte de refroidissement de l'eau pour bien faire bouillir. Toutefois, puisque certains des combustibles dans la piscine a été chargé depuis le 9 avril et est donc très chaud, cela peut avoir été une estimation trop optimiste.

Le 13 Juin, les eaux usées de la construction de l'administration du site a été libéré dans la rivière Missouri au taux de 105 gallons par minute. Nous avons été incapables de déterminer combien de temps cette libération a eu lieu. Depuis les eaux usées seraient venus de l'immeuble administratif, il n'était pas susceptible d'avoir contenu des rayonnements.

Le 17 Juin, OPPD émis un avis d'une vulnérabilité potentielle des inondations - un trou dans un sol - qui pourraient avoir affecté un système de sécurité. OPPD devait sceller le trou plus tard ce jour.

Selon une entrée mise à jour dans Wikipedia : «Une évaluation réalisée par les inondations de la Nuclear Regulatory Commission en 2010 a indiqué que la station de Fort Calhoun nucléaire», n'a pas de procédures adéquates pour protéger la structure d'admission et bâtiment des auxiliaires contre les inondations externes "[. 6] L'évaluation a également indiqué que l'installation n'était pas suffisamment préparé pour un "pire" scénario d'inondation. Un certain nombre de points d'inondation potentiel de pénétration de l'eau ont été découverts qui pourraient avoir affecté l'approvisionnement en aliments crus d'eau pour le système de refroidissement, l'eau axillaires l'offre et de commutation principal (électrique) chambre. Au début de 2011, des mesures correctives avaient été mises en œuvre [6]. "

Fort Calhoun est un 500 MW Combustion Engineering réacteur à eau pressurisée. Il a reçu sa licence d'exploitation initiale en Octobre 1973, et un renouvellement de sa licence en 2003. Il est maintenant autorisé à opérer jusqu'en août 2033. La Nuclear Regulatory Commission considère actuellement Fort Calhoun à être l'un des trois réacteurs les plus problématiques dans les Etats-Unis en raison de problèmes de sécurité en cours dans le réacteur, et le site a été sous surveillance accrue pendant quelque temps. Sur Juin 16, le CNRC a envoyé des inspecteurs supplémentaires sur le site pour examiner les préparatifs d'inondation.

est au-dessous une photo de Fort Calhoun dans des conditions normales.

Le réacteur nucléaire de Cooper dans le Nebraska, également sur la rivière Missouri, est également l'objet de préoccupations des inondations. Cooper est un réacteur de GE Mark I, comme les réacteurs qui ont échoué à Fukushima. Trois travailleurs ont été exposés aux radiations ce printemps à la Cooper, et à la mi-Juin de l'utilité a été cité par le CNRC pour les carences prévention des incendies. Une notification de cas inhabituel - le plus bas des catégories du CNRC de sécurité 4 - a été déclaré dimanche, Juin 19 à réacteur Cooper en raison de crue des eaux. A cette époque, cependant, les inondations ne devrait pas contester le réacteur, mais beaucoup dépend de la hauteur des eaux atteint au cours des prochaines semaines.

Info NIRS <http://www.nirs.org/reactorwatch/ac...>

post scriptum : croisons les doigts pour que tout aille bien ! prions ensemble ! Sortons du nucléaire Maintenant !

June 15, 2011, updated June 19, 2011

Flooding on the Missouri River is threatening Nebraska's Fort Calhoun nuclear reactor, owned and operated by the Omaha Public Power District. Above is a photo of the Fort Calhoun site taken June 11, 2011. [A brief video of the site on June 14 is available here](#) (the portion showing Fort Calhoun starts at 1 minutes 21 seconds into the video and lasts about 5 seconds, so you may want to pause it).

The Fort Calhoun reactor is currently in cold shutdown and has been since April 9, 2011, when it began a refueling outage. The refueling process is complete and the reactor is holding a full complement of fuel--1/3 fresh (unused) fuel and 2/3 older and highly radioactive fuel. The reactor has not been restarted since the refueling outage began.

The Fort Calhoun fuel pool is in the auxiliary building (brown building to the right of the white containment building in photo above). The pool itself is about 30 feet above ground level. The pool currently contains about 670 metric tons of irradiated fuel. About 165 tons of irradiated fuel are stored in dry casks at the site (location in photo above unknown). Together this fuel contains about 100 million curies of radiation, 40% of which is Cesium-137. This single reactor's irradiated waste thus

contains more Cesium-137 than has been reported to have been released to date from the four Fukushima reactors.

The reactor site is 1004 feet above sea level. The water level is currently, according to the Nuclear Regulatory Commission, at 1005 feet, 7 inches above sea level and is projected to rise to 1006 feet, 4 inches. This flood stage is projected to last for weeks. However, that projection assumes normal rainfall in the coming weeks and no failure of upstream levees--two factors which could cause a higher flood stage. The utility (Omaha Public Power District) has put an 8-foot rubber flood berm around the plant and believes it can withstand a flood up to about 1010 feet above sea level.

Two significant events have occurred at Fort Calhoun since the flood waters began to rise. On June 7, [a fire in an electrical switchroom](#) knocked out power, and thus cooling capability, to the fuel pool for about 90 minutes. Utility officials claim it would take 88 hours of loss of cooling for the water to fully boil off. However, since some of the fuel in the pool has been loaded since April 9 and is thus quite hot, this may have been an overly optimistic estimate.

On June 13, sewage from the site's administration building was released into the Missouri River at the rate of 105 gallons per minute. We have been unable to determine how long this release took place. Since the sewage reportedly came from the administration building, it was not likely to have contained radiation.

On June 17, OPPD issued a notice that of a potential flooding vulnerability--a hole in a floor--that could have impacted one safety system. OPPD was expected to seal the hole later that day.

According to an updated entry in [Wikipedia](#): "A flood assessment performed by the Nuclear Regulatory Commission in 2010 indicated that the Fort Calhoun Nuclear Generating Station, "did not have adequate procedures to protect the intake structure and auxiliary building against external flooding events."[\[6\]](#) The assessment also indicated that the facility was not adequately prepared for a "worst-case" flooding scenario. A number of potential flood water penetration points were discovered that could have impacted the raw feed water supply to the cooling system, the auxiliary water supply and main switchgear (electrical) room. By early 2011, corrective measures had been implemented.[\[6\]](#)"

Fort Calhoun is a 500 MW Combustion Engineering Pressurized Water Reactor. It received its initial operating license in October 1973, and a renewal of its license in 2003. It is now licensed to operate until August 2033. The Nuclear Regulatory Commission currently considers Fort Calhoun to be one of the three most problematic reactors in the U.S. because of ongoing safety issues at the reactor, and the site has been under enhanced oversight for some time. On June 16, the NRC sent additional inspectors to the site to review flood preparations.

below is a photo of Fort Calhoun under normal conditions.

Commentaire sur l'arrêt du système de décontamination

Pour notre commentaire d'aujourd'hui, nous avons demandé au professeur Akio Koyama, de l'Institut du réacteur de recherche de l'université de Kyoto, de nous parler de l'arrêt provisoire du système de décontamination d'eau à la centrale nucléaire Fukushima Dai-ichi.

Radio Japon

Ce système de décontamination d'eau est constitué de plusieurs modules, parmi lesquels un dispositif d'élimination d'huile, une unité pour absorber les substances radioactives et une autre pour les précipiter. Le problème le plus récent dont a été victime le système s'est produit lors de la deuxième étape, c'est-à-dire celle de l'absorption des substances radioactives. Quelle est l'origine de ce problème ?

Akio Koyama

Le dispositif d'élimination d'huile est conçu pour enlever une quantité suffisante d'huile et de boue radioactives. Mais je pense qu'un volume insuffisant a été éliminé dans ce cas. Après avoir traité l'eau avec ce dispositif, l'opérateur a fait passer l'eau dans l'unité chargée d'absorber les substances radioactives. Cette unité a pour fonction d'absorber les substances ionisées et dissoutes dans l'eau, ce qui la rend peu efficace pour traiter les impuretés telles que l'huile et la boue.

L'étape suivante consistait à précipiter les substances radioactives. Mais avant d'effectuer cette opération à l'aide de produits chimiques, le dispositif commence par retirer diverses impuretés.

Lors de la dernière opération en date, le dispositif chargé de précipiter les impuretés allait être utilisé après l'unité d'absorption.

Cette décision a probablement été prise parce que l'élimination de l'importante quantité de césium présente dans l'eau était prioritaire. Je pense que la priorité aurait dû être d'éliminer les impuretés, dans ce cas.

Des enquêtes sont menées sur les raisons de l'arrêt du système de décontamination. En règle générale, il est préférable de ne pas laisser de l'huile s'introduire dans les dispositifs, ce qui pourrait provoquer un dysfonctionnement. Je propose par conséquent d'améliorer les fonctions du dispositif d'élimination d'huile avant que de l'eau soit injectée dans le système.

Radio Japon

Des problèmes similaires au dernier en date risquent-ils d'affecter le calendrier de restauration tout entier ?

Akio Koyama

A mon avis, l'opérateur de la centrale a essayé de trop faire et trop tôt, dans l'espoir de respecter la date limite qu'il s'était fixée. Mais même si le processus dans son ensemble subissait du retard à cause du dernier incident, ce retard n'aggraverait pas la situation dans la centrale, tant que l'état des réacteurs ne se dégrade pas.

Des problèmes supplémentaires pourraient survenir, aussi le calendrier pourrait nécessiter des modifications.

C'était le professeur Akio Koyama, de l'Institut du réacteur de recherche de l'université de Kyoto, qui nous parlait de l'arrêt provisoire du système de décontamination d'eau à la centrale de Fukushima.

Key water treatment system halts at Fukushima plant

FUKUSHIMA, Japan, June 21, Kyodo

Tokyo Electric Power Co. said Tuesday that a pump of a newly installed radioactive water treatment system at its crippled Fukushima Daiichi nuclear power plant **halted automatically** during its trial run early that morning, freezing the operation of the entire apparatus.

The utility said it believes that the pump, which is a component developed by France's Areva SA to inject chemicals into the key system to decontaminate radioactive materials, had stopped as it was **overburdened by excessive liquid flow**.

The plant operator, known as TEPCO, said it aimed to restart a trial run as early as Tuesday afternoon after adjusting the liquid flow.

Water decontamination test at Fukushima stops

The test run of a water decontamination system at the crippled Fukushima Daiichi nuclear power plant has again been halted due to a malfunction.

The operator, Tokyo Electric Power Company, had resumed testing the system early Tuesday morning after a previous stoppage.

Last Friday, the operation of the entire water treatment system was stopped after only 5 hours of its test-run as higher than expected radiation was detected in US-made equipment for absorbing radioactive materials. It replaced the key elements for their absorption.

The utility says this time a pump for the French-made decontamination equipment automatically stopped at around 7:20 AM on Tuesday, causing the operation of the entire system to halt.

It says the pump is used to add water to decrease the density of chemicals which break down radioactive substances. Apparently its malfunction was caused by too much water.

Tokyo Electric says it wants to resume operation as early as Tuesday afternoon by adjusting the amount of water input.

Tuesday, June 21, 2011 13:10 +0900 (JST)

Nouvel arrêt des essais du système de décontamination

L'essai d'un système de décontamination d'eau à la centrale nucléaire Fukushima Dai-ichi a de nouveau été arrêté à cause d'un dysfonctionnement.

L'opérateur de la centrale, la Compagnie d'électricité de Tokyo, ou Tepco, a repris l'essai du système ce mardi matin après un arrêt. Vendredi dernier, son fonctionnement avait dû être interrompu cinq heures seulement après le début du test, un taux de radiation plus élevé que prévu ayant été détecté dans un dispositif américain d'absorption de substances radioactives. Tepco avait alors remplacé plusieurs

pièces vitales du dispositif.

La compagnie indique que cette fois-ci, **une pompe du matériel de décontamination d'origine française s'est automatiquement arrêtée vers 7h20 du matin, entraînant la désactivation du système tout entier.**

Tepco explique que la pompe était utilisée pour ajouter de l'eau et réduire la densité des produits chimiques destinés à décomposer les substances radioactives.

Le dysfonctionnement serait apparemment dû à un volume d'eau trop important.

Tepco dit souhaiter reprendre les essais dès ce mardi après-midi en réglant le volume d'eau admis dans la machine.

Pool reinforcement continues at No.4 reactor

Tokyo Electric Power Company is continuing work to reinforce a spent fuel pool at the Number 4 reactor of the Fukushima Daiichi nuclear power plant.

The walls supporting the pool were heavily damaged by a hydrogen blast on March 15th, following the earthquake and tsunami 4 days earlier.

The pool contains 1,535 spent fuel rods and its weakened structure makes it vulnerable to future earthquakes.

TEPCO on Monday completed one stage of the reinforcement that began late last month. 32 iron pillars, each 8 meters tall and weighing 40 tons, were installed beneath the pool on the 2nd floor of the reactor building.

The utility plans to wrap the pillars in concrete by the end of next month.

TEPCO then plans to install the same type of circulatory cooling system used for the spent fuel pool at the No. 2 reactor.

It hopes to lower the temperature of the pool at the No. 4 reactor, which remains high at **around 86 degrees Celsius.**

But TEPCO found that the March 15th explosion damaged water pipes connected to the pool, which are integral parts of the cooling system.

City in Saitama Prefecture sets independent maximum radiation dose for children

KAWAGUCHI, Saitama -- The city government here has set the maximum radiation dose for children at **1.64 millisieverts per year**, making it the first local government in Japan to implement its own radiation exposure standard.

The tentative figure announced on June 20 is based on the International Commission on Radiological Protection (ICRP)'s 1 millisievert recommended maximum exposure to man-made radiation sources, plus Japan's average background radiation dose of 0.34 millisieverts and the average 0.3 millisieverts of annual exposure to cosmic radiation.

According to the Kawaguchi city government, the new annual exposure limit breaks down to a maximum hourly dose of 0.31 microsieverts, assuming a child spent eight hours a day outside. **Officials will take radiation measurements at 10 sites in the city once a week, starting in mid-July. If they find radiation levels at a site have exceeded the new municipal maximum, the city will restrict outdoor activities at surrounding nursery schools, kindergartens, primary and junior high schools to three hours a day.**

The Kawaguchi city government has already taken radiation measurements twice at the 10 sites, recording a top hourly dose of 0.16 microsieverts.

The new maximum dosage was set after the city received inquiries from worried parents and guardians, asking what they should do about their children should radiation exposure rise.

Asked if the city's move wouldn't spark confusion in other local governments, Kawaguchi Mayor Koshiro Okamura replied, "We shouldn't all have different regulations. The central government really needs to set a national radiation dose standard."

Accidental water flow into pool may have prevented fuel melting: TEPCO

This Saturday May 7, 2011 image from video footage released on Sunday May 8, 2011 by Tokyo Electric Power Co., shows spent fuel storage pool of the Unit 4 reactor building at the crippled Fukushima Dai-ichi nuclear power plant in Okuma town, Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

Tokyo Electric Power Co. (TEPCO) has released the results of an investigation into developments surrounding the No. 4 reactor at the Fukushima No. 1 Nuclear Power Plant and advised that water accidentally flowed into a spent fuel pool from an adjacent pool, barely avoiding fuel from melting.

If water had not been poured into the spent fuel pool, the No. 4 reactor would have been "in a very serious situation," TEPCO spokesman Junichi Matsumoto said, adding that the worst-case scenario would have been the melting of nuclear fuel.

The pool for spent fuel at the No. 4 reactor of TEPCO's Fukushima No. 1 nuclear power plant is pictured in this Feb. 1, 2005, file photo.(Mainichi)

According to the utility, the No. 4 reactor's fuel pool had been connected with a storage pool containing radioactive substances through mobile shield plates and their water levels were the same prior to the March 11 earthquake and tsunami.

The fuel pool lost its cooling functions due to power loss caused by the tsunami and its water level dropped due to evaporation. But the hydrogen explosion at the No. 4 reactor and other factors on March 15 shifted the shield plates, allowing water from the adjacent pool to pour in and restore the water level.

On March 20, TEPCO started pumping water into the fuel pool from outside, probably causing the shield plates to shut again and keeping the device storage pool's water at a low level.

In this March 24, 2011 file aerial photo taken by a small unmanned drone and released by AIR PHOTO SERVICE, damaged Unit 4 of the crippled Fukushima Dai-ichi nuclear power plant is seen in Okumamachi, Fukushima prefecture, northern Japan. (AP Photo/AIR PHOTO SERVICE)

TEPCO plans to pump 1,000 cubic meters of water into the storage pool to keep the devices submerged. "The devices do not generate heat but will be submerged because of the radiation dosage problem," a TEPCO official said.

TEPCO will finish installing 32 steel posts to support the fuel pool on June 20 before building a concrete wall to cover the pillars by the end of July to make the structure more quake-resistant.

Whereabouts of 30 nuclear power plant subcontractors unknown: Health Ministry

The whereabouts of **about 30 subcontractors who helped deal with the crisis at the crippled Fukushima No. 1 Nuclear Power Plant** is unknown, the Ministry of Health, Labor and Welfare said on June 20.

The workers are among some 3,700 who worked to control the disaster in March, the month the plant was struck by the Great East Japan Earthquake and tsunami.

The workers' names were listed in records showing that they had been loaned dosimeters, but when the plant's operator, Tokyo Electric Power Co. (TEPCO), contacted the companies they were associated with, **the companies replied that there was no record of those workers.**

The ministry has branded TEPCO's administration of workers "sloppy" and ordered the company to conduct an investigation to identify the workers.

"We don't know why there is no record of the workers. The records and dosimeters were managed by TEPCO and its administration can only be described as **sloppy**," a representative of the ministry's Labor Standards Bureau said.

Ministry officials said that 3,639 emergency workers were enlisted to handle the nuclear crisis in March. As of June 20, TEPCO had reported provisional radiation exposure figures for 3,514 workers to the ministry. The other 125 had not undergone tests for internal radiation exposure as of June 20. **TEPCO has asked cooperating companies to have 69 of these 125 workers tested.** The remaining 56 were either about to undergo tests or could not undergo tests due to illness.

Officials said that TEPCO managed records of workers who had been loaned dosimeters between the outset of the disaster and mid-April. **When workers were loaned dosimeters at the base isolation structure of the power plant and another area, the serial numbers of the dosimeters, the names of the companies involved in the work and the workers' names were recorded in handwriting.** But when TEPCO contacted the cooperating companies there was no record of some 30 of the 69 workers.

All of the workers who were not found on company records have returned their dosimeters. Records of their external radiation exposure remained, but none of the workers was exposed to radiation exceeding the limit of 250 millisieverts, officials said.

Since mid-April, records have been managed with bar codes and other means of identification, but the only way to identify workers at the plant before then is through handwritten records.

(Mainichi Japan) June 21, 2011

Personne ne semble savoir où sont passé 30 des sous-traitants qui ont travaillé au début de la crise à la centrale.

Ces ouvriers étaient censés avoir eu un dosimètre (qu'ils devaient rendre) mais jusqu'à la mi-avril, les papiers/documents ont été écrits à la main et c'est TEPCO qui en était responsable. C'est en fait la seule façon d'identifier les ouvriers qui sont passés à la centrale jusqu'à cette date. On notait apparemment le numéro de série du dosimètre, le nom de la compagnie de sous-traitance et bien sûr le nom de l'ouvrier.

Une fois contactées, les entreprises pour lesquelles ces ouvriers étaient censés travailler ont affirmé qu'elles n'avaient pas trace de ces gens-là.

Le ministère de la santé trouve que l'administration de TEPCO est du travail de cochon (« sloppy work »)

Au 20 juin il restait 125 ouvriers qui n'avaient pas encore été testés par TEPCO pour mesurer leur taux d'irradiation interne et TEPCO a demandé à certaines entreprises de bien vouloir s'occuper elles-mêmes des tests de 69 ouvriers. C'est à ce moment-là que TEPCO s'est rendu compte que personne ne savait où étaient passés 30 des ouvriers (sur les 69 en question).

La fin de l'article est très bizarre et on dirait qu'il manque quelque chose : il est dit « tous les ouvriers qui n'ont pas été trouvés dans les papiers/registres des entreprises ont rendu leur dosimètre ; leur exposition externe a été enregistrée mais aucun d'eux n'a été exposé à plus de 250 millisieverts (la limite), ont dit les responsables [de TEPCO] »

C'est un heureux hasard ils sont tous gentiment revenus rapporter leur dosimètre à TEPCO et en plus ils ne sont même pas (méchamment) irradiés !

Je me demande ce que tout cela peut vouloir dire. Qui sont ces 30 mystérieux sous-traitants ? Où étaient-ils entre temps (dans une autre centrale ?) et si je comprends bien, ceux-là en tout cas n'ont pas eu droit aux tests pour mesurer leur exposition totale.

France to raise funds for nuclear safety

VIENNA, June 20 | Mon Jun 20, 2011 12:08pm EDT

<http://www.reuters.com/article/2011/06/20/france-nuclear-safety-idUSLDE75J1Q020110620>

(Reuters) - [France](#) will unveil in the next few weeks a substantial rise in research funds for nuclear safety in the aftermath of Japan's nuclear crisis, a ministerial source told Reuters on Monday.

Japan's crisis has prompted a rethink of energy policy worldwide, underlined by Germany's decision to close all its reactors by 2022 and Italy's vote to ban nuclear for decades.

But France, the world's second largest nuclear energy producer after the United States, has not ceased for the past three decades to support nuclear energy even after the 1986 Chernobyl disaster or the [Japan](#) nuclear accident. "It (the decision) will be unveiled within the next two weeks," the source said on the margins of a ministerial conference of the International Atomic Energy Agency.

"This will come, in part, under the form of credits from (France's) big investment plan," the source said.

France has already asked EDF ([EDF.PA](#)), which operates the country's 58 nuclear reactors, to test the reactors' capacity to resist flooding, earthquakes, power outages, failure of the cooling systems, and operation management of accidents.

EDF will have to deliver its report on Sept. 15, which will then have to be examined by the ASN, France's nuclear watchdog.

The U.N. nuclear chief called on Monday for countries to carry out risk assessments on their reactors within 18 months and for strengthened international safety checks to help prevent a repeat of Japan's atomic crisis.

Sacrifices forced on rural sites of nuclear power plants do not bring true wealth

How does the ongoing crisis at the Fukushima No. 1 Nuclear Power Plant appear to those who were once embroiled in disputes over the possible construction of a nuclear power plant in their backyard?

It is predicted that a major earthquake will hit Wakayama Prefecture, where I work, in the near future. Talk of constructing nuclear power plants within the prefecture has emerged numerous times in the past, but thanks to the help of researchers from Kyoto University, such facilities do not exist. The reason for that is simple: **we have no need for dangerous nuclear power plants.**

Most noteworthy of the cases in Wakayama were the protests against plant construction in the town of Hidaka and of Hikigawa, which has since been merged with Shirahama. In Hidaka, the issue had been festering since 1967 when the then mayor revealed his vision for the construction of a nuclear power plant. **In 1988, the Kansai Electric Power Co. (KEPCO) offered the local fisheries cooperative some 700 million yen in compensation for surveys to be conducted in preparation for plant construction.**

Family members and relatives belonging to the cooperative were divided on the appropriate response, leading to opposing sides refusing to attend weddings, funerals, and boat-launching ceremonies. Kazumi Hama, 61, a fisherman who led anti-nuclear plant efforts said that family relationships suffered because of talk of a possible plant.

"If nuclear power plants were safe, we wouldn't have had any infighting. **KEPCO weighed the lives of city dwellers against ours,**" he said.

In Hikigawa, meanwhile, even students on school buses were split into pro-plant and anti-plant sections. According to Tomoaki Nishio, 59, the current head of the town council who was then against the construction of the power plants, **the proposed site for the nuclear power plant had been privately-owned. In 1973, however, the town's land development bureau bought the land, with the promise that it would "make the land into a quasi-national park and protect it from reckless development," and resold it to the municipal government. When town government officials signed a sales contract with KEPCO, a man who had sold his land to the development bureau committed suicide.**

"My father was ashamed that he had been conned by the town government," a 78-year-old bereaved family member said.

The question on the minds of all anti-nuclear plant residents was: **"Why aren't nuclear power plants built in urban areas, where a massive amount of electricity is consumed every day?"** Sharing this

same line of thinking, assistant professors Hiroaki Koide, 61, and Tetsuji Imanaka, 60, of Kyoto University's Research Reactor Institute supported anti-plant protests.

Koide had gone to study at Tohoku University with the belief that nuclear power was going to be the world's future power source. However, he encountered the protests against the construction of Onagawa Nuclear Power Plant in Miyagi Prefecture, and switched over to an anti-nuclear power stand himself.

"Nuclear power plants are dangerous facilities that cities refuse to build within their own borders, which is why they are built in sparsely-populated areas despite the cost of laying down power lines," Koide said. "Once you realize that, there's only one choice. There's no way we can allow such a thing."

Imanaka, too, went to graduate school at Tokyo Institute of Technology with faith in the future of nuclear power, but ended up participating in protests against the construction of the Kashiwazaki-Kariwa Nuclear Power Plant in Niigata Prefecture. He found the power company's claim that nuclear power plants were safe and that they helped local economies dubious. After the Three Mile Island accident in 1979, Imanaka's doubts about nuclear safety turned into conviction about its dangers.

In a lawsuit seeking the reversal of permission given for the construction of Ikata Nuclear Power Plant in Ehime Prefecture, the two researchers served as expert witnesses for the plaintiffs' legal team. They also visited Wakayama on numerous occasions to distribute anti-plant fliers.

Koide's argument is clear-cut: machines sometimes break, and people sometimes make mistakes. It is only natural for nuclear power plants operated by people to break down. When nuclear power plants break down, they cause catastrophes.

As such, the accident in Fukushima was well within the scope of Koide's expectations. And yet, the general public remained under the spell of the "safety myth," and arguments like his went ignored. Koide now blames himself for not having stopped the construction of nuclear power plants, but he also says that **the public is "responsible for being duped."**

The phrase brings to mind the 1946 essay "Senso sekininsha no mondai" (The problem of who is responsible for the war), in which film director Mansaku Itami argued that the general public were partially responsible for the war, for having been "fooled." In the essay, the same man who had penned an extremely compassionate screenplay for the film "Muhomatsu no issho" (Rickshaw man), launched a social critique that cut at the very nature of mankind: "Those who are okay with themselves saying they were 'deceived' will probably be deceived again and again. No, they are surely in the process of being taken in by new lies already."

It is a matter of course that the national government and power companies that went around touting the "safety myth" are criticized. However, we must also hold the public accountable for its part in the disaster by falling for the myth. **The public, through the work of politicians, has distributed millions of yen to rural areas as compensation for the use of their land -- and it is that very distribution system and the safety myth that have forced people to live in danger, alongside nuclear power plants.**

Hama said that there was a time, during the infighting at the fisheries cooperative, that the opposing blocs cooperated to search for a colleague who had gone missing at sea. The body was found a week later.

It was these words from Hama that changed the mind of the Hidaka town mayor, who had been pushing for the construction of the nuclear power plant in their town: "There's a saying that 'for fishermen, hell is one plank away.' Those of us who work under such dangerous conditions have to get along. Hey mayor, do you understand that?"

Does forcing sacrifices upon rural residents and being dependent on nuclear power plants signify true wealth? What we should be aspiring to as a society seems clear enough. (By Takashi Yamashita, Wakayama Bureau)

Temperature at No.3 reactor rises

The operator of the troubled Fukushima Daiichi nuclear power plant says **temperatures at the No.3 reactor have started to rise after it reduced the injection rate of cooling water**. The cutback is part of efforts to prevent possible overflows of radioactive water at the facility.

On Tuesday, Tokyo Electric Power Company reduced the amount of fresh water it has been injecting into 3 of the plant's reactors. The volume was cut back by 0.5 tons per hour at the No. 1 and 2 reactors, and by 1 ton at the No.3 reactor.

TEPCO says that by 5 AM on Wednesday, temperatures at the upper and lower parts of the No.3 reactor had risen by 4 and 7 degrees Celsius, respectively, from the day before. But it says temperatures at the other 2 reactors remained relatively stable.

The company says it will carefully monitor the No.3 reactor but will keep the rate of water injection unchanged. It added that it will further reduce the rate of water injection into the other 2 reactors by 0.5 tons per hour.

TEPCO is facing difficulties in striking a balance between cooling down the reactors and limiting the amount of highly radioactive water threatening to spill out.

More than 110,000 tons of such water is believed to have accumulated at the nuclear complex. Tuesday's start of the annual rainy season has also added to fears of overflows.

TEPCO has yet to start full operation of a crucial system to decontaminate the wastewater. It hopes to use the treated water to cool the reactors.

Wednesday, June 22, 2011 13:04 +0900 (JST)

Hausse des températures dans le réacteur 3

La Compagnie d'électricité de Tokyo, Tepco, a détecté une hausse de la température dans le réacteur 3 de la centrale nucléaire Fukushima Dai-ichi, après avoir réduit le volume d'eau injecté à des fins de refroidissement.

Cette réduction entre dans le cadre des efforts visant à prévenir un débordement d'eau radioactive.

Mardi, l'opérateur a réduit le volume d'eau douce qu'il pompait jusqu'à maintenant dans trois des réacteurs de la centrale.

Tepco a annoncé qu'à 5 heures, ce mercredi matin, la température dans les parties inférieure et supérieure du réacteur 3 avait augmenté de 4 et 7 degrés respectivement, par rapport à la veille.

La compagnie éprouve des difficultés à trouver le juste équilibre entre la nécessité de refroidir les réacteurs et celle de réduire le volume de l'eau contaminée qui menace de déborder.

Le début de la saison des pluies annuelle dans la région, hier mardi, fait craindre encore plus d'éventuels débordements.

Rainy season adds to troubles at Fukushima plant

Tokyo Electric Power Company is stepping up efforts to prevent possible overflows of highly radioactive water building up at the troubled Fukushima Daiichi nuclear plant as the region enters the rainy season.

More than 110,000 tons of highly contaminated water is believed to have accumulated in the basements of reactor and turbine buildings at the plant. The water is increasing by about 500 tons a day, as fresh water must be injected into reactors to cool them down.

The annual rainy season began on Tuesday in the region where the nuclear plant is located, raising concerns that the wastewater could overflow. If 100 millimeters of rain falls over the complex, it may raise water levels in the basements of the turbine buildings by about 50 to 70 millimeters.

TEPCO has been trying to operate a crucial system to decontaminate the highly radioactive water so that it can be recycled to cool the reactors. But as a series of problems has surfaced, it may take 2 more days to finish test runs on the system before full-scale operation.

In an effort to slow down the increase of contaminated water as much as possible, TEPCO decreased water injection into troubled reactors by up to 1.5 tons per hour each from Tuesday.

The company also piled up sandbags around building entrances to prevent rainwater from pouring in. But the measure may have only a limited effect, as some of the buildings had their roofs blown off by explosions.

Wednesday, June 22, 2011 11:23 +0900 (JST)

TEPCO considers new locations for storing contaminated water as overflow threatens

Tokyo Electric Power Co. (TEPCO) **has begun considering new locations for storing contaminated water** from the Fukushima No. 1 Nuclear Power Plant as the water threatens to overflow, the utility announced on June 21.

Furthermore, on June 21 a system being used to treat the contaminated water was halted because of a problem with a French-made pump. The system had been in test operation, and with the new delay **workers are now aiming for a resumption of full-scale operations in two to three days' time.**

The system has had stability problems since it was put into full-scale operation on June 17. A previous problem that occurred with a section of American-made equipment also caused a shutdown.

There are estimated to be over 100,000 cubic meters of contaminated water collected on the plant grounds. With the area having entered the rainy season on June 21, it is feared that the contaminated water could overflow within the month if nothing is done.

TEPCO is checking on the safety of tanks it is setting up to take water with low-level radioactive materials to see if they can store highly radioactive water.

In this May 27, 2011 photo released on June 2, 2011 by Tokyo Electric Power Co. (TEPCO), temporary storage tanks for low-level radioactive polluted waters used for temporary cooling system in Fukushima Dai-ichi nuclear power plant in Okuma, Fukushima prefecture, northeastern Japan, are shown. (AP Photo/Tokyo Electric Power Co.)

"We can't release the contaminated water into the environment," said TEPCO spokesman Junichi Matsumoto at a press conference. "We will take every measure we can."

Goshi Hosono, advisor to Prime Minister Naoto Kan, said, "We have a considerable number of tanks for storing low-concentration contaminated water. We apologize for the worry we have caused to the public. The government will support the response to this problem."

(Mainichi Japan) June 22, 2011

Improper water flow blamed for filter failure

The operator of the Fukushima Daiichi nuclear power plant has resumed testing a water decontamination system after making repairs to improve the flow of the water.

Tokyo Electric Power Company has been testing the system to filter highly radioactive wastewater that has been accumulating at the plant.

The utility discovered on Wednesday that a US-made device in the system only succeeded in lowering the concentration of radioactive cesium in the water to 1 percent of the previous amount, instead of to 0.1 percent as initially expected.

Contaminated water was supposed to pass through 3 absorbent chambers. But it was found that **some water passed through only one chamber, because "open" and "shut" indications on a valve had been incorrect.**

The utility inspected all the valves and resumed test runs early on Thursday.

TEPCO began full-scale operation of the decontamination system last Friday, but it was stopped after only 5 hours.

Thursday, June 23, 2011 12:35 +0900 (JST)

Radioactive dust from Fukushima plant hit N. America soon after meltdown: researchers

A computer simulation-generated map of the diffusion of radioactive materials leaked from the Fukushima No. 1 Nuclear Power Plant. (Image courtesy of the University of Tokyo and Kyushu University)

Radioactive materials spewed out from the crippled Fukushima No. 1 Nuclear Power Plant reached North America **soon after the meltdown and were carried all the way to Europe,** according to a simulation by university researchers.

The computer simulation by researchers at Kyushu University and the University of Tokyo, among other institutions, calculated dispersal of radioactive dust from the Fukushima plant beginning at 9 p.m. on March 14, when radiation levels around the plant spiked.

The team found that radioactive dust was likely caught by the jet stream and carried across the Pacific Ocean, its concentration dropping as it spread. **According to the computer model, radioactive materials at a concentration just one-one hundred millionth of that found around the Fukushima plant hit the west coast of North America three days later, and reached the skies over much of Europe about a week later.**

According to the research team, updrafts in a low-pressure system passing over the disaster-stricken Tohoku region on March 14-15 carried some of the radioactive dust that had collected about 1.5 kilometers above the plant to an altitude of about 5 kilometers. The jet stream then caught the dust and diffused it over the Pacific Ocean and beyond.

The computer model used was designed to simulate the diffusion patterns of yellow sand and air pollution based on real-time weather conditions, and they presupposed particles of radioactive material 10 micrometers -- 0.00001 of a meter -- in diameter.

The simulation results will be published in an upcoming issue of the "Scientific Online Letters on the Atmosphere" (SOLA), an Internet-based publication of the Meteorological Society of Japan.

(Mainichi Japan) June 23, 2011

Work begins inside No.2 reactor building

The operator of the damaged Fukushima nuclear plant reports **considerable lessening of humidity at the Number 2 reactor but radioactivity remains high in some parts of the building.**

Extreme humidity was one of the factors hampering work inside the reactor building. The humidity level stood at 99.9 percent until Sunday when the Tokyo Electric Power Company opened the doors to lower the level after filtering radioactive air inside.

On Wednesday afternoon, workers found humidity levels inside the building to be between 46 and 65 percent.

Following the findings, they began fixing a water gauge and installing surveillance cameras on the ground floor.

High radiation levels were measured at some spots **on the second floor. In one area readings came in at 97.2 millisieverts per hour,** compared 15 to 60 millisieverts per hour on the ground floor.

Wastewater contaminated with nuclear material was 6.1 meters deep in the basement, with surface radiation levels between 388 and 430 millisieverts per hour.

Work on the second floor was scheduled to start on Thursday but was postponed because of the high radiation levels there.

Water treatment system not working as expected

TOKYO (Kyodo) -- Tokyo Electric Power Co. said Wednesday that part of a newly installed radioactive water treatment system at its crippled Fukushima Daiichi nuclear power plant is operating only at 10 percent of its expected decontamination capacity.

The utility said that although the system as a whole is performing above the minimum targeted decontamination level, it is investigating the cause of the insufficiency of a cesium-absorbing device developed by Kurion Inc. of the United States.

During recent trial operations, the installation of the device reduced the level of cesium-134 and cesium-137 in toxic water to one hundredth, although a reduction to one thousandth of the level had been anticipated.

The contaminated water is a side effect of the current emergency step of injecting coolant water from outside, as reactors' cooling functions were lost after the March 11 earthquake and tsunami.

Smooth operation of the system, which is designed to remove highly radioactive materials from a massive amount of water accumulating at the station, is considered essential to containing the three-month-old nuclear crisis, as the utility plans to eventually recycle the water to cool the plant's damaged reactors.

Highlighting the difficulty in containing the water problem, the utility, known as TEPCO, said that possibly toxic water has been found again in the basement of the No. 2 reactor building.

The 6.1 meter-deep water in the basement **may be contaminated due to the effects of damage to the reactor** as radiation doses of 430 millisieverts per hour have been found in the stairs of the building, a TEPCO official said.

(Mainichi Japan) June 23, 2011

Valve likely set incorrectly from the beginning

The operator of the crippled Fukushima nuclear plant says it was unaware of an incorrectly opened valve that caused another disruption in its ongoing test run to filter radioactive water.

Tokyo Electric Power Company found on Wednesday that a US-made device attached to the water treatment system had lowered concentration of radioactive cesium by just 10 percent the planned amount.

The open valve meant that some contaminated water passed through only one of the system's 3 absorbent chambers. The valve is believed to have been incorrectly set since the device was installed.

The amount of contaminated water on site is growing by about 400 tons a day, as fresh water is injected into reactors to cool them. The rainy season threatens to raise the water levels further.

The test-run was interrupted on Tuesday after a pump to send water into French-made decontamination equipment stopped, also due to the wrong setting of a valve.

Thursday, June 23, 2011 19:40 +0900 (JST)

Fukushima Dai-ichi : une valve mal ouverte retarde les tests de filtrage de l'eau contaminée

L'opérateur de la centrale de Fukushima n'était pas conscient du fait qu'une valve mal ouverte était à l'origine d'un nouveau dysfonctionnement du système de filtrage de l'eau radioactive, sur le site.

La Compagnie d'électricité de Tokyo a réalisé mercredi qu'un appareil de fabrication américaine relié au système de traitement de l'eau n'avait permis de réduire la concentration en césium radioactif que de 10 pour cent du résultat escompté.

La valve étant restée partiellement ouverte en raison d'une erreur d'installation, de l'eau contaminée s'est écoulée dans l'une des 3 chambres d'absorption.

Le volume de liquide contaminé augmente chaque jour de 400 tonnes sur le site, de l'eau fraîche étant continuellement injectée dans les réacteurs pour les refroidir. La saison des pluies risque par ailleurs d'empirer la situation.

Checks of Russian nuclear reactors fail safety hopes - and worse, leaked report reveals

http://www.bellona.org/articles/articles_2011/rosatom_report

A report stunning in its candor prepared for Russian President Dmitry Medvedev by the country's state nuclear monopoly in the wake of Japan's Fukushima disaster reveals that Russia's atomic reactors are grievously under-prepared for both natural and man-made disasters ranging from floods to fires to earthquakes or plain negligence. [Charles Digges, Maria Kaminskaya, 21/06-2011](#)

[The report of the first round of stress tests on Russia's nuclear reactors](#), prepared by Russian state nuclear corporation Rosatom, was obtained by Bellona Web and other environmental groups and distributed to Norwegian and Russian media.

The report comes as several countries have given up on hopes of a nuclear future. Germany had voted to phase out its last nuclear power plant by 2022, and Switzerland plans to follow suit by 2035. Last week, Italy sent a strong message in a referendum when 95 percent of Italian voters turned down the

opportunity to have a future lighted by nuclear power. Russians have similarly expressed in polls, that they would like to see Russia pursue a different energy strategy.

The Rosatom report would seem to indicate that as the only reasonable alternative. In it, 31 serious flaws that make Russia's nuclear industry extremely vulnerable to natural disasters are catalogued.

As such, the report is one of the few documents to surface in recent history that actually flatly contradicts Russia's own rosy assessment that its reactors are safe – a propaganda campaign that was kicked into high gear by Prime Minister Vladimir Putin and President Medvedev after the March 11 quake and tsunami hit Fukushima Daiichi, causing three meltdowns.

Bellona nuclear physicist Nils Böhmer called the Rosatom report “shocking.”

“It makes for dramatic reading with a view to the fact that the report comes from the owner of the nuclear plants,” he said, describing it as “the most serious description of the status of Russian nuclear plants I have ever seen from Rosatom.”

Report confirms long-held fears

The two Russian nuclear power plants that are closest to Finland and Norway – Leningrad Nuclear Power Plant (NPP) and Kola NPP, respectively – are of the most concern to the international community. Both are in close proximity to Western Europe.

“The report reveals deficiencies which have never before been mentioned publicly, nor reported internationally,” chief engineer Ole Reistad of the Norwegian Institute for Energy Technology (IFI) told Norway's NRK television.

Of particular concern at the Leningrad NPP (LNPP) is its use of the fatally flawed Chernobyl-type RMBK-1000 reactors. LNPP operates four RMBK-1000s, while the Kola NPP runs four aged VVER-440 reactors, two of which received engineering life span extensions in 2003 and 2004.

The Rosatom report, stating what many have asserted since Chernobyl, detailed “flaws and defects” in the design of the RMBK-1000 series that could lead to severe accidents - specifically, problems with control rod mechanisms, which are necessary to keep the nuclear reaction in the reactor under control.

The report's revelations have alarmed the government of Norway. Norwegian State Secretary Erik Lahnstein of the Foreign Ministry, who received an overview of the report, told Aftenposten he wanted a full copy of the report sent to the International Atomic Energy Agency, saying “this confirms what Norwegian authorities have claimed for a long time.”

He stressed that Russia should shut down its oldest reactors. The Rosatom document said four reactors have been in shutdown mode for 20 years, and no decommissioning plans have yet been set in motion. This would arguably present difficulties in decommissioning other aged reactors in Russia.

Ole Harbitz, head of the crisis commission for the Norwegian Radiation Protection Authority, said of the report that it showed Russia was rethinking the vulnerability of its nuclear reactors to natural phenomena in the post-Fukushima era.

The dangers have been proven before: In the 1990s a severe storm knocked out primary and back-up power supplies to Kola NPP and Norway had to deliver enormous power generators to keep coolant flowing. In 2006, another power outage threatened coolant systems at the plutonium reactor at the Mayak Chemical Combine.

In Finland, Keijo Valtonen, an official at the Radiation and Nuclear Safety Authority Finland (STUK) somewhat soft-pedalled the dangers posed by Russia's reactors, particularly those at Kola and Leningrad NPPs.

Valtonen told Helsingin Sanomat that most of Russia's nuclear plants meet Western safety standards, but that new threats might arise in inspections made after the catastrophe at Fukushima.

But Valtonen has an agenda of his own: By some estimates, some 30 to 40 percent of power produced at Leningrad NPP is exported to Finland, and annual inspections of the plant by representatives of STUK consistently give it high marks, despite environmental dangers that are regularly revealed and confirmed there.

What the report said

Among the more critical safety failings relayed to Medvedev in the report, Rosatom found that Russia's plants do not have relevant regulations in place for personnel to know how to deal with large-scale natural disasters or other serious contingencies; protective shelter for workers would not accommodate the largest teams on any given shift in the event of an accident, and Rosatom does not keep records of previous accidents, meaning workers do not have the benefit of learning from previous mistakes or improving remedial measures, among other shortcomings.

Elsewhere in the report, Rosatom points out that electrical and safety-significant systems do not receive the attention they need, resulting in a lack of required protection.

The Rosatom document also questioned the capability of reactors to remain safe for extended periods of time if cooling systems fail. There is no guarantee that power backup systems will be effective should this happen - the primary difficulty that beset Fukushima Daiichi when the quake and tsunami hit.

Additionally, key equipment involved in the cooling process suffers from metal fatigue and welding flaws – yet another problem that was ignored at Fukushima Daiichi's reactor No 1 when regulators there agreed to give it a 10-year operational life span extension – which contributed to a total failure of cooling at the reactor.

Hydrogen control systems also do not correspond to regulations, meaning Russian reactors are vulnerable to the kinds of hydrogen explosions that tore through three reactor buildings at Fukushima Daiichi.

Most importantly, in light of the Fukushima disaster, the report also said that the risk of earthquakes has not been considered as a safety factor for Russian nuclear facilities. Furthermore, not all of Russia's reactors have automatic shutdown mechanisms like the Fukushima Daiichi plant, should an earthquake occur.

Nor are there currently clear guidelines or sufficient infrastructure for spent nuclear fuel (SNF) management, leading to fears of SNF leaks during a disaster – as also happened in Japan. With respect to Russia’s RBMK-1000 reactors, spent fuel is simply allowed to accrue in onsite storage because of lack of space to store it and because no technologies have been developed to reprocess it. Solid and liquid waste facilities across Russia are filled to at least 60 percent, and these facilities at Leningrad, Kursk and Smolensk NPPs – all of which run RBMK 100 reactors – are filled to 85 percent capacity.

Reactor buildings at many of Russia’s nuclear power plants are also aged and susceptible to structural failure - meaning the buildings could collapse without the help of mother nature.

Further, the Federal Service for Environmental, Technological and Nuclear oversight, or Rostekhnadzor – Russia’s nuclear industry watchdog – lacks safety inspectors, and there is a shortage of qualified maintenance workers at NPPs across the country.

Rosatom Chief Sergei Kiriyenko was quick to comment on the report once Norwegian news outlets and Russian environmentalists had publicized its findings, saying it was just a matter of money to fix Russia’s shortcomings in the area of back-up power and coolant system deficiencies.

In the Vedomosti business daily, he cited a figure of 5 billion rubles (\$986 million) to bring Russia’s reactors up to specifications by enhancing their back-up power and coolant systems. To counter cost overruns, Kiriyenko told the paper, Rosatom would rely on the government.

Choking on earlier words

Vladimir Sliviyak, co-chair of Russia’s Ecodefence – one of the first Russian environmental groups to get hold of the report – was quick to point out the contrast between the Russian government’s initial statements that what had happened at Fukushima could never be repeated in Russia with the report, which says that it could.

“Soon after March 11, Premier Putin ordered a check of Russias nuclear power plants. Later the announcement was heard that all reactors had been checked and Fukushima will not be repeated here,” wrote Sliviyak in his [June 9 blog for Ekho Moskvyy radio](#) (in Russian).

“No information that would allow the confirmation or refutation of these conclusions was released,” he wrote.

“So what did we get as a result?” continued Sliviyak. “That the announcements of authorities at different levels – all the way to the prime minister – that the checks carried out after the Fukushima crisis revealed that Russia’s nuclear power plants were completely safe is a complete fantasy.”

TEPCO working to prevent overflow of toxic water

The operator of the Fukushima Daiichi nuclear plant is striving to prevent highly radioactive water from overflowing the facility amid delays in restarting a key water decontamination system.

Tokyo Electric Power Company has been reducing the volume of water injected into the first 3 reactors

since Tuesday to curb a further build-up of highly radioactive water at the plant.

On Friday, it further reduced the volume of water injected into the No.3 reactor by 0.5 tons to 9 tons per hour.

But limiting the amount of water could allow the temperature of the reactors to rise.

To aggravate the situation, rain is continuing to fall in the area where the power plant is located.

Last month, accumulated rainfall of 100 millimeters pushed up the water levels by around 50 to 60 millimeters.

TEPCO is plugging holes in the roofs of the turbine buildings and stacking sandbags to prevent rain water from entering the facility.

The power company is continuing test runs of the decontamination system to work out ways to ensure its optimal operation.

It says it has so far processed around 2,500 tons of radioactive water with the system. On Friday, it began work to desalinate treated water with the aim of recycling it to cool down the overheating reactors.

Friday, June 24, 2011 12:51 +0900 (JST)

High level of radiation exposure estimated

A group of doctors has found that the estimated level of accumulated internal radiation exposure for people living in Fukushima Prefecture has exceeded 3 millisieverts.

The researchers, including doctors who have provided medical care to A-bomb survivors, conducted analysis on the food and urine of 15 residents in Iitate Village and Kawamata Town in Fukushima Prefecture. These areas are about 40 kilometers from the Fukushima Daiichi nuclear power plant.

They estimate that residents have been internally exposed to up to 3.2 millisieverts for about 2 months, measuring from the date of the accident in March until early May.

Three millisieverts is 3 times higher than the long-term annual limit for ordinary people recommended by the International Commission on Radiological Protection.

One of the researchers, Nanao Kamada, says people should refrain from eating vegetables grown in the area where high levels of radiation have been detected.

Friday, June 24, 2011 07:00 +0900 (JST)

De hauts niveaux de radiation estimés dans la préfecture de Fukushima

Des chercheurs estiment que des habitants de la préfecture de Fukushima ont subi une exposition interne aux radiations supérieure à 3 millisieverts.

Les scientifiques, dont des médecins ayant soigné des survivants des bombardements atomiques, ont effectué une étude auprès de 15 habitants du village de Iitate et de la ville de Kawamata, qui se trouvent à une quarantaine de km de la centrale nucléaire Fukushima Dai-ichi.

Ils ont étudié l'alimentation et les urines et estiment que l'exposition interne des habitants a atteint 3,2 millisieverts entre le jour de l'accident et début mai, soit pendant deux mois environ.

Or 3 millisieverts représentent trois fois le niveau maximum de contamination annuelle recommandé par la Commission internationale de protection radiologique.

Efforts à Fukushima contre le risque d'inondation

La Compagnie d'électricité de Tokyo, Tepco, s'efforce d'empêcher l'eau hautement radioactive d'inonder la centrale nucléaire de Fukushima.

Alors que le redémarrage de l'installation de décontamination de l'eau radioactive prend du retard, Tepco a décidé dès mardi de réduire les injections d'eau dans les réacteurs 1, 2 et 3, avec pour objectif de limiter l'accumulation de l'eau dans la centrale.

Vendredi, la compagnie a à nouveau réduit les injections d'eau dans le réacteur numéro 3, de 0,5 tonne à 9 tonnes par heure. Mais la baisse des injections d'eau pourrait se traduire par une hausse des températures.

La situation est compliquée par la pluie qui continue de tomber sur la région. Tepco s'efforce de boucher les trous des toits des bâtiments abritant les turbines et entasse des sacs de sable pour empêcher la pluie d'entrer dans les installations.

On soupçonne maintenant fortement que TEPCO n'a jamais en fait ventilé le réacteur no1 le 12 mars pour faire baisser la pression et éviter l'accident, comme ils l'avaient pourtant affirmé (disant qu'ils avaient réussi)

Le gouvernement a repris cette affirmation, SANS en VERIFIER (durant 3 mois) la véracité.

TEPCO dit maintenant qu'ils ne peuvent pas confirmer avoir réussi ou non à ventiler non seulement le réacteur 1, mais le réacteur 2 également !!

Tout ceci soulève, conclut l'article, des questions quant aux mesures de sécurité prises par les agences de régulation gouvernementales à propos des centrales nucléaires. [\[ah bon ?\]](#)

Suspected failure to vent Fukushima reactor casts doubt on accountability standards

The No. 1 reactor building at the Fukushima No. 1 Nuclear Power Plant is seen from the air in this April 10 file photo provided by TEPCO.

Revelations that Tokyo Electric Power Co. (TEPCO) highly likely failed to vent a crippled reactor at its tsunami-hit Fukushima No. 1 Nuclear Power Plant have raised doubts about the utility's and government's accountability standards.

TEPCO had claimed that it had successfully vented the plant's No. 1 reactor to decrease pressure inside it prior to a hydrogen explosion, and the government had supported the power supplier's claim.

The power company attempted to vent the reactor on March 12, the day after the tsunami triggered by the Great East Japan Earthquake hit the plant. After confirming that the pressure inside the containment vessel of the reactor had declined, TEPCO announced at around 3 p.m. that it had succeeded in venting the reactor.

However, the pressure still remained above the designated upper limit of 427 kilopascals and rose moderately after the announcement. Moreover, the monitoring post on its premises showed no signs of radioactive materials being released out of the reactor following the venting attempt. TEPCO insiders say they were unable to confirm that the valve for venting had opened.

Both TEPCO and the government could have checked whether the venting was successful on many occasions. Nevertheless, the government simply mimicked TEPCO's comments on the matter in a report it submitted to the International Atomic Energy Agency (IAEA) on June 7, **without scrutinizing the utility's view for nearly three months.**

In 1992, the International Trade and Industry Ministry (the predecessor of the Ministry of Economy, Trade and Industry) urged power suppliers to equip all reactors at their nuclear power plants with valves and other venting devices as part of their accident management efforts.

TEPCO increased the pressure capacity of the reactors at the Fukushima No. 1 plant and finished equipping them with valves for venting by 2001.

However, the power company has now admitted that it cannot confirm whether it was successful in venting not only its No. 1 reactor but also its No. 2 reactor.

The apparent failure to vent the reactor, which the government viewed as an effective way to respond to a serious nuclear power accident, has raised **questions about government regulatory bodies' safety measures for nuclear power plants.**

The government's fact-finding panel is urged to closely scrutinize whether the utility was sufficiently prepared for a possible serious accident at its nuclear power stations as well, as it assumed that the plant could be hit by a massive tsunami like the one triggered by the March 11 quake. (By Naritake Machida and Shusaku Sugimoto, Tokyo City News Department)

(Mainichi Japan) June 24, 2011

TEPCO likely failed to vent No. 1 reactor at tsunami-hit nuclear plant

This Sunday, April 10 image taken by T-Hawk drone aircraft and released by Tokyo Electric Power Co. (TEPCO) shows the damaged reactor building of Unit 1 of the tsunami-crippled Fukushima Dai-ichi nuclear power plant in Okuma town, Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

Tokyo Electric Power Co. (TEPCO) likely failed in its attempt to vent the No. 1 reactor of its tsunami-hit Fukushima No. 1 Nuclear Power Plant in mid-March shortly before a hydrogen explosion, despite its claim that it successfully vented the reactor, it has emerged.

TEPCO insiders said the valves for venting the reactor did not sufficiently open, and TEPCO's headquarters admitted that it has not confirmed whether the valves opened.

Experts have pointed out that data released by the utility suggests that one of the valves closed after it briefly opened. However, it still remains unclear whether the hydrogen explosion in the reactor building was caused by a venting failure, as experts say it is possible that hydrogen was accumulating even before the venting attempt.

Shortly after noon on March 12, the pressure inside the containment vessel in the plant's No. 1 reactor surged to 600 kilopascals -- far above the upper designated limit of 427 kilopascals -- prompting the plant manager to instruct workers to vent the reactor building.

At 6:50 a.m., the government ordered TEPCO to vent the reactor building under the Act on the Regulation of Nuclear Source Material, Nuclear Fuel Material and Reactors. Plant workers began to vent the reactor at around 9 a.m.

In venting a reactor, steam and hydrogen in its containment vessel are sent through pipes from the suppression pool at the bottom of the vessel. This passes through the AO valve unit that is driven by air on the basement of the reactor building and the MO valve on the second floor that is driven by electric power, before being released out of the building through a duct.

This Sunday, April 10 image taken by T-Hawk drone aircraft and released by Tokyo Electric Power Co. (TEPCO) shows reactor buildings of Unit 2, left, and Unit 1, right, of the tsunami-crippled Fukushima Dai-ichi nuclear power plant in Okuma town, Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

The AO valve unit consists of a small valve and a big valve, and if one of them functions, steam can be led into the duct.

TEPCO workers operated the emergency lever to manually open the MO valve by 25 percent at around 9:15 a.m. About 15 minutes later, they attempted to manually open the small valve in the AO unit, but abandoned it because radiation levels around the unit were extremely high. At 10:17 a.m., the workers tried to open the small valve by remote control from the central control room.

More than 10 minutes afterward, radiation levels outside the No. 1 reactor building rose sharply, indicating that radioactive substances were being released from the structure. However, the levels returned to normal just 30 minutes later.

The pressure inside the containment vessel failed to decline, and TEPCO was unable to confirm whether its attempt to vent the reactor was effective.

At around 2 p.m., TEPCO used an air compressor borrowed from another company to send compressed air into the big valve in an attempt to open it.

The pressure inside the containment vessel subsequently decreased from 755 kilopascals recorded shortly before the work commenced to 530 kilopascals.

TEPCO then announced at around 3 p.m. that it had reached the conclusion that the reactor had been successfully vented at 2:30 p.m., a view that the Nuclear and Industrial Safety Agency (NISA) supported.

This satellite image provided by DigitalGlobe shows the damaged Fukushima Dai-ichi nuclear facility in Japan on Monday, March 14, 2011. Authorities are struggling to prevent the catastrophic release of radiation in the area devastated by a tsunami. (AP Photo/DigitalGlobe)

However, TEPCO insiders have admitted that the valves were not sufficiently opened. Specifically, the air compressor did not sufficiently compress the air to fully open the big valve, according to the insiders. Moreover, an indicator in the reactor did not show that the valves had opened.

The pressure inside the containment vessels stopped decreasing at around 3 p.m. and then continued to rise until the hydrogen explosion occurred at 3:36 p.m.

"We concluded that we successfully vented the reactor because the pressure inside its containment vessel declined. We haven't confirmed whether the big valve opened," a TEPCO official said.

NISA denied that it had determined TEPCO was successful in venting the reactor.

"It was TEPCO that judged that it had successfully vented the reactor, but the government hasn't mentioned whether the attempt was successful," a NISA representative said.

In a report submitted to the International Atomic Energy Agency, the government clearly stated that TEPCO had concluded that it was successful in venting the reactor, which is expected to stir controversy during discussions of the government's fact-finding panel.

Decontamination system meets performance target

The operator of the Fukushima Daiichi nuclear plant says a trouble-hit system for decontaminating highly radioactive water at the facility **is working as planned**.

The Tokyo Electric Power Company, or TEPCO, said on Friday that the system can reduce the density of radioactive substances in the water to the targeted level of one-100,000th.

The system is seen as the key to reducing the amount of contaminated water threatening to overflow from the plant's compound.

TEPCO said a US-made device for absorbing radioactive cesium continues to perform at one-tenth its

intended capacity, even after workers readjusted a faulty valve setting.

But the firm says test runs have shown that the targeted level can be achieved when the device is used with a French decontaminator.

TEPCO says about 2,500 tons of radioactive water has been decontaminated so far. On Friday, workers began sending the water through salt-removing equipment.

The firm plans to return the treated water to reactors this month, to establish a stable cooling system that involves circulating the water.

But TEPCO says resuming full operation of the decontamination system may take several more days.

Friday, June 24, 2011 19:59 +0900 (JST)

Radiation results in Fukushima City

Radiation levels in parts of Fukushima City, about 60 kilometers from the disaster-stricken nuclear plant, have been found to require further monitoring.

Responding to residents' demands for more information, Fukushima City released on Friday the results of radiation checks conducted on June 17th and 20th at more than 1,000 sites, including public facilities and roads in residential areas.

Six locations, including a park in a municipal housing complex, registered radiation levels of over 3.4 microsieverts per hour when measured one meter above ground. This exceeds the prefecture's threshold for re-checking.

Radiation of over two microsieverts per hour was recorded at 182 sites.

The city said that it re-checked the six sites on Friday, and all locations registered lower radiation.

But the city intends to restrict use of the park in the public housing complex, where radiation of 4.15 microsieverts per hour, which exceeds the central government's limit of 3.8 microsieverts for a park, was recorded 50 centimeters above the ground.

A municipal official says the city will continue monitoring and post the results on its website.

Friday, June 24, 2011 21:05 +0900 (JST)

Water treatment system at Fukushima plant achieves decontamination

In this June 1, 2011 file photo released by Tokyo Electric Power Co. (TEPCO), workers inspect equipment inside the cesium absorption tower, part of the radioactive water processing facilities at the Fukushima No. 1 Nuclear Power Plant in Okuma, Fukushima Prefecture. (AP Photo/TEPCO)

TOKYO (Kyodo) -- The glitch-plagued water decontamination system at the Fukushima Daiichi nuclear power complex has been able to lower the concentration of radioactive substances in highly contaminated water to the targeted level, the plant's operator Tokyo Electric Power Co. said Friday.

The successful trial run of the water treatment system paves the way for the start, possibly by the end of June, of operations to cool the damaged nuclear power reactors using water recycled in the decontamination system to establish a circulating cooling system as part of efforts to contain the crisis triggered by the earthquake and tsunami in March.

The utility known as TEPCO said the level of both radioactive cesium-134 and cesium-137 in the toxic water had dropped to one hundred-thousandth, achieving the target of 100 becquerels per cubic centimeter or less.

In this May 10, 2011 file photo released by Tokyo Electric Power Co., workers check the status of the water level indicator at the Unit 1 reactor building at the Fukushima Dai-ichi nuclear power plant in Okuma town, Fukushima Prefecture, northeastern Japan.(AP Photo/Tokyo Electric Power Co.)

The treated water was sent to a desalination device which TEPCO started operating Friday.

The decontamination system comprising equipment from France's Areva SA and Kurion Inc. of the United States is designed to remove radioactive materials from massive amounts of highly contaminated water accumulating at the power station.

The contaminated water, which includes leaking coolant liquid injected from outside, has prevented TEPCO from starting work to restore the reactors' cooling functions.

TEPCO, meanwhile, suspended its operation using a robot to install a water gauge in the basement of the plant's No. 2 reactor to monitor the depth of highly contaminated water accumulating there.

In this June 9, 2011 image taken from a video and released by Tokyo Electric Power Co. on Wednesday, June 15, 2011, workers are seen as they measure radiation dosage inside the Unit 3 reactor building of the Fukushima Dai-ichi nuclear plant in Okuma, Fukushima prefecture, northern Japan. (AP Photo/Tokyo Electric Power Co.)

The Japanese-made robot called "Quince" could not reel out a cable attached to the water gauge, and the path to the basement was too narrow for the remote-controlled machine to maneuver, TEPCO said.

(Mainichi Japan) June 25, 2011

News Navigator: Are there final disposal facilities for radioactive waste?

In this March 24, 2011 file aerial photo taken by a small unmanned drone and released by AIR PHOTO SERVICE, damaged Unit 4 of the crippled Fukushima Dai-ichi nuclear power plant is seen in Okumamachi, Fukushima prefecture, northern Japan. (AP Photo/AIR PHOTO SERVICE)

The Mainichi answers some common questions readers may have about nuclear waste disposal in the wake of the crisis at the Fukushima No. 1 Nuclear Power Plant.

Question: Where does the radioactive waste created by nuclear power plants come from?

Answer: At nuclear power plants, the radioactive material uranium undergoes nuclear fission, providing energy. The product left over after this process is referred to as "spent nuclear fuel." Japan is promoting a nuclear fuel cycle in which uranium and plutonium are extracted from this spent fuel and reused, but high-level radioactive material that can't be reused is left behind as radioactive waste.

Q: How much of this radioactive waste is produced?

A: In Japan there are about 1,700 rods of nuclear waste stored at Rokkasho, Aomori Prefecture, and Tokai, Ibaraki Prefecture. The rods, each of which stand about 130 centimeters tall and weigh some 500 kilograms, are made by mixing spent nuclear fuel with melted glass. Under government estimates there will be roughly 40,000 of these rods in Japan by about 2021.

In this undated photo released Wednesday, April 13, 2011 by Tokyo Electric Power Co., a standing man is partially seen above an example of the truck used to move spent fuel rods in the pools. Nothing is decided yet but TEPCO told the press at its Tokyo headquarters Wednesday morning that this is one option TEPCO officials are considering to use at the tsunami-stricken Fukushima Dai-ichi nuclear power plant in Okuma town in Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

Q: How does Japan plan to dispose of these 40,000 rods?

A: Japan has decided to build a final disposal facility for high-level radioactive waste, enclose the glass rods in steel containers and bury them at least 300 meters below the ground. The rods emit strong radiation, and it is said that it would take tens of thousands of years for this radiation to fall to a level matching that of natural uranium deposits.

Q: That's a long time. So where is this final disposal facility?

A: So far, there are still no permanent repositories in the world for high-level radioactive waste, though Finland and Sweden have finalized building locations. In Japan, an organization authorized by the Ministry of Economy, Trade and Industry has from December 2002 been publicly seeking local bodies willing to host a final repository. By simply signing up for an initial survey into building a site, a local body could receive as much as 2 billion yen in subsidies. In January 2007 the Kochi Prefecture town of Toyo became the first municipality to apply, but the town assembly and residents opposed the project, and the mayor who was later elected withdrew the application.

Q: The government is asking that nuclear reactors not in operation be restarted, but at its current pace, Japan will one day end up with more nuclear waste than it can handle, won't it?

In this image released Saturday, April 16, 2011, by Tokyo Electric Power Co., top of the container of the nuclear reactor, painted in yellow, of Unit 4 at the Fukushima Dai-ichi Nuclear Plant is observed from its side with a T-Hawk drone Friday, April 15, 2011 in Okuma, Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

A: Japan has 54 nuclear reactors, the third most of any country in the world. Since the outbreak of the nuclear crisis in Fukushima Prefecture, countries in Europe and other places have moved to phase out nuclear power, but they cannot avoid the problem of settling on a final disposal facility for radioactive waste that they have already produced. All of us who have enjoyed a stable source of electricity from nuclear power must think about this issue and discuss it in greater depth. (Answers by Takayuki Hakamada, City News Writer)

(Mainichi Japan) June 25, 2011

TEPCO n'arrive toujours pas à évaluer le niveau d'eau dans le réacteur no.2

Une nouvelle jauge a été installée pour mesurer le niveau d'eau et la pression du réacteur mais elle ne marche pas correctement.

Selon TEPCO la raison en est que la température près de l'enceinte de confinement du réacteur est si élevée que l'eau à l'intérieur des tuyaux (de la nouvelle jauge, si je comprends correctement) s'est évaporée.

On peut présumer en effet que comme il y a eu fusion du cœur des réacteurs (1, 2 et 3) il est fort possible qu'il reste peu d'eau à l'intérieur du réacteur no.2.

Des mesures précises du niveau d'eau sont essentielles pour garantir la stabilité du refroidissement du réacteur.

TEPCO unable to gauge No.2 reactor water level

The operator of the crippled Fukushima Daiichi nuclear power plant says it still cannot obtain accurate data on the water level and pressure of the Number 2 reactor. It says a provisional measuring device installed earlier this week is not operating properly.

Tokyo Electric Power Company believes that readings by the original device are incorrect due to damage suffered in the March disaster.

Workers at the utility company entered the Number 2 reactor building and installed the provisional gauge on Wednesday. The company initially planned to have the gauge begin providing data on Thursday.

But it says as of Saturday, **the device is not yet working properly.**

TEPCO says this is because the temperature near the reactor containment vessel is so high that water inside the device's pipes has evaporated.

Fuel meltdowns are believed to have occurred at the Number 1 through Number 3 reactors, leading to a possibility that there is little water left inside the Number 2 reactor.

Accurate measurement of the water level is essential for ensuring stable cooling of the reactor.

The utility is struggling to find ways to activate the device.

Saturday, June 25, 2011 13:21 +0900 (JST)

Reports on Fukushima reactors made public

Japan's Nuclear and Industrial Safety Agency has made public on its website documents revealing what happened at the Fukushima Daiichi nuclear power plant after the March 11th earthquake and tsunami.

The agency on Friday posted on its website Tokyo Electric Power Company's reports, which were submitted to the agency between March 11th and May 31st. The documents totaled 11,000 pages.

It says the government used these documents as reference material when it compiled a report on the nuclear crisis, which was submitted earlier this month to the International Atomic Energy Agency.

Documents submitted to the government were handwritten up to March 19th, during which the Fukushima Daiichi plant was left without electricity.

Goshi Hosono, the prime minister's advisor on the Fukushima accident, spoke about the documents in a news conference on Friday.

He said he has insisted on their release since they include an account of how the plant operator came to use seawater to cool down reactors.

Hosono also said their release was delayed due to the volume of the reports.

The agency says documents submitted after June 1st will also be made available on its website.

Saturday, June 25, 2011 08:56 +0900 (JST)

Des rapports sur la centrale de Fukushima rendus publics

L'Agence de sûreté nucléaire et industrielle du Japon a publié sur son site internet des documents révélant ce qui s'est passé à la centrale nucléaire Fukushima Dai-ichi à la suite de la double catastrophe du 11 mars.

L'agence a ce vendredi mis en ligne sur sa page internet des rapports qui avaient été rendus entre le 11 mars et le 31 mai par la Compagnie d'électricité de Tokyo, Tepco. Ces documents comptent au total 11 000 pages.

Les rapports soumis au gouvernement ont été écrits à la main jusqu'au 19 mars, période pendant laquelle la centrale Fukushima Dai-ichi avait été privée d'électricité.

L'agence indique que les documents qui ont été soumis après le 1er juin seront eux aussi disponibles sur son site internet.

OPINION: Nuclear power requires perfection

By Jonathan Schell
WASHINGTON, June 24, Kyodo

It has been three months since the Fukushima nuclear power disaster, and a clear global consequence is emerging.

The "nuclear renaissance" that supposedly was getting under way before the accident looks as though it has been stopped, and the world may even have begun the long process of getting out of the nuclear power business altogether.

In Japan, of course, all of nuclear power is under review, and Prime Minister Naoto Kan has had to assure the country that he will step down after the Fukushima crisis is over.

In Italy, the people have voted down nuclear power. The Swiss parliament has set the same course. Germany will phase out nuclear power altogether.

The German case is of special historical importance. In 1938, the chemist Otto Hahn first split uranium atoms, releasing the energy in them, making possible both nuclear power and nuclear bombs.

In this respect, the nuclear age began in Germany. Will it also end there?

However that may be, it is interesting to inquire how this result is being reached. The basic answer is not that governments have reconsidered. Ordinary people have.

The reversal in the German policy came after the ruling party suffered defeats in local elections. In Italy, it was the voting public that vetoed the government's plans.

Ordinary people are not nuclear experts. But they know some things that many experts prefer to forget. They know that even in the best-run enterprises, things go awry.

The contractor takes a kickback. The operator at the control panel falls asleep. The battery runs out sooner than expected. The scientist shades his findings because he has received a grant from the industry under inspection.

All this forms the inescapable background when the big, rare challenges arise: the earthquake, the tsunami, the airliner crash into the containment structures.

Of course the people in charge come up with new, improved safety plans -- more batteries, more generators, thicker containment walls, more security guards.

But the truth known to ordinary people is that these are subject to the same ineradicable human foibles as the old safety plans. When the stakes are a cost overrun on a factory or heavier taxes or potholes in a highway, everyone eventually accepts the cost and moves on.

But when the cost could be six nuclear reactors belching radiation wherever the winds have to carry it, rendering large territories uninhabitable, the cost is too high.

Nuclear power requires perfection. But human life is a scene of error and turmoil. The problem is not a broken valve or an inadequate flood wall or even the earthquake or tsunami.

It is the fundamental mismatch between fallible human beings and a universal power that is too great for us to control. That is what Fukushima teaches and that is what the world is learning.

(Jonathan Schell, born in New York in 1943, is known as a journalist who has had influence on antinuclear movements in the United States. He has written books such as "The Fate of the Earth" and "The Gift of Time.")

==Kyodo

en gros(voir ci-dessous) TEPCO n'a pas remis en route les opérations de décontamination.

Pendant ce temps ils continuent à injecter de l'eau dans les réacteurs **de façon continue**

Pour l'instant ils ont nettoyé 4 500 tons d'eau contaminée (sur ????)

Et maintenant on apprend que l'eau contaminée voyage sur ... 4 kilomètres durant le traitement. Ce qui signifie un certain nombre de tuyaux et de valves à vérifier "sérieusement" !! Les divers éléments du système de décontamination sont en effet situés dans différents endroits de la centrale.

Resumption of decontamination system not in sight

The operator of the troubled Fukushima Daiichi nuclear power plant **has still not resumed operations of a system to decontaminate highly radioactive water.**

Tokyo Electric Power Company had planned to start decontaminating and recycling the water by July 17th to cool the reactors.

Water is being injected continuously into the reactors and the resulting contaminated water is starting to fill up the storage facilities, raising fears that it will start overflowing around July 5th.

So far 4,500 tons of contaminated water has been treated in a test run, and work to remove salt started on Friday.

The company says the amount of stored contaminated water will drop significantly, once the decontamination system begins operating. It says it wants to start spraying the recycled water into the reactors by the end of this month.

But first, pipes and valves must be checked thoroughly as the components of the system are located in different parts of the plant, and the contaminated water travels a distance of 4 kilometers during treatment.

Tokyo Electric Power Company hopes to fully restart the decontamination system in the next few days. But it has experienced a number of problems and it is unclear whether the recycling of water can be carried out as planned.

Saturday, June 25, 2011 22:05 +0900 (JST)

Tepco se dit prête à injecter de l'azote dans le réacteur 2

La Compagnie d'électricité de Tokyo, Tepco, se prépare à injecter de l'azote dans l'enceinte de confinement du réacteur 2 de la centrale nucléaire Fukushima Dai-ichi dans le but de prévenir des explosions d'hydrogène.

La compagnie a déclaré qu'elle surveillera plus attentivement les niveaux de radiation autour du

complexe, car l'azote pourrait provoquer de légères émissions de gaz contenant des substances radioactives.

Les opérations de décontamination de l'eau suivent leur cours dans la centrale nucléaire endommagée. L'eau devrait être réinjectée dans les réacteurs pour les refroidir.

Cependant, si les réacteurs sont refroidis à un niveau stable, il y aura moins d'humidité émise, augmentant ainsi la proportion d'hydrogène dans l'air.

Il y a des risques d'explosion quand l'hydrogène est en contact avec l'oxygène.

TEPCO injecte de l'azote dans le réacteur 1 depuis le mois d'avril et vient de finaliser les préparatifs pour faire de même dans le réacteur 2.

Elle prévoit le début de l'opération d'injection dès qu'elle aura obtenu l'accord de l'Agence de sûreté nucléaire et industrielle.

l'eau de la piscine de combustible usé du réacteur 3 était devenue alcaline (PH 11,2) sans doute à cause des décombres qui étaient tombés dedans lors de l'explosion de mars. Ce qui pourrait accélérer la corrosion des racks en alu qui portent les barres de combustible. Bref TEPCO craint que le tout ne puisse s'écrouler, ce qui pourrait amener à un pb de "re-criticalité".

Mais tout cela n'est pas grave, car en juillet, début juillet même, on aura un beau système de refroidissement pour la piscine....

Boric acid being added to No.3 reactor fuel pool

Tokyo Electric Power Company has begun adding boric acid to the spent fuel storage pool of the No.3 reactor at its Fukushima Daiichi nuclear plant to prevent fuel racks from being corroded by alkaline water.

The company started the operation on Sunday morning. About 90 tons of water containing boric acid will be poured into the pool through Monday.

Concrete debris from the March hydrogen explosion of the reactor building has been detected in the fuel pool.

Last month, TEPCO found that the water in the pool had turned strongly alkaline, with its PH level reaching 11.2. The leaching of calcium hydrate from the debris is believed to be the cause. TEPCO says the condition may accelerate corrosion of aluminum racks holding spent fuel rods and may cause the rods to topple in the worst case, which could lead to re-criticality.

At the same time, TEPCO is preparing to install a circulatory cooling system at the fuel pool that will go into operation in early July.

Sunday, June 26, 2011 13:01 +0900 (JST)

Injection d'acide borique dans la piscine du réacteur 3

TEPCO a commencé dimanche matin à injecter de l'acide borique dans la piscine de stockage des barres de combustible usagé du réacteur 3 de la centrale de Fukushima.

L'opération a pour but d'éviter que les étagères soutenant les barres ne soient corrodées par l'eau alcaline. D'ici lundi, la compagnie d'électricité injectera 90 tonnes d'eau enrichie d'acide borique.

Le mois dernier, l'entreprise a découvert que l'eau de la piscine était devenue extrêmement alcaline, avec un pH de 11,2. A l'origine de ce problème, il y aurait un dégagement d'hydrate de calcium émis par les morceaux de béton tombés dans la piscine au moment de l'explosion d'hydrogène survenue dans le bâtiment du réacteur au mois de mars.

TEPCO ready to inject nitrogen into No.2 reactor

Tokyo Electric Power Company is ready to inject nitrogen into the containment vessel of the Number 2 reactor at its Fukushima Daiichi nuclear plant to prevent hydrogen blasts.

The company says it will monitor radiation levels around the compound more closely as the nitrogen may force out tiny amounts of gas containing radioactive substances.

Work is underway at the damaged nuclear plant to decontaminate water and inject it back into the reactor for cooling.

But if the reactors are cooled to a stable level, less moisture will be produced, raising the ratio of hydrogen in the air.

Hydrogen can cause an explosion when it reacts with oxygen.

TEPCO has been pumping nitrogen into the No.1 reactor since April and has completed preparations to do the same at the No. 2 reactor.

The utility assessed the possible effects of nitrogen injection into the No.2 reactor, and submitted its report to the government's Nuclear and Industrial Safety Agency on Friday.

It plans to start the injection as soon as it obtains the consent of the agency.

WWII uranium miner questions peaceful use of nuclear power

Kiwamu Ariga, who was mobilized for uranium mining toward the end of World War II, is pictured in Ishikawa, Fukushima Prefecture. (Mainichi)

ISHIKAWA, Fukushima -- A former elementary school principal who was once mobilized for uranium mining during World War II for Japan's development of nuclear weapons questions the peaceful use of nuclear power amid the ongoing nuclear crisis.

Kiwamu Ariga, 80, a former elementary school principal in Ishikawa, Fukushima Prefecture, has gathered testimonies by those who were engaged in uranium ore mining in the town as mobilized students toward the end of the war.

Last year, Ariga formed a citizens' group to pass on the stories of the war to future generations. Though he had believed the peaceful use of nuclear energy was inevitable, he changed his mind following the accident at the Fukushima nuclear plant. "I believe we have come to a point where we should review the peaceful use of atomic power from scratch," Ariga said.

The town of Ishikawa -- located about 60 kilometers southwest of the disaster-crippled Fukushima No. 1 Nuclear Power Plant -- has been home to rare element minerals since before the war. The then Imperial Japanese Army, which was developing atomic weapons toward the end of the war, mobilized some 120 third-year students at a private middle school in Ishikawa for uranium mining, including 14-year-old Ariga, in April 1945.

"All we did was to enter the mountain, dig minerals and carried them in baskets," recalls Eiji Fujisawa, 80, Ariga's classmate who also lives in Ishikawa.

In May of 1945, several engineer officers visited the mine and told the students, "If we make a bomb using the rocks you are mining, we could instantly wipe out New York," according to Ariga.

The amount of uranium mined in the town is said to have been too small to extract the necessary quantity for producing an atomic bomb. The Army's technical research institute, which had commissioned the development of atomic weapons to what is now Riken in Tokyo, concluded in June 1945 that even the United States would not be able to develop nuclear weapons and abandoned the idea of producing atomic bombs.

The United States, however, dropped atomic bombs on Hiroshima on Aug. 6 and Nagasaki on Aug. 9 that year, causing enormous devastation to the two cities. Ariga eventually became a teacher and started passing down his wartime experiences of mining uranium to younger generations in the hope that the tragedy of war will never be repeated.

In 1971 and 1982, the Fukushima No. 1 and No. 2 nuclear power plants started operations, respectively. Ariga had long thought the use of nuclear energy for power generation and in the medical sector was unavoidable, but the accident at the No. 1 plant in March this year prompted him to change his mind.

"Despite the fact that Japan suffered the tragedies of Hiroshima and Nagasaki, we have allowed the use of nuclear power on the grounds that it is for peaceful purposes. I think the nuclear accident occurred because we underestimated (the danger of) nuclear power," said Ariga.

For Ariga, the memory of the wartime period when people were told Japan would absolutely win the war, which proved contrary, and the postwar myth that nuclear power plants are absolutely safe, which was overturned by the Fukushima accident, overlap each other. He is planning to hold a meeting of his story-telling group this summer, hoping that he could convey the horror of atomic bombs and discuss nuclear power generation with participants.

Decontamination system to fully operate on Monday

The operator of the Fukushima Daiichi nuclear power plant says it hopes to begin full-scale operation on Monday of a system to decontaminate highly radioactive water.

Contaminated water is still accumulating in the plant, as water is being injected to cool the reactors.

Tokyo Electric Power Company was forced to suspend the test run of the system a number of times due to problems with a device that removes radioactive substances.

The utility says it managed to resolve the problem by using a different absorbent material for the devices, and the equipment that removes salt is working normally.

The company says it will review its procedures, and will consider replacing the absorption devices more frequently than once a month.

The storage facilities for contaminated water will not fill up until July 5th, as 5,400 tons was cleaned during the test runs and the contaminated water that was about to fill the reactor buildings can now be transferred.

However, it remains to be seen if the system can operate stably, as the pump of the salt-removal device failed on Saturday.

It is also feared that heavy rain during the rainy season or a typhoon may quickly fill up the storage facilities.

Sunday, June 26, 2011 23:31 +0900 (JST)

Le démarrage du système de décontamination de l'eau radioactive est prévu pour lundi

La Compagnie d'électricité de Tokyo, Tepco, prévoit de faire tourner à plein régime lundi le système de décontamination de l'eau hautement radioactive.

Cette eau continue de s'accumuler dans la centrale de Fukushima à mesure que les aspersions d'eau se poursuivent pour refroidir les réacteurs.

Tepco a été contrainte de suspendre les essais du système à plusieurs reprises en raison de difficultés avec un appareil d'absorption de substances radioactives. La compagnie s'efforce de résoudre le problème **en utilisant un absorbant différent**. Elle va également revoir ses procédures et **envisager de remplacer l'élément absorbant plus d'une fois par mois**.

Par ailleurs, l'appareil qui retire le sel fonctionne normalement.

Internal radiation exposure found in all 15 people surveyed in Fukushima

HIROSHIMA (Kyodo) -- Radiation experts said Sunday **they had found internal radiation exposure in all of the 15 people they surveyed in May in areas 30-40 kilometers from the crippled Fukushima Daiichi nuclear power plant**.

The experts surveyed 15 people aged between 4 and 77 in Iitate and Kawamata in early and late May, and found radioactive cesium in both batches of their urine samples.

Nanao Kamada, a radiation biologist who led the survey, said, "**There is no cause for concern unless the residents continue eating contaminated food such as vegetables, but it may be hard to continue living in the areas.**"

The survey also showed that radioactive iodine was detected in the first batch of urine samples from six of the 15 people but was not found in the second batch, they said.

(Mainichi Japan) June 27, 2011

LDP's Fukushima chapter adopts 'no nuclear plant' policy

FUKUSHIMA (Kyodo) -- The Fukushima prefectural chapter of the main opposition Liberal Democratic Party declared Sunday that it will no longer promote nuclear power generation.

The LDP, which held power for most of the postwar period until it was defeated by the Democratic Party of Japan in the August 2009 general election, has long promoted nuclear power.

"We will definitely not promote nuclear power generation in the future," said the chapter's policy platform for fiscal 2011 adopted during its regular convention in the wake of the crisis at the crippled Fukushima Daiichi nuclear plant.

(Mainichi Japan) June 27, 2011

Gov't airs program pushing for resumption of Genkai reactors

SAGA (Kyodo) -- The government sought local consent Sunday for the resumption of operations of reactors at the Genkai nuclear power plant of Kyushu Electric Power Co. in Saga Prefecture.

In a broadcast aired on the Internet, an official at the Economy, Trade and Industry Ministry said the authorities have taken sufficient measures to secure the safety of the Genkai plant following the nuclear emergency at the Fukushima Daiichi power plant.

It was the **first attempt by the central government to brief residents of municipalities that host nuclear power plants on nuclear safety measures.** The program was shot and aired at a cable TV studio in the city of Saga, and featured government officials and local residents.

Operation of the Genkai plant's Nos. 2 and 3 reactors have been suspended for regular checkups.

Despite the government's safety assurances, the local residents voiced concerns in the program as to why the state has requested only Hamaoka nuclear power plant in Shizuoka Prefecture to suspend operations.

The Hamaoka plant, which is located in a major active fault zone, was shut down in May following a government request.

In front of the cable TV station, some 150 members of an antinuclear group lodged a protest. They were led by Hatsumi Ishimaru, 59, who said, "This is a program designed to lead to approval for the resumption of operations of the Genkai reactors. We cannot accept that."

(Mainichi Japan) June 26, 2011

Cooling of reactors with recycled water to begin

Tokyo Electric Power Company says it will begin using decontaminated water as a coolant at the Fukushima Daiichi nuclear plant on **Monday afternoon.**

Highly radioactive water is still accumulating at the power plant from the constant stream being injected into the reactors to cool them down.

The utility says it has about 1,850 tons of decontaminated water that was processed in test runs of a water treatment system. It plans to circulate the water around the reactors on Monday afternoon at the earliest.

TEPCO says it hopes to start full-scale water decontamination **as soon as it determines the system's optimum operating conditions.**

The system became operational a week ago but had to be suspended after one of the US-made radiation-absorbing cartridges reached its limit sooner than expected.

If successful, the process will bring the plant one step closer to TEPCO's goal of stabilization by mid-July without additional new water injections.

Monday, June 27, 2011 12:48 +0900 (JST)

La décontamination de l'eau radioactive va reprendre

La Compagnie d'électricité de Tokyo, Tepco, envisage de redémarrer dès ce lundi un système de décontamination de l'eau hautement radioactive dans la centrale nucléaire Fukushima Dai-ichi.

L'eau contaminée continue à s'accumuler, les techniciens injectant de l'eau continuellement pour refroidir les réacteurs.

Tepco a dû suspendre les essais du système à plusieurs reprises, étant confronté à des problèmes liés au fonctionnement d'un dispositif d'élimination des substances radioactives.

Mais la compagnie annonce avoir réussi à résoudre le problème en utilisant un matériau absorbant différent pour le dispositif.

Tepco précise que 1850 tonnes d'eau contaminée ont été traitées au cours des essais et que l'eau recyclée sera utilisée pour refroidir les réacteurs dès ce lundi après-midi.

Radiation checkups start in Fukushima

Health checkups have started for people likely to have been exposed to relatively high levels of radioactive contamination from the Fukushima Daiichi nuclear plant.

Ten people were given checkups on Monday at a specialist facility near Tokyo. The authorities plan to test more than 2 million residents of Fukushima Prefecture.

The initial checkups will focus on about 28,000 residents of 3 municipalities near the plant -- Iitate Village, and the towns of Kawamata and Namie. Relatively high levels of radioactive contamination have been measured in these areas.

They will be asked to give details of their daily lives since the March 11th accident at the nuclear plant to estimate their external exposure.

More than 2,900 people will also be examined with a whole body counter to measure their internal exposure to radioactive contamination from the nuclear plant.

Full-scale health-checkups for all the residents of the prefecture will start in August.

Monday, June 27, 2011

Début des contrôles d'exposition aux radiations des habitants de la préfecture de Fukushima

Des contrôles de santé pour plus de deux millions d'habitants de la préfecture de Fukushima ont commencé ce lundi.

Les autorités préfectorales vont donner la priorité aux quelque 28 mille habitants des trois communautés proches de la centrale nucléaire Fukushima Dai-ichi, à savoir le village d'Iitate et les villes de Kawamata et Namie.

Une enquête portera sur le mode de vie de ces personnes après la double catastrophe du 11 mars qui a endommagé la centrale. Les niveaux d'exposition externes seront estimés en comparant le comportement des personnes interrogées aux données de radiation recueillies dans l'atmosphère et au sol.

Un appareil médical spécial sera utilisé pour vérifier les niveaux de radiation internes de plus de 2900 personnes.

Dilution of radioactive materials at sea is no solution to nuke-plant crisis

Whispers have emerged that Prime Minister Naoto Kan is prepared to dissolve the House of Representatives and face a general election over the issue of whether Japan should abolish nuclear power. To me, mere talk of such an issue is the ultimate example of the blurred vision at Japan's political center.

There is nothing wrong with asking the public whether nuclear power is right or not, but now is a time of national emergency -- a time when officials should be putting full effort into bringing the nuclear crisis in Fukushima under control and preventing environmental contamination. **There isn't time now to leisurely debate mid- and long-term government policies, haggle over the dissolution of the chamber and become engrossed in election campaign strategies.**

The reason for the situation comes from **politicians' delusion, grounded in their idea that the nuclear crisis is somehow being brought under control, and that the effects from radioactive material are minimal. But the fact is, the situation at the Fukushima No. 1 Nuclear Power Plant isn't returning to normal. And we still don't know just how much damage environmental pollution from the**

crisis will inflict on people and their DNA. There is no proof anywhere that this pollution will be harmless.

Some of the reactors at the nuclear power plant have melted down, and the melted nuclear fuel is sinking toward water under the ground. **An underground barrier is needed to stop water that becomes contaminated from flowing into the sea.** Experts have pointed out the urgency of the situation and the government supports the idea, but Tokyo Electric Power Co. (TEPCO), the operator of the crisis-hit nuclear plant, is saying "wait."

I wrote about this problem in a column on June 20, and a question on the issue arose at a regular news conference scheduled by the Nuclear and Industrial Safety Agency. Hidehiko Nishiyama, a spokesman for the agency, responded by saying, "We are implementing fundamental measures, **but we don't believe there is a need to rush.**"

The response lay within the scope of a set of answers that TEPCO had prepared as it braces itself for a general shareholders' meeting. But why such a reaction? Because the line of responsibility between TEPCO and the government is a fine one.

There is a feeling in the government that it is shoving the handling of the unprecedented nuclear crisis into the hands of TEPCO, a private company. The government therefore has a weak spot that forces it to listen when TEPCO comes crying about measures to prop up its share prices.

Why can the two sides only form a response marked by indecisiveness and reliance on each other as Japan faces this unprecedented crisis? I think it is because the problem is too big, and they can't grasp how far it is spreading and how serious it is.

In April, TEPCO announced that 520 tons of water that contains substances emitting 4,700 terabecquerels of radiation had leaked into the sea through cracks in nuclear plant facilities over a six-day period. This is close to the amount that was leaked into the sea over the course of a year at the Sellafield nuclear processing site in Britain in the 1970s in the worst case of maritime radiation contamination to date.

And the leaks that have surfaced are just the tip of the iceberg. Water that was used to cool the cores of the damaged reactors at the Fukushima plant has overflowed and contaminated underground water is moving toward the sea. An unprecedented case of maritime pollution is about to unfold.

All things considered, one could say this is only natural. Fukushima's nuclear power plants were the heart of Japan as an economic power. **The total output of the reactors that have been crippled by the disaster was close to 3 million kilowatts,** three times the output at Chernobyl.

Chernobyl was hit by a nuclear explosion while nuclear fission was taking place, and many people died from acute radiation disease. There was a tendency in Japan to look lightly on the Chernobyl disaster as occurring against a background of a decline at the end of the Soviet era. But the potential amount of the harmful "poison" that gradually eats away human life is greater in Fukushima.

It is common for people to simply think that if this poison were washed into the sea, it would become diluted. If that was all there was to the situation, the crisis could be easily solved. But now, experts are

pointing to the possibility of this unprecedented pollution developing into a major disaster that would last several decades, just like the Minamata and asbestos catastrophes in Japan.

In this March 11, 2011 file photo released by Tokyo Electric Power Co., waves of tsunami gush into a complex near the Unit 4 reactor at the Fukushima Dai-ichi nuclear complex in Okuma, Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

Delaying the construction of an underground barrier is not just an event occurring during a break in the season for general shareholders' meetings. It is a major issue that calls the essence of TEPCO's assertion of its "social responsibility as a company" into question. The prime minister needs to show leadership in initiating construction of an underground barrier. (By Takao Yamada, Expert Senior Writer)

(Mainichi Japan) June 27, 2011

TEPCO starts circulating cleaned water into crippled reactors

In this photo taken on June 22, 2011 and released on Thursday, June 23, 2011 by Tokyo Electric Power Co. (TEPCO), workers in protective suits set up temporary pressure gauges in the Unit 2 reactor building at the tsunami-damaged Fukushima No. 1 nuclear plant in Okuma, Fukushima prefecture. (AP Photo/Tokyo Electric Power Co.)

TOKYO (Kyodo) -- Tokyo Electric Power Co. said Monday it has started cooling the crippled nuclear reactors at the Fukushima Daiichi power complex by **using decontaminated water produced from a newly installed water treatment system.**

The start of "circulating injection cooling" is seen as a key step to achieve both the stable cooling of the Nos. 1 to 3 reactors and the reduction of highly radioactive water that is accumulating inside the plant's premises as a result of an emergency measure to keep injecting water into the reactors from outside.

"We've taken a large step" in efforts to restore the crisis-hit plant, Goshi Hosono, a special adviser to Prime Minister Naoto Kan on handling the nuclear disaster, said at a press conference announcing the start of the water circulation in the afternoon.

The plant operator known as TEPCO has recently set up a water treatment system designed to remove radioactive substances from the highly contaminated water, although it has been plagued by water leakage and other trouble with the system.

Still, **about 1,850 tons of clean water has been produced in trial runs of the system.**

Some **110,000 tons of highly contaminated water**, including coolant liquid leaking from damaged reactors, is estimated to have accumulated inside the plant's reactor turbine buildings and nearby areas, and there are fears the water may overflow into the Pacific Ocean.

Hidehiko Nishiyama, a spokesman for the government's Nuclear and Industrial Safety Agency, said at a press conference earlier Monday the main focus of the circulating injection cooling at the beginning would be on reducing the amount of polluted water to lessen the risks of overflowing.

Hit by the magnitude 9.0 earthquake and tsunami waves on March 11, the six-reactor nuclear complex lost nearly all its power sources, causing the cooling functions of the reactors and spent nuclear fuel pools at the Nos. 1 to 4 units to fail.

The Nos. 1 to 3 reactors' cores are assumed to have suffered meltdowns, although the melted fuel is now believed to be kept cool at the bottom of each reactor pressure vessel because of the emergency water injection measure.

(Mainichi Japan) June 27, 2011

Yamaguchi governor bans construction of nuclear power plant

YAMAGUCHI -- The governor has refused to extend permission for the construction of a nuclear power plant in the prefecture, citing the central government's failure to clarify its energy policy and to reveal strengthened safety measures at nuclear power stations.

"So far, the national government has failed to clearly show its nuclear energy policy and improved safety measures at nuclear power plants. Amid such uncertainty, we can't initiate the construction of any such plant," Yamaguchi Gov. Sekinari Nii told a regular session of the prefectural assembly on June 27.

During the session, Nii strongly urged the national government to clarify its energy policy following the crisis at the tsunami-hit Fukushima No. 1 Nuclear Power Plant.

"First of all, the central government should clarify how it characterizes nuclear power generation in its new overall energy policy and how it will plan the construction of new nuclear power plants, including Kaminoseki plant," he told the assembly session.

He made the remarks in reference to an application Chugoku Electric Power Co. is expected to file for an extension of the prefectural government's permission to reclaim sea areas off the prefecture town of Kaminoseki where the Hiroshima-based power supplier is planning to build a nuclear power plant.

In a meeting with reporters following the session, Nii reiterated that the prefectural government will not extend permission under the current circumstances. "Chugoku Electric should continue its suspension of the reclamation work. As long as the current situation continues, we can't approve the extension even if we receive an application from the utility."

The governor's stance is expected to cause a considerable delay in the construction of the Kaminoseki Nuclear Power Plant.

Under the plan, Chugoku Electric Power will reclaim a 14-hectare area of the sea to develop a 33-hectare area, where it will build two nuclear reactors. Chugoku Electric Power had planned to begin construction of the No. 1 reactor of Kaminoseki Nuclear Power Plant in June 2012 and start operating it in March 2018.

However, its reclamation of the sea has been stalled as local residents opposing the construction staged an anti-nuclear power campaign. Moreover, the national government's screening of applications for permission to build nuclear reactors has been suspended since the Fukushima nuclear crisis. The permission that the power supplier has obtained is set to expire in October next year.

Furthermore, assemblies in municipalities around the area have adopted various resolutions urging that the construction of the Kaminoseki power station be either suspended or cancelled.

Chugoku Electric Power has declined to comment on the governor's comments. "Since we're trying to confirm what the governor meant, we can't comment on his remarks."

Kaminoseki Mayor Shigemi Kashiwabara, who is supporting the construction of the nuclear power station, also said, "Since I don't understand what the governor meant, I'd like to refrain from commenting on his statements."

(Mainichi Japan) June 27, 2011

News Navigator: How are nuclear reactors decommissioned?

The Mainichi answers common questions readers may have about the decommissioning of nuclear reactors in the wake of the crisis at the Fukushima No. 1 Nuclear Power Plant.

Question: Calls have arisen across Japan for the decommissioning of nuclear reactors following the nuclear crisis in Fukushima. How are reactors decommissioned?

Answer: Decommissioning involves safely dismantling a reactor and removing all facilities on the site. After commercial operation of the reactor is halted, work begins to remove spent nuclear fuel from the reactor building using cranes. Up until now, the fuel has been shipped to a reprocessing facility such as the one in Rokkasho, Aomori Prefecture. Chemicals are used to remove radioactive materials in pipes and containers in the emptied nuclear reactor building, and the facility is left standing for about 10 years to allow any remaining radiation inside to decrease. The Japan Atomic Power Co.'s **Tokai** nuclear power plant, whose decommissioning began in 2001, is now at this stage. When the radiation levels have decreased sufficiently, dismantling work can finally begin. **The time needed to complete the work depends on the size and type of reactor, but usually the total process takes over 20 years.**

Q: That's quite a long time. How long will the decommissioning of the reactors at the Fukushima No. 1 Nuclear Power Plant take?

A: Unfortunately that remains unclear. Fuel in reactors is believed to have melted and to be lying at the bottom of the reactor pressure vessels, meaning that **the regular method of removing the fuel in its original form is not an option.** Toshiba Corp., which undertook construction of the power plant, has presented plans to Tokyo Electric Power Co. and the Ministry of Economy, Trade and Industry to complete the decommissioning of the reactors in 10 years at the earliest. It says this is possible thanks to industry know-how on the retrieval of melted fuel obtained during the cleanup of the Three Mile Island nuclear accident in the U.S.

Q: Can we expect these plans to be successful?

A: Some people are doubtful. The British journal Nature carried a paper suggesting that decommissioning would take anywhere from several decades to 100 years. Going by the testimonies of a former worker involved in the Three Mile Island cleanup and other factors, it is predicted that decommissioning of reactors in Fukushima -- where hydrogen explosions scattered radioactive material -- **will be technically difficult. Moreover, the more time that it takes, the bigger the cost will be.** It is expected to cost 37.9 billion yen to decommission the No. 1 reactor at the Hamaoka Nuclear Power Plant operated by Chubu Electric Power Co., which is the same kind as the reactors at the Fukushima plant, but at least one think-tank estimates that **the cost of decommissioning work at Fukushima could reach 15 trillion yen.**

Q: Why will it cost so much?

Because **it's necessary to build lots of new equipment designed especially to handle the accident**, such as a purification system to remove radioactive materials from contaminated water that has built up on the grounds of the power plant. **New legislation may also be needed**, as the current Act on the Regulation of Nuclear Source Material, Nuclear Fuel Material and Reactors does not provide for the high concentrations of radioactive material that some fear could leak from the plant. (Answers by Hiroshi Higa, Science and Environment Writer)

(Mainichi Japan) June 27, 2011

EPR de Flamanville : Bouygues rompt un contrat avec un sous-traitant

LEMONDE.FR avec AFP | 27.06.11 | 13h30

AFP/JEAN-PAUL BARBIER

Bouygues a rompu son contrat avec Atlanco, un de ses sous-traitants sur le chantier de l'EPR à Flamanville, indique, lundi 27 juin, le géant du BTP, au centre d'une affaire d'accidents du travail non déclarés relevés par l'Autorité de sûreté nucléaire (ASN).

Le contrat rompu, les soixante-dix à quatre-vingts employés polonais du sous-traitant ont été renvoyés ce week-end, selon la CGT. Bouygues, qui pilote le génie civil sur le chantier, justifie cette rupture par *"des questions de réglementations extrêmement compliquées à régler au niveau européen"*.

La semaine dernière, l'ASN, l'organe de contrôle du nucléaire français, a transmis à la justice un procès verbal recensant cent douze accidents du travail survenus en 2010 sur le chantier, dont trente-huit accidents *"à déclarer n'ayant pas fait l'objet d'une déclaration"*, selon une copie obtenue par l'AFP. D'après le procès-verbal adressé au procureur de Cherbourg, Atlanco, société de travail temporaire basée à Chypre, a omis de déclarer six accidents du travail. L'ASN déplore par ailleurs des irrégularités dans ses déclarations de cotisations sociales, selon des sources concordantes.

"ON LES VIRE COMME DES MALPROPRES"

En outre, *"Atlanco s'est dépêché d'organiser en plein week-end le départ de la région de tous ses salariés dans des conditions complètement illégales"*, selon un délégué syndical CGT, [Jacques Tord](#), salarié chez EDF. *"C'est la double peine. Non seulement on les exploite, mais en plus on les vire comme des malpropres"*, a-t-il dit à l'AFP. En mai, certains salariés polonais s'étaient mis en grève : *"sur 2 000 euros bruts de salarié, on leur retirait 600 à 700 euros par mois, soi-disant de cotisations fiscales et sociales, alors qu'ils n'étaient pas assurés et payent des impôts en Pologne"*, raconte M. Tord.

Le chantier de l'EPR a déploré ces derniers mois trois accidents du travail mortels. Le 11 juin un salarié de 32 ans de la société Endel est mort après une chute de 10 mètres. Le 24 janvier, un intérimaire de 37 ans employé par la société Normetal avait fait une chute mortelle qui a entraîné l'ouverture à Cherbourg d'une enquête en flagrance pour *"homicide involontaire"*. La semaine dernière, un ouvrier qualifié d'Areva, est mort dans un accident de la route en quittant le chantier, selon EDF et les gendarmes.

Le chantier accuse un retard d'au moins deux ans alors que le réacteur nucléaire de troisième génération – EPR – de Flamanville, un des tout premiers en construction dans le monde, fait figure de vitrine.

tu te rappelles ? le coup des 4 km de tuyaux ?

TEPCO halts water circulation due to leaks

The operator of the Fukushima Daiichi nuclear power plant has suspended using decontaminated water as a coolant because of leaky pipes.

Tokyo Electric Power Company began circulating recycled water through the No.1, 2 and 3 reactors at 4:20 PM on Monday.

But it halted the operation one and a half hours later after discovering water leaking from the pipes.

TEPCO has been attempting to run the decontamination system since June 14th. It has so far treated about 1,850 tons of the water.

The operator hopes to reduce the levels of radioactive wastewater accumulated at the plant as a result of injecting fresh water into the damaged reactors.

Circulating the decontaminated water around the reactors is considered an important step to stabilize them by mid-July as planned. It will also help prevent the volume of wastewater from increasing.

TEPCO says it will repair the leaks and hopes to resume water circulation soon.

Monday, June 27, 2011 20:40 +0900 (JST)

Radioactive ash found in waste incineration plant

An operator of waste incineration plants in Tokyo says it has found a high density of radioactive materials in ash at one of its plants.

An Edogawa ward plant, which handles general household garbage, detected **9,740 becquerels of radioactive materials per kilogram of ash.**

The ash was collected from a device to filter exhaust fumes.

The plant's operator, an organization jointly set up by Tokyo's 23 wards, believes that radioactive cesium built up through the incinerating process.

But it says there is no danger of the toxic substances escaping into the environment as they were trapped by the filter.

Legally, the plant can only bury ash registering 8,000 becquerels or less per kilogram.

But ash contaminated with more than 8,000 becquerels must be stored until the government determines a safe disposal method.

Following the latest findings, Tokyo consulted the central government and decided to temporarily store the contaminated ash inside the plant.

Tokyo on Monday asked the government to come up with guidelines for the ash's disposal.

Tuesday, June 28, 2011

Water recycling at Japan nuclear plant stops again

TOKYO (AP) -- A water recycling system at Japan's damaged nuclear power plant was halted for repairs Monday after a brief run that had been hailed as major progress in restoring control and improving conditions at the crippled plant.

Tons of fresh water has been pumped to the plant to cool its reactors, a process that taints the water with radiation. About 110,000 tons of tainted water has accumulated and could overflow by early July if the recycling system fails or other storage options are not enough.

Workers have struggled for weeks to use a new system to clean the tainted water and reuse it in the cooling process. The water treatment components fully operated for five hours earlier this month, and test-runs were conducted before it went fully operational Monday. It also pumped treated water into the reactors -- a long-awaited new phase that lasted only briefly.

Plant operator Tokyo Electric Power Co. said the recycling system was halted about an hour and a half after it began operating. Workers spotted water leaking from a hose that was sending the processed water into the reactors, TEPCO spokesman Junichi Matsumoto said.

The leak shut down the recycling segment of the system, while the cleaning segment is continuing to operate. **Workers switched back to fresh water injection into the reactors**, Matsumoto said.

No new leakage outside the plant has been reported. TEPCO plans to start repair work early Tuesday to restore the recycling segment as soon as possible, hopefully by the end of the day.

The multinational system has reprocessed 1,850 tons of contaminated water as coolant to be pumped back into the reactors. In full capacity, the system can treat up to 1,200 tons of contaminated water per day, more than twice as much as needed to cool the three reactors.

The March earthquake and tsunami destroyed power and cooling systems at the Fukushima Dai-ichi plant, melting reactor cores and leaking massive amount of radiation. Some contaminated water seeped into the ocean in April and May, causing criticism and concerns in and outside of Japan.

Some of the tainted water is stored in temporary tanks, but the rest has still pooled inside reactor and turbine basements and utility pits, hampering workers and risking radiation exposure.

TEPCO has sealed cracks, set up oil fences around the coastal plant, and acquired more storage tanks in case of emergency. **But as long as the cleaning segment of the recycling system is functioning, the volume of tainted water will not grow.** [not necessarily true : it depends how much water TEPCO can process at what speed]

Announcing the launch of the recycling system earlier Monday, Goshi Hosono, newly appointed nuclear crisis minister, called the system "a major step forward" toward stable cooling of the reactors. But he said he was not fully confident about the system.

"It's a problem if the system continues to be unreliable," he said. "We must turn it into something that can feed water stably."

TEPCO and the government have said they hope to achieve a cold shutdown of the reactors by January by bringing the core temperatures to below 100 Celsius (212 Fahrenheit).

(Mainichi Japan) June 28, 2011

TEPCO checking water circulation system

The operator of the Fukushima Daiichi nuclear plant is checking its trouble-hit water-recycling system to try and get it running again as soon as possible.

Tokyo Electric Power Company was forced to halt the new system on Monday after only about an hour and a half of operation due to water leakage.

TEPCO said on Tuesday that water burst from a weak connection that wasn't checked in advance.

It said the leak lasted for 2 minutes at most, and that about a single ton of water seeped out.

Under the recycling system, highly radioactive water is pumped out of reactors, decontaminated and then circulated back inside the reactors as coolant.

TEPCO believes the system holds the key to cooling down the reactors, while decreasing the amount of contaminated water that is threatening to overflow.

Tuesday, June 28, 2011

Nuclear plant operator skipped pipe check

The operator of the Fukushima Daiichi nuclear plant says it skipped a scheduled test of the plant's water pipes on Monday, shortly before it was forced to suspend a water recycling operation due to leaks.

The utility ran the filtering system, designed to recycle contaminated water for use in cooling the reactors, for just 90 minutes on Monday before treated water was found leaking from unfastened pipes.

The operator says it failed to check the 4 kilometers of piping as it had found no problem during an inspection more than 2 weeks ago.

The company says it will review that decision.

The utility is under pressure to commence the recycling system as the contaminated water may start overflowing around July 5th.

Tuesday, June 28, 2011

Gov't urges 3 more prefectures to examine radiation levels in food

TOKYO (Kyodo) -- A government task force on the nuclear emergency said Monday it has decided to call on three more prefectures to examine radioactive materials in food, while adding tea, wheat and fishery products as individual items to be monitored.

A rule on radiation in food the panel set in early April has so far targeted four prefectures including Fukushima, where the government has banned shipments of farm products after the accident at the Fukushima Daiichi nuclear power plant, and the surrounding seven prefectures.

In addition to the prefectures, the revised rule will urge Kanagawa, Yamanashi and Shizuoka prefectures to check radiation levels in food as the crisis at the power station crippled by the devastating March 11 earthquake and ensuing tsunami is prolonged, the panel said.

The Nuclear Safety Commission of Japan has advised the panel to establish a new rule to ensure food safety against radioactive contamination instead of interim limits set under the food sanitation law as soon as possible, it said.

(Mainichi Japan) June 28, 2011

Radioactive strontium detected in seabed

Radioactive strontium has been detected for the first time on the seabed near the crippled Fukushima Daiichi nuclear power plant.

Tokyo Electric Power Company says it found strontium-89 and -90 in the seabed soil. The company conducted a survey on June 2nd about 3 kilometers off the coast at 2 locations, some 20 kilometers north and south of the nuclear complex.

The substances pose a serious health risk because they can accumulate in the bones if inhaled, which could cause cancer.

Up to 44 becquerels per kilogram of strontium-90 were detected, which has a half-life of 29 years.

The substances had been detected before in soil on land and in seawater following the nuclear accident in March.

A member of the government's Nuclear Safety Commission, Shigeharu Kato, says more examination should be carried out to find out if or how the substances can accumulate in marine life.

The fishery ministry conducted separate surveys. It did not find radioactive strontium in fish and seafood samples taken off the coast of Ibaraki and Chiba prefectures. Both are located south of the Fukushima plant.

et bien voilà, on sait la somme maintenant :

France nuclear power funding gets 1bn euro boost

France will invest 1bn euros (£0.8bn) in nuclear power despite warnings after the Fukushima disaster in Japan, President Nicolas Sarkozy says.

The new investment will **include a boost for research into nuclear safety.**

The French nuclear giant Areva is developing the fourth generation of reactors. France gets 80% of its electricity from nuclear power.

Earlier this year neighbouring Germany, Switzerland and Italy voted against nuclear power, following Fukushima.

The BBC's Christian Fraser in Paris says that as president of the G8 and G20 industrial groups, Mr Sarkozy has been pushing for an international standard on nuclear safety.

"We are going to devote a billion euros to the nuclear programme of the future, **particularly fourth-generation technology,**" Mr Sarkozy told a news conference.

"We are also going to release substantial resources from the big loan to strengthen research in the sphere of nuclear safety."

He stressed his government was still investing "massively" in renewable energy. He announced 1.35bn euros of investment for that sector.[\[je demande à voir les comptes\]](#)

But our correspondent says it is obvious how important nuclear power is to the French economy and its energy security.

The Fukushima Dai-ichi nuclear plant's cooling systems were knocked out by the 11 March earthquake and tsunami in Japan. The disaster caused a meltdown at three of the reactors and the plant is still leaking radiation. Tuesday, June 28, 2011

Russia has 'no plans' to undergo EU nuclear stress tests: Rosatom

Brussels (Platts)--28Jun2011/609 am EDT/1009 GMT

<http://www.platts.com/RSSFeedDetailedNews/RSSFeed/ElectricPower/8049894>

Russia has no plans to submit its nuclear reactors directly to EU-style safety stress tests, Kirill Kormarov of Russian state energy corporation Rosatom told Platts in Brussels late Monday.

"We don't want to fulfill the EU stress tests--**we've done tests already**," Kormarov, who is deputy general director for global business development at Rosatom, said on the sidelines of an industry debate on the future of nuclear in central and eastern Europe.

The EU agreed common criteria in May for safety tests to be carried out on all 143 EU reactors starting June 1. The move came in response to Japan's nuclear crisis at Fukushima earlier this year, and **the EC has also pushed for the EU's neighbors to agree to a similar nuclear safety review.**

The EC's nuclear energy director Peter Faross said during the debate "that there is a will for Russia to use the EU system." But when faced with Kormarov's comments, Faross told Platts that although there were no obstacles to Russia participating in EU stress tests, currently there is only a "joint declaration to contribute to transparency and to participate in the peer review [a review of national safety reports at an EU level by the European nuclear regulators' group Ensreg]."

The declaration was signed on June 23 by the EC and Armenia, Belarus, Croatia, Russia, Switzerland, Turkey and Ukraine.

"First we'll have to see [Russia's] national report and there will be a meeting in July on this," Faross said.

Russia's state energy regulator completed its own tests on nuclear reactors in May and will be spending some \$200 million in additional safety measures this year, including additional pumps and generators for the plants, said Kormarov. Russia is ready to exchange the results of the two independent stress tests it has completed, he added.

Russian reactors have also undergone tests from **Wano**, the world association for nuclear energy operators, which includes technical expertise from French utility EDF, Kormarov said.

For its part, the EC has no estimates of how much the EU stress tests will cost.

"It is the first time that we [group together] countries and industry using stress tests," Faross said.

Necessary work outlined by national regulators would fall under national government budgets, but any work deemed necessary by the EU peer reviews, which would follow national analysis, would fall under the EU budget, he said.

The EC is to give a first progress report on the tests to EU leaders on December 9, and the full process is to be completed by mid-2012.

The EC's next step is to push for an international accord on set measures for nuclear safety in September, Faross said.

--Jane Morecroft, newsdesk@platts.com

EPCO restarts water-circulation cooling

The operator of the troubled Fukushima Daiichi nuclear power plant has restarted its new water-recycling cooling system after repairing leaky pipes.

The Tokyo Electric Power Company, or TEPCO, activated a pump for the water injection system on Tuesday afternoon, after checking pipe connections and taking measures to prevent a sharp rise in water pressure.

The Nuclear and Industrial Safety Agency says the system is working steadily.

TEPCO was forced to halt the system on Monday after only about 90 minutes of operation due to a water leak. The firm said the leak lasted for 2 minutes at most, and that about one ton of water seeped out.

TEPCO said water burst from a weak connection, and that the firm had not taken originally planned measures to prevent a sharp rise in water pressure.

The system is designed to pump highly radioactive water out of reactor buildings, decontaminate it and circulate it back into the reactors as coolant.

TEPCO says the system is the key to cooling the reactors while decreasing the amount of contaminated water threatening to overflow.

Tuesday, June 28, 2011

TEPCO starts covering No.1 reactor building

The operator of the Fukushima Daiichi nuclear plant has begun building a **giant polyester shield over the damaged Number 1 reactor building to contain the spread of radiation.**

One of the largest cranes in Japan has been brought to the site for the construction. It has a 140 meter-long arm that can lift up to 750 tons.

The crane will be used to install a fabric cover around the reactor building. Before that, it will be used to remove debris from the top of the building, which was shattered by a hydrogen explosion one day after the earthquake and tsunami on March 11th.

Tokyo Electric Power Company says that when the shield is installed, the entire structure will be about

54 meters high.

Meanwhile, offsite at Onahama Port about 50 kilometers from the nuclear plant, the utility is preassembling 62 steel components that will be joined to create a rigid frame. The frame will support one millimeter-thick polyester fiber panels.

The components will start arriving at the plant in July. Work to assemble them will be done by the crane. The utility says the process will minimize the number of workers who must spend time at the site and lessen their radioactive exposure. TEPCO hopes to complete the cover by late September.

Tuesday, June 28, 2011

U.S. defends plutonium tests in response to protests from Hiroshima

HIROSHIMA (Kyodo) -- U.S. officials have defended the recent experiments conducted by the United States to examine the effectiveness of nuclear weapons using minute amounts of plutonium in letters to local leaders in Hiroshima, the Hiroshima prefectural and city governments said Tuesday.

Replying to letters from the leaders protesting against the tests conducted in March and last November, the officials said the experiments "support" President Barack Obama's speech made in Prague in April 2009, in which he declared his intention to create a world free of nuclear weapons and said it is time for nuclear weapons testing to be banned.

The officials' letters noted that the experiments conducted using the Sandia National Laboratory's "Z Machine" in New Mexico in March "produce essential scientific data and technical information" as part of efforts to "maintain the safety, security and effectiveness of the U.S. nuclear stockpile without conducting underground nuclear tests."

One of the letters, signed by U.S. Ambassador to Japan John Roos, was addressed to Hiroshima Gov. Hidehiko Yuzaki, and the other was addressed to Hiroshima Mayor Kazumi Matsui and signed by Robert Luke, minister-counselor for political affairs at the U.S. Embassy in Tokyo.

Yuzaki and Matsui had separately sent letters of protest to Obama in May.

(Mainichi Japan) June 29, 2011

Evacuation areas from crippled nuclear plant may be reduced: Hosono

Japanese policemen gather as they prepare search for bodies in the area devastated by the March 11 earthquake and tsunami in Minamisoma, Fukushima Prefecture, northeastern Japan, Thursday, April 21, 2011. (AP Photo/Sergey Ponomarev)

TOKYO (Kyodo) -- Areas subject to evacuation near the crippled Fukushima Daiichi nuclear power plant could be narrowed down as early as the middle of next month, Goshi Hosono, newly appointed minister to deal with ongoing nuclear crisis, said Tuesday.

"We are making efforts to enable some people to return to their homes after Step 1 is completed (around July 17) and we are sure that no hydrogen explosion will take place," Hosono said in a speech.

According to the timetable revealed on April 17 by plant operator Tokyo Electric Power Co. to bring the plant under control, Step 1 refers to the first three months to achieve "steady reduction" in radiation.

Hosono said it is "unlikely now that the nuclear reactor will run out of control" but stressed the need for caution since some experts cannot rule out the risk of a hydrogen explosion.

Meanwhile, Chief Cabinet Secretary Yukio Edano struck a positive note in reviewing the current evacuation areas, telling a news conference that there are "more than a few areas in places subject to evacuation that have levels of radiation that do not pose health risks."

A bicycle is left near the station in the part of the town of Minamisoma, which is inside the 20-kilometer (12-mile) evacuation zone, in Fukushima Prefecture, Japan, Thursday, April 21, 2011. (AP Photo/Sergey Ponomarev)

After the devastating March 11 earthquake and tsunami triggered the nuclear emergency, the government ordered the evacuation of people living within a 20-kilometer radius of the plant and directed those in the 20- to 30-km ring to stay indoors or voluntarily leave the area.

The government later added some municipalities outside the designated list of areas for evacuation due to concerns over high cumulative levels of radiation exposure, and banned people from entering areas within the 20-km area.

TEPCO halts reactor cooling system again

The operator of the Fukushima Daiichi nuclear plant has had to halt its new reactor cooling operation once again after finding more leaks in the system.

Tokyo Electric Power Company says it suspended operations on Wednesday morning after workers detected water leaking from 2 small holes in the system's piping.

It plans to restart the system as soon as it has fixed the faulty sections and checked for more leaks.

On Monday, TEPCO was forced to halt the system after only 90 minutes of operation due to water leakage from a displaced joint that connects plastic hoses.

The system was restarted on Tuesday afternoon, but small water leaks from another joint were later found.

The cooling system is designed to decontaminate radioactive wastewater accumulating at the plant and reuse the treated water to cool the reactors.

TEPCO says the system holds the key to stabilizing the reactors and reducing the amount of contaminated water.

But achieving stable operation of a system with 4-kilometers worth of piping is proving to be a challenge.

Wednesday, June 29, 2011

TEPCO restarts new cooling system

The operator of the Fukushima Daiichi nuclear power plant restarted its new reactor cooling system on Wednesday after fixing faults in the hosing.

Tokyo Electric Power Company was forced to suspend the system's operation earlier in the day after plant workers detected water leaking from 2 holes in the hosing.

On Monday, TEPCO halted the system after 90 minutes of operation due to water leakage from a displaced joint connecting plastic hoses.

The system was restarted on Tuesday afternoon, but more leaks from another joint were found.

After the series of leaks, TEPCO says it will look at ways to strengthen the system's hosing.

Also on Wednesday, workers found water leaking from a storage tank for decontaminated water.

TEPCO says the leak stopped after about 2 hours. It is now investigating the cause.

The cooling system is designed to decontaminate radioactive wastewater accumulating at the plant and reuse the treated water to cool the reactors. The leaky tank is part of its devices to filter radioactive materials and salt.

TEPCO says the system holds the key to stabilizing the reactors and reducing the amount of contaminated water.

Wednesday, June 29, 2011

TEPCO repeatedly halts water treatment system due to alarm

TOKYO (Kyodo) -- Tokyo Electric Power Co. said Wednesday that it was repeatedly forced to suspend operation of a newly installed radioactive water treatment system at its crippled Fukushima Daiichi nuclear power plant after an alarm, warning of malfunction, sounded.

The utility company, known as TEPCO, resumed operation of the "circulating injection cooling" system late Wednesday night. It was halted twice earlier in the day -- once due to water leakage from holes in a hose connecting a storage tank and a pump that sends water to the reactors and again after an alarm went off, warning of troubles at water treatment devices.

While the system was down, TEPCO continued operations to cool the troubled nuclear reactors at the power plant using decontaminated water, company officials said.

Repeated problems with the water treatment system have prevented the utility from commencing stable cooling operations using recycled water.

Faced with the impending overflow of highly radioactive water accumulating in the complex into the sea and high radiation levels in reactor buildings, the system's continuous operation is vital for containing the crisis.

The first alarm went off around 2:50 p.m. as water leaked from a tank that temporarily stores water decontaminated by an installation developed by France's Areva SA, the company said, adding that water overflowed from the tank onto its pan after workers opened its lid.

The hose in which the holes were found is made of polyvinyl chloride, measuring 10 centimeters in diameter and 20 meters long, the utility said.

Regarding the water treatment devices, around 50 tons of water was also found to have leaked from a drainpipe under a tank of a component that removes salt from decontaminated water, but the leak stopped after workers closed off the pipe, TEPCO said.

The plant operator restarted the operation around 6:45 p.m., but again halted it when an alarm indicating an abnormality sounded.

TEPCO said that workers also entered the fifth floor of the building housing the No. 4 reactor Wednesday to check the working environment and equipment in preparation for the creation of a system to efficiently cool the spent nuclear fuel pool inside, which lost its cooling function after the devastating March 11 earthquake and tsunami.

The "circulating injection cooling" system has run into repeated problems. On Monday, TEPCO halted water injection shortly after it started sending cooling water into reactors because water leaked from a hose carrying cleaned water to reactors from a storage tank. The utility resumed operation Tuesday but problems continued, with water found trickling near a pump.

(Mainichi Japan) June 30, 2011

Improperly set valve halts water treatment system

Tokyo Electric Power Company, or TEPCO, says an improperly adjusted valve has led to a halt in the operation of a key water decontamination system at the Fukushima Daiichi nuclear power plant.

TEPCO has repeatedly suspended the water decontamination operation. The operation is vital to reducing the amount of highly radioactive water building up in the plant. The treated water is also circulated to cool down the reactors.

At around 7 PM on Wednesday, TEPCO had to shut down the system again after contaminated water was found overflowing in a French-made radiation removal unit. An investigation found that an incorrectly set valve is most likely to blame.

The decontamination operation resumed two hours later.

At the Number 6 reactor's turbine building, low-level contaminated water is increasing. TEPCO plans to start on Thursday afternoon transferring low-level radioactive water stored in make-shift tanks into a giant steel barge called "megafloat" attached to a quay on the plant's premises.

The tanks are nearing their full capacity of 12,000 tons. TEPCO aims to pump around 8,000 tons of contaminated water into the giant barge in three or four months.

L'AIEA plaide en faveur d'un renforcement de la sûreté nucléaire... sans en avoir les moyens

A l'issue de la conférence ministérielle post-Fukushima de l'Agence internationale de l'énergie atomique (AIEA), réunie à Vienne du 20 au 24 juin, les 151 pays membres ne se sont pas dotés de normes contraignantes en matière de sûreté nucléaire.

Tout a semblé joué d'avance à la conférence ministérielle extraordinaire de l'[AIEA](#) organisée à Vienne (Autriche), siège depuis 1957 de cette agence onusienne, trois mois après l'accident de la centrale de Fukushima. Dès le premier jour, la déclaration finale était diffusée, soulignant *"les bénéfices du renforcement d'une expertise internationale de haute qualité, en particulier dans le cadre de l'AIEA, à travers des évaluations périodiques des cadres réglementaires nationaux"*, résumant un compromis qui, cependant, ne prévoit pas l'élargissement du mandat de l'AIEA mais se bornera à conduire à l'adoption d'un plan d'action en septembre. A la tribune de la plénière, les discours des ministres se sont succédés, plaidant tous pour une [sûreté et une transparence renforcées](#), gage de reconquête d'une opinion publique inquiète.

Un des temps forts de la semaine aura été la présentation par M. Weightman, inspecteur nucléaire britannique, des [résultats de la mission internationale](#) qu'il a conduite à Fukushima pour l'AIEA du 24 mai au 2 juin. Tout en se gardant de critiquer directement la [gestion de l'accident par l'opérateur TEPCO](#) et par les autorités japonaises, la mission a présenté la liste des enseignements de l'accident. M. Weightman a enjoint les Etats à *"ne jamais être complaisants, toujours chercher à améliorer la sûreté, car ce sont toujours les plus aptes qui survivent"*, faisant allusion à la théorie de l'évolution de Darwin.

Proximité des parties prenantes

Le rapport d'évaluation présenté par M. Weightman a souligné l'importance *"essentielle"* d'améliorer l'indépendance des régulateurs chargés de contrôler la sûreté des centrales. Dans son discours prononcé lors de la plénière du 20 juin, Banri Kaieda, ministre japonais de l'économie, du commerce et de l'industrie, a annoncé, dans le même ordre d'idées, que l'agence japonaise chargée de la sûreté nucléaire ([NISA](#)) serait rendue indépendante du METI (ministère de l'industrie).

Mais l'intrication entre industrie nucléaire et élaboration des régimes de sûreté demeurera, comme l'a affirmé Daniel Poneman, vice-ministre américain de l'énergie, pour qui elle semble aller de soi : *"Les compagnies d'énergie nucléaire et l'industrie nucléaire internationale continueront à jouer un rôle central dans la prévention et le traitement des accidents"*. Cette proximité du régulateur et du régulé est une caractéristique assumée du secteur. L'association mondiale des opérateurs nucléaires (WANO), pilotée par le Français Laurent Stricker, et l'association mondiale du nucléaire (WNA), dirigée par l'Américain John B. Ritch, ont été les chevilles ouvrières du groupe de travail sur l'amélioration de la sûreté nucléaire réuni cette semaine à l'AIEA.

Lors d'une conférence de presse le 21 juin, Gregory Jaczko, directeur de la Nuclear Regulatory Commission (NRC), l'autorité de sûreté nucléaire des Etats-Unis, a annoncé que les audits en cours des 104 réacteurs américains n'avaient pas conclu à la nécessité de mettre à l'arrêt une centrale. La centrale californienne de Diablo Canyon, située sur une faille sismique majeure, ne présente pas de danger, selon M. Jaczko. Les systèmes de refroidissement des 27 réacteurs BWR américains - du type de ceux de Fukushima – sont opérationnels, selon M. Jaczko, qui a approuvé l'idée de renforcer les *peer reviews*, ces inspections internationales prônées par le Japonais Yukiya Amano, directeur général de l'AIEA. Mais le directeur de la NRC a souligné que l'AIEA n'aurait pas les moyens d'effectuer des

inspections dans chaque centrale américaine et souscrit à l'idée d'inspections effectuées au hasard. Au final, selon les [conclusions des groupes de travail](#) diffusées ce 24 juin, ce seront d'abord les installations les plus anciennes qui pourront être inspectées en priorité. Une décision laissée à la discrétion des Etats, dont l'AIEA dépend statutairement pour toute extension de ses futurs mandats en matière de nucléaire civil.

Trace amounts of radioactive materials found in Fukushima kids' urine

TOKYO (Kyodo) -- Trace amounts of radioactive substances were found in urine samples of all of 10 surveyed children from Fukushima Prefecture in May, where a crippled nuclear power plant is located, a local citizens group and a French nongovernmental organization said Thursday.

David Boilley, president of the Acro radioactivity measuring body, said at a press conference in Tokyo that the results of the survey on 10 boys and girls in Fukushima City aged between 6 and 16 suggest **there is a high possibility that children in and near the city have been exposed to radiation internally.**

The citizens group, the Fukushima Network for Saving Children from Radiation, comprising parents in the prefecture, said the finding is "certainly" due to the nuclear crisis at the Fukushima Daiichi power plant crippled by the March 11 earthquake and tsunami.

The group added it will urge the central and local governments to have all citizens in the prefecture undergo detailed tests soon using whole body counters.

Chief Cabinet Secretary Yukio Edano said later in the day at a press conference, "The government is concerned" about the finding. He added the government wants to obtain detailed results of the survey so they can be thoroughly examined.

Edano said the government also intends to accelerate work to analyze similar surveys conducted by itself and Fukushima prefectural authorities.

According to the urine test, 1.13 becquerels of radioactive cesium-134 per 1 liter of urine, the largest amount for the isotope among the 10 surveyed children, was found from an 8-year-old girl, while the largest amount of cesium-137 at 1.30 becquerels was found in a 7-year-old boy.

Acro also investigated radiation exposure of children who resided near the site of 1986 Chernobyl nuclear disaster.

(Mainichi Japan) June 30, 2011

Circulation cooling system hits another snag

The newly installed reactor-cooling system at the Fukushima Daiichi nuclear power plant has suffered another problem, as its water treatment equipment has stopped.

The system that decontaminates and re-uses radioactive water from the facilities is believed to be the key to the stable cooling of the reactors.

But Tokyo Electric Power Company, or TEPCO, says the decontamination equipment stopped automatically on Thursday afternoon when the alarm went off.

TEPCO says the problem turned out to be a **malfunction of a gas exhaust on a French-made device that removes radioactive material from the water.**

The utility says the device was undergoing engineering work to prevent gases from flowing backward, when the alarm set off.

It is looking into the cause of the malfunction, including a possible link to the engineering work.

TEPCO says it has continued injecting circulated water into the reactors, as it has already treated about 2,000 tons of water to be used for cooling.

Since its start on Monday, the cooling system has experienced a series of problems, including leaky piping.

Thursday, June 30

TEPCO moves low level contaminated water

Workers at TEPCO's Fukushima Daiichi nuclear power plant have started moving low level contaminated water to a giant steel barge for storage.

The transfer from the plant's make-shift tanks started on Thursday afternoon to the barge called **the "mega float."** The barge is attached to a quay on the plant's premises.

The make-shift tanks have been almost full since Wednesday with low-level radioactive water pumped from the basement of the reactor Number 6 turbine building. The water is threatening to damage equipment and gauges and thus hamper cooling efforts.

TEPCO says the water is treated to lower the level of contamination before it is transferred to the barge. The utility also says it will do everything to ensure the stored water doesn't leak into the sea. The utility aims to pump around 8,000 tons of the water into the giant barge over three or four months.

The barge, 136 meters long and 46 meters wide, **can hold a maximum of 10,000 tons of water.**

But the company says it has no final plan to dispose of the water stored in the barge.

Thursday, June 30, 2011

Evacuation de l'eau contaminée présente dans la centrale Fukushima Dai-ichi

Les techniciens de la centrale Fukushima Dai-ichi ont commencé à transvaser de l'eau faiblement contaminée dans une immense barge d'acier.

Le transfert a débuté ce jeudi, entre les citernes improvisées de la centrale et une barge appelée "mega float", amarrée à un quai à même le site.

Depuis mercredi, les citernes de la centrale sont quasiment remplies d'eau faiblement radioactive. Ce liquide, qui provient de la partie inférieure du bâtiment de la turbine du réacteur 6, menace d'endommager l'équipement et les jauges de la centrale, compromettant de fait les travaux de refroidissement.

Selon Tepco, l'eau est partiellement décontaminée avant d'être transvasée vers la barge. L'opérateur de la centrale assure que tout sera mis en oeuvre pour éviter les fuites radioactives dans l'océan.

Workers enter No. 4 reactor building

Tokyo Electric Power Company says debris scattered inside the No. 4 reactor building at the Fukushima Daiichi nuclear plant is posing an obstacle to work to bring the crippled reactor under control.

Workers entered the fifth floor of the building on Wednesday for the first time since an explosion on March 15th.

Photos taken by the workers show that most of the ceiling, except for a small part of the framework, has collapsed. Debris, steel frames, and other various things blown by the force of the explosion are scattered all over the floor.

The radiation level inside the building was less than one millisievert per hour, which TEPCO says is permissible for workers to carry out operations there.

The utility plans to install a circulatory system that will cool and circulate water inside the reactor's spent fuel storage pool. But it says one of the valves necessary to operate the system is covered by debris.

TEPCO says it will consider whether to remove the debris or attempt to work around the debris.

Thursday, June 30, 2011

JUILLET 2011

Toshiba lobbying U.S. to build nuclear waste repository in Mongolia

In this image released Saturday, April 16, 2011, by Tokyo Electric Power Co., top of the container of the nuclear reactor, painted in yellow, of Unit 4 at the Fukushima Dai-ichi Nuclear Plant is observed from its side with a T-Hawk drone Friday, April 15, 2011 in Okuma, Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

TOKYO (Kyodo) -- Toshiba Corp. has lobbied a senior U.S. government official to realize an international nuclear fuel supply scheme that includes the construction of a nuclear waste repository in Mongolia, according to a copy of a letter by Toshiba's president obtained by Kyodo News on Friday.

Norio Sasaki, president of the Japanese electronics giant which has U.S. Westinghouse Electric Co. as a subsidiary, sent the letter dated May 12, 2011, to Deputy Secretary of Energy Daniel Poneman.

The governments of Japan, the United States and Mongolia have already been discussing the scheme, called Comprehensive Fuel Supply, informally, according to an internal Japanese government document dated February 2011, obtained by Kyodo News.

The basic idea of the scheme is to supply countries wishing to introduce nuclear energy with reactors made by U.S., Japanese and other major companies that would use nuclear fuel produced in Mongolia, with the spent fuel returned to the country.

Mongolia is known to hold huge reserves of uranium.

Sasaki said in the letter, "As anti-CFS opposition can be anticipated, it is essential for the Parties to the project to promote closer coordination in order to secure continued progress."

A Toshiba public relations official confirmed that Sasaki had sent the letter to Poneman, while U.S. governmental sources said that the letter was circulated within the administration of U.S. President Barack Obama.

Early in May, the major Japanese daily Mainichi Shimbun carried a story on the project focusing on the possible building of a nuclear waste repository in Mongolia.

"We must recognize that the CFS project has now been publicized around the world," Sasaki's letter said, referring to similar news stories in April in the United States and Mongolia.

In this undated photo released Wednesday, April 13, 2011 by Tokyo Electric Power Co., a standing man is partially seen above an example of the truck used to move spent fuel rods in the pools. Nothing is decided yet but TEPCO told the press at its Tokyo headquarters Wednesday morning that this is one option TEPCO officials are considering to use at the tsunami-stricken Fukushima Dai-ichi nuclear power plant in Okuma town in Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

"Toshiba finds value in CFS because it adds value to Mongolia's natural resources and will contribute to the country's economic growth, while the interim storage solution will bring greater meaning to an international nonproliferation regime," the letter said.

The Obama administration has pushed for an international nuclear supply system as part of his call for a world free of nuclear weapons. Uranium enrichment and the reprocessing of spent fuel can be directed to both military and civilian purposes.

Obama wants to tighten control of these technologies through international supply schemes such as the envisioned CFS because there would be no need for any country that introduces nuclear power generation to develop such technologies and produce its own fuel.

Since the nuclear crisis at the Fukushima Daiichi power plant triggered by the March 11 earthquake and tsunami, antinuclear sentiment has strengthened in Japan and other countries. Some European countries such as Germany and Italy have decided to forgo nuclear power in the future.

In the letter, however, Sasaki said that Japan and the United States should stay the course to promote the CFS even after the Fukushima crisis and "Toshiba's policy of active involvement in CFS remains unchanged."

In February, the Mongolian government sent a delegation to Tokyo for consultations on the CFS project, a Japanese senior official said on the condition of anonymity.

The official criticized Toshiba's lobbying activities, saying, "Even after such a terrible incident in Fukushima, those in the 'nuclear power' inner circle have no feelings of repentance at all." The official also said Sasaki's letter seems to reflect a sense of crisis in the nuclear power industry.

Another Japanese official expressed skepticism regarding the feasibility of the scheme. "How could such a project fly in the future? We have to negotiate with China and Russia if we want to transfer nuclear waste to Mongolia. With respect to transportation, these neighboring countries would have a veto."

In this photo from a footage of a live camera released by Tokyo Electric Power Co. (TEPCO), black smoke billows from the crippled Fukushima No. 1 Nuclear Power Plant in Okumamachi, northeastern Japan, on March 22, 2011. (AP Photo)

There is also skepticism in academic circles in Japan, not only regarding the scheme's technical feasibility but Japan has its own nuclear recycling policy that excludes the option of disposing of spent nuclear fuel from other countries.

"Japan would not accept any spent fuel from any foreign country at the reprocessing plant in Rokkasho (Aomori Prefecture). On the other hand, could we thrust waste from overseas on Mongolia? It would be morally wrong," said Tadahiro Katsuta, associate professor at Meiji University who specializes in nuclear energy policy.

(Mainichi Japan) July 2, 2011

TEPCO: Nuclear fuel pool cooled to stable level

The operator of the crippled Fukushima Daiichi nuclear plant has reported progress in its work to stabilize the facility's spent fuel rods.

Tokyo Electric Power Company says the cooling system that began operating at the No.3 reactor on Thursday has brought the temperature of the nuclear fuel storage pool of the reactor to just below 40 degrees Celsius from the previous level of 62 degrees.

TEPCO says the temperature of the pool was 39.9 degrees as of 5 AM on Saturday.

As cooling has progressed faster than initially expected, TEPCO says the temperature will likely stabilize at around 30 degrees in a few days. The temperature of the spent fuel pool of the No.2 reactor has already declined to that level.

As for the No.1 and No.4 reactors, the utility plans to begin operating cooling systems by the end of this month. Until then, the company needs to inject cooling water on a regular basis.

TEPCO is concerned about possible difficulty in installing the cooling system at the No.4 reactor. A hydrogen explosion in March damaged piping necessary for the system and debris left there is hampering construction work.

The company says there may be a delay in its installation plan.

Saturday, July 02, 2011 13:22 +0900 (JST)

Higher radiation detected on fields than asphalt

A government survey has found higher levels of radiation on fields and forests than on asphalt pavements in towns about 10 kilometers from the Fukushima Daiichi nuclear plant.

The Cabinet Office and the ministry of science monitored radiation for more than 10 days from June 13th at 400 locations in Namie and Tomioka towns, which fall within a 20-kilometer no-entry zone.

The survey centered on JR Namie station, about 8 kilometers from the plant, and JR Tomioka station, about 10 kilometers from the plant. Measurements were made at one centimeter and one meter above the ground.

The highest level in Tomioka was detected on an unpaved road 2 kilometers northwest of the station, where the reading at the one-centimeter point was 39.1 microsieverts per hour.

In Namie Town, 25.4 microsieverts was detected at the one-centimeter point in a forest about one kilometer west of the station.

Readings were generally lower -- around several microsieverts -- on roads and parking lots covered by asphalt and higher on fields and forests.

Radioactive substances are believed to be easily washed away by rain on asphalt but adhere to soil and plants.

The government plans to monitor radiation at more than 3,400 locations in no-entry zones and evacuation advisory zones by the end of August.

Measurements will be taken at gardens of private homes and roof gutters, where radiation tends to be high, as well as roadside ditches.

Saturday, July 02, 2011 11:05 +0900 (JST)

La contamination radioactive plus forte dans les terres et les forêts

Le gouvernement japonais a observé des niveaux de contamination radioactive dans les champs et les forêts, supérieurs à ceux détectés au niveau des rues des villes situées à une dizaine de kilomètres de la

centrale de Fukushima.

Le Bureau du gouvernement et le ministère des Sciences ont effectué des mesures entre le 13 et le 23 juin sur 400 sites des villes de Namie et de Tomioka. Les observations ont été réalisées à un centimètre et à un mètre du sol.

En général, les relevés étaient inférieurs de plusieurs microsieverts au niveau des routes et des parkings à ceux enregistrés dans les champs et les forêts. Les substances radioactives déposées sur le goudron seraient aisément emportées par la pluie. Elles se fixeraient plus fortement sur les terres et les végétaux.

Le gouvernement prévoit d'effectuer d'ici la fin août des mesures à plus de 3400 points des zones interdites et de celles où l'évacuation a été recommandée.

Les opérations de refroidissement de la piscine du réacteur 3 suivent leur cours

Selon l'opérateur de la centrale nucléaire endommagée Fukushima Dai-ichi, les travaux de stabilisation des barres de combustible usagé progressent.

La Compagnie d'électricité de Tokyo, Tepco, a déclaré que le système de refroidissement mis en service au réacteur 3 jeudi a réussi à ramener la température de la piscine de stockage du réacteur de 62 degrés à un peu moins de 40 degrés.

Tepco a indiqué que la température de la piscine était de 39,9 degrés lors d'un relevé effectué samedi à 5h00 du matin.

L'opération de refroidissement ayant été plus rapide que prévu, la compagnie a déclaré que la température devrait se stabiliser à environ 30 degrés dans quelques jours.

La température de la piscine de stockage du réacteur 2 a elle aussi baissé et a atteint le même niveau.

En ce qui concerne les réacteurs 1 et 4, la compagnie prévoit d'entamer les opérations de refroidissement des systèmes avant la fin de ce mois, ce qui sera rendu possible par la mise en route d'une injection régulière d'eau.

TEPCO uses robot to clean No.3 reactor

For the second day in a row, a robot has been sent into one of the damaged reactors at the Fukushima Daiichi nuclear power plant.

It checked radiation levels after a robot on Friday removed radioactive-contaminated dust and rubble from the No. 3 reactor building.

The move was taken before nitrogen is injected into the reactor to prevent another of hydrogen explosion.

Tokyo Electric Power Company has already injected nitrogen into the containment vessels of the No. 1 and 2 reactors. It hopes to complete the injection of nitrogen into the No. 3 reactor by July 17th.

But radiation levels in the No.3 reactor are still too high for workers to safely enter.

On Friday, TEPCO used a US-made robot to begin cleaning inside the building.

The robot removed contaminated dust and rubble near the entrance using a strong vacuum cleaner.

A second robot on Saturday checked the radiation levels. Officials say the levels were lower than before the cleaning.

TEPCO is studying data obtained by the robot.

Sunday, July 03, 2011 03:11 +0900 (JST)

Hose leaking water at Fukushima No.5 reactor

The operator of the troubled Fukushima Daiichi nuclear plant says a hose has been leaking seawater used to cool the No.5 reactor, which is currently in a state of cold shutdown.

Tokyo Electric Power Company, or TEPCO, is set to replace the hose, but will have to suspend the reactor's cooling function to do so. It says this will raise the water temperature, but the reactor will still remain in a state of cold shutdown.

TEPCO says workers patrolling around the No.5 reactor found a hose leaking water on Sunday morning around the outlet of a temporary pump sending seawater into the reactor's cooling system. The company says the polyvinyl chloride hose has a crack about 30 centimeters long and 7 centimeters wide.

TEPCO stopped sending water at around 10 AM to replace the hose. The reactor's cooling system stopped 15 minutes later, meaning its cooling function was temporarily lost.

The water temperature inside the reactor was 43.1 degrees Celsius at 8 AM. TEPCO expects the temperature to rise 2.5 degrees per hour while the cooling function is halted.

The company says that if the replacement work finishes during the night and the cooling system is restarted, the water temperature will not exceed 100 degrees, the level needed to keep the reactor in a state of cold shutdown.

The No.5 reactor was hit by a pump failure on May 29th, when a delay in recovery briefly sent the water temperature to 94.8 degrees.

Sunday, July 03, 2011 12:58 +0900 (JST)

Cooling resumes at Fukushima No.5 reactor

The operator of the troubled Fukushima Daiichi nuclear plant says cooling functions have resumed at the No.5 reactor.

On Sunday morning, Tokyo Electric Power Company, or TEPCO, found seawater was leaking from a crack in a hose around the outlet of a temporary pump sending seawater into the reactor's cooling system.

The company says the polyvinyl chloride hose had a hole about 30 centimeters long and 7 centimeters wide.

The utility stopped sending water at about 10AM to replace the hose. The cooling system halted 15 minutes later and the reactor's cooling function was temporarily lost.

Following the replacement, **the cooling system resumed operation 3-and-a half hours later.**

The water temperature at the reactor rose by some 5 degrees Celsius to **47.7 degrees Celsius** during the suspension. **But the reactor is said to have remained in a state of cold shutdown.**

TEPCO says the crack happened because the pleated flexible tube was constantly moved by tides and had come under hydraulic pressure.

The firm is considering preventive measures to avoid similar incidents in the future.

Sunday, July 03, 2011 16:58 +0900 (JST)

TEPCO improves circulation cooling system

The operator of the troubled Fukushima Daiichi Nuclear Plant says **the reactor cooling system is now fully recycling its water.**

Tokyo Electric Power Company said the system no longer requires fresh water input, and no contaminated water is being released.

Previously, the system required 2 to 3 tons of fresh water per hour. **[wasn't it much more than that ?]**

Water recycling resumed on Saturday evening after being suspended while the plant's operator installed stronger piping to prevent leaks.

Tokyo Electric Power Company had switched off the plant's cooling system for a day and a half after a series of problems.

The operation started a week ago, but was twice halted because of leaks. A water-decontamination device in the system also had to be shut down due to human error.

TEPCO cited a lack of preparation due to the speed of installing the system, which consists of Japanese and foreign devices.

The utility has set a target of July 17th to complete the first stage of its plan to bring the facility under control.

Sunday, July 03, 2011 07:56 +0900 (JST)

Preparations underway for nitrogen injection

Preparations are underway to start injecting nitrogen into the Number 3 reactor at the Fukushima Daiichi nuclear plant **by July 17th**.

Tokyo Electric Power Company, which operates the plant, had planned to start injecting nitrogen into the first 3 reactors by that date **to prevent hydrogen explosions**.

But high levels of radiation on the floor of the Number 3 reactor building, caused by contaminated dust spread by the previous explosion, have delayed the start of the work.

The utility started cleaning the floor with a robot on Friday, but radiation levels remained **between 50 to 186 millisieverts per hour as of Saturday**, although they fell at 9 of the 16 locations measured.

The company began covering the floor with steel sheets on Sunday to reduce the radiation levels by two-thirds. [??]

The utility will investigate the piping to be used for the injection on Wednesday, and start connecting the pipes on Friday, so the injection can begin by July 17th, as scheduled.

Nuclear Crisis Minister Goshi Hosono said he wants to consider lifting the order to prepare for the emergency evacuation of certain areas after confirming that another hydrogen explosion will not occur.

All eyes are on whether the injection can be started as planned.

Sunday, July 03, 2011 23:21 +0900 (JST)

New nuke minister inspects radiation monitoring

Japan's new nuclear crisis minister has inspected the monitoring of radiation levels in the evacuation zone around the Fukushima Daiichi nuclear power plant.

Goshi Hosono on Sunday visited Iitate Village in Fukushima Prefecture, more than 30 kilometers northwest of the troubled plant.

Hosono, who assumed the new position just last week, was guided to see how the Science Ministry carries out the survey.

He saw the figure was 13.9 microsieverts per hour, far exceeding the legal limit forcing the evacuation of local residents.

He was told that the **data are collected at one meter above ground level**. He asked officials to keep as

accurate a record as possible for the safety of the people.

Hosono said after the inspection that the collected data is also important to create a framework for finding ways to remove radioactive materials in the future.

He said he hopes the close monitoring will continue, adding that he wants to consider the possibility of having people return home as soon as possible.

Sunday, July 03, 2011 16:58 +0900 (JST)

Tsuruga reactor not equipped with vent to relieve pressure

A photograph shows the Tsuruga Nuclear Power Plant in Tsuruga, Fukui Prefecture.(Mainichi)

TOKYO (Kyodo) -- **The No. 1 reactor at the Tsuruga nuclear power plant in Fukui Prefecture is not equipped with a vent to discharge steam from the reactor container to relieve inside pressure in case of emergency**, sources close to the matter said Sunday.

Among 30 boiling-water reactors in Japan, the Tsuruga reactor is the only one that lacks the system as its operator, Japan Atomic Power Co., believed it is less likely the container would be damaged due to pressure buildup, and thus setting up of the system had low priority.

However, the company decided to install the system during ongoing regular checkups as venting has been needed to put crippled reactors at the Fukushima Daiichi nuclear power plant under control, according to the sources.

It has been estimated that the probability that pressure increase would damage the reactor is around 1 percent, but that at the No. 1 reactor at the Fukushima plant was also 1 percent, leading the company to install the system, according to the company.

The No. 1 reactor at the Tsuruga plant, the oldest reactor in Japan, started operations in 1970 and has been undergoing a 14-month inspection since January.

The company announced in 2002 that it would suspend operation of the reactor in 2010 and eventually decommission it, but it later decided to continue operations through 2016.

(Mainichi Japan) July 4, 2011

Hoses at Fukushima to be checked

Tokyo Electric Power Company, or TEPCO, is set to replace leaky plastic hoses that brought cooling to a halt at the Number 5 reactor at the Fukushima Daiichi nuclear plant.

TEPCO is now searching for potential leaks and will replace these hoses. A large number of the polyvinyl chloride hoses are being used in the reactor's heat removal system.

TEPCO found water leaking from a large crack in a hose around the outlet of a temporary pump sending seawater into the Number 5 reactor's cooling system on Sunday. The cooling system was stopped for 3-and-a-half hours to replace the hose.

The operator says the hose cracked because it was bent at an acute angle and was under pressure.

The company fears other hoses may crack and will search for possible trouble and replace them.

TEPCO adds that **no replacement is required for hoses that transfer highly radioactive water because they are not bent at extreme angles.**

Monday, July 04, 2011 06:15 +0900 (JST)

Lack of responsibility between state, TEPCO for nuclear disaster has deep roots

Is compensation over ongoing nuclear disaster the responsibility of Tokyo Electric Power Co. (TEPCO) which operates the stricken nuclear power plant, or the national government?

According to a new nuclear disaster compensation bill that has been submitted by the Cabinet and is slated for deliberations in the Diet this week, the answer is this: "TEPCO, of course, but the government will provide TEPCO with some assistance." The outlook for the bill's passage remains uncertain.

The lacking presence of this bill and the challenges that lie ahead of it are symbolic of Japan's uneasiness stuck between the promotion of nuclear power and its elimination.

If nuclear power is to be given another chance, it is obvious that the only viable way would be for the national government to take over its promotion. The government, however, has yet to clarify its stand. The proposed bill ambiguously states that the government will "aid" the power company. It's an

equivocal stopgap measure that neither pardons nor kills off TEPCO, and can be interpreted as the willingness or lack thereof on the part of the government to actually shell out any money. This sums up the essence of the nuclear disaster compensation bill.

There was a tussle within the Cabinet prior to the creation of the bill, between 72-year-old Minister of State for Economic and Fiscal Policy Kaoru Yosano and Chief Cabinet Secretary Yukio Edano, 47.

Article 3 of the existing law on nuclear damage compensation states: "When nuclear damage has occurred owing to or during the operation of a reactor, etc., the nuclear operator who is engaged in the operation of the reactor, etc. on that occasion shall be liable for the damage." However, it goes on to make an exception "for the case where the damage is caused by an extraordinarily grave natural disaster or by a serious social disturbance.

Yosano argued that the latest case constituted "obvious exemption (from liability)," to which Edano objected: "Unless we make law revisions, we cannot reach that conclusion about the situation."

Yosano is a favored disciple of former Prime Minister Yasuhiro Nakasone, a pioneering figure in Japan's nuclear power policy. After graduating from college, Yosano joined the newly established Japan Atomic Power Co. on Nakasone's recommendation, where he dealt with insurance. Edano, meanwhile, is a lawyer. This makes the dispute one between two experts.

In the end, Edano won out. This meant that TEPCO, which faces a massive excess of debts, will not be able to newly procure funds, threatening the stable supply of electricity. This was what led the Cabinet to concoct the new nuclear disaster compensation bill.

Demonstrators parade past the headquarters of Tokyo Electric Power Co. (TEPCO) during their anti-nuclear power protest, in Tokyo, Sunday, May 1, 2011. (AP Photo/Shizuo Kambayashi)

Asked why Yosano buried the hatchet, he responded: "I was told by the Finance Ministry that the national government does not compensate disaster victims, and if TEPCO were to be exempted from paying restitution, then there would be no one to act as the agent of compensation."

The conflict has deep roots. I found through some research that the Kishi Cabinet, in stepping up its efforts toward the peaceful use of nuclear power, established a team of experts in 1958 led by renowned civil-law scholar Sakae Wagatsuma, to advise the government on the issue of compensation in the case of a nuclear disaster.

The team, which looked into how the issue of compensation was being handled in industrialized nations, submitted a report stating that state compensation payments were necessary in worst-case scenarios. However, in the process of deliberating and passing the current law on nuclear damage compensation, which took the experts' recommendations into account and went into effect in 1961, state compensation was effectively eliminated.

A section chief at the then Ministry of International Trade and Industry who worked on the bill revealed in a roundtable discussion that the watering down of state liability had been the wish of the Ministry of Finance at the time. In the discussion, featured in the Oct. 15, 1961 issue of legal journal Jurist, the section chief said that the Finance Ministry had brushed off possible stipulation of state redress, declaring that "the state had never assumed direct responsibility for victims since the Meiji era."

Wagatsuma, who moderated the roundtable discussion, expressed regret upon hearing what had happened behind the law-making scenes. "To say that because the operator has no responsibility, neither does the state, and to deal with nuclear disasters in the same way as natural disasters like the (1959) Isewan Typhoon (Typhoon Vera) ... this is such a shame. If things were going to turn out this way, I feel we should have given things more thought."

As it turns out, the irresponsibility of the government and TEPCO in the latest nuclear disaster has its roots in events that transpired half a century ago. Nuclear power plants were still in their planning stages at the time, but today we live in a nuclear-dependent society. And still, the avoidance of responsibility continues, and it is by extension that the latest nuclear disaster compensation bill has emerged.

The three criteria that Prime Minister Naoto Kan has listed as conditions for his resignation are the passage of the second supplementary budget for fiscal 2011, a special government bond bill and a renewable energy bill. The new nuclear disaster compensation bill didn't make the cut. This points to Kan's glaring lack of awareness regarding the significance of the problem. I question his sensibilities. (By Takao Yamada, Expert Senior Writer)

(Mainichi Japan) July 4, 2011

Work underway for nitrogen injection

Work is underway at the damaged nuclear power plant in Fukushima to reduce radiation levels in the Number 3 reactor container. The move is necessary before nitrogen gas can be pumped in to prevent a hydrogen explosion.

According to Tokyo Electric Power Company's schedule to stabilize the plant, the utility needs to inject nitrogen into the containers of the first 3 reactors by July 17th. Nitrogen has already been injected into the Number 1 and 2 reactor containers.

On Friday, a US-made robot began clearing contaminated dust and debris from the floors of the Number 3 reactor building. However, radiation levels inside the building are still high with **readings of between 50 and 186 millisieverts per hour.**

The radiation levels need to be reduced to one-third before workers are able to begin the nitrogen injection.

On Sunday, more than 50 sheets made of steel were laid on the floor. Work continues on Monday to fill the gaps between the steel sheets.

TEPCO plans to start connecting the pipes to inject the nitrogen on Friday and hopes to complete the nitrogen injection by July 17th. Cooling the reactors and preventing more hydrogen blasts are the top priorities in TEPCO's plan to stabilize the plant.

The minister in charge of the nuclear disaster, Goshi Hosono, says **once the government is able to verify that the blast prevention measures are in place, it will consider lifting an evacuation advisory for certain areas 20 to 30 kilometers from the plant.**

Monday, July 04, 2011 13:42 +0900 (JST)

Robot to gauge radiation in No.3 reactor

The operator of the crippled Fukushima Daiichi nuclear plant says it will send a robot inside the No.3 reactor to measure radiation and determine if it is safe to begin injecting nitrogen.

Tokyo Electric Power Company is rushing to implement the procedure, which has already been carried out in the No.1 and 2 reactors to prevent further hydrogen explosions.

High levels of radiation are hampering work inside the building housing the reactor. TEPCO workers on Monday covered parts of the floor with steel plates to block the radiation.

TEPCO says the remote-controlled robot is equipped with a special camera that shows radiation in different colors.

The firm plans to begin the operation on Wednesday after preparations on Tuesday. Once it has confirmed that radiation is falling, **it will inspect pipes that will be used to inject nitrogen.** It says if there are no problems, it will begin the injection **before July 17.**

Nuclear crisis minister Goshi Hosono said he wants to shrink the evacuation zone around the plant by that date, so attention is focused whether the plant operator can implement the operation as scheduled.

Tuesday, July 05, 2011 13:37 +0900 (JST)

Water flow falls at No.1 reactor, but restored

The volume of cooling water flowing into the No.1 reactor of the Fukushima Daiichi nuclear plant fell on Monday, forcing workers to inject additional water.

A cooling system is in place at the number 1, 2 and 3 reactors. The system injects 3.7 tons of water every hour into the No.1 reactor.

Tokyo Electric Power Company says the reactor's water flow began to decrease gradually around 9 PM on Sunday night. By 8:13 AM on Monday, only about 3 tons of water was flowing into the No. 1 reactor, setting off an alarm.

Workers immediately began injecting double the usual amount of water. They managed to restore normal water flow in the reactor before 9 AM.

TEPCO says there was no change in temperature or pressure in the No.1 reactor.

The utility says some kind of debris may have clogged the hoses, reducing the water flow, and that it is checking to see how the failure occurred.

Monday, July 04, 2011 17:29 +0900 (JST)

45% of kids in Fukushima survey had thyroid exposure to radiation

Teachers see children onto a bus after the end of lessons at Oguni Elementary School in Date, Fukushima Prefecture, on June 30. The school has instructed children to wear masks, hats and long sleeves to protect them from radioactive materials. (Mainichi)

TOKYO (Kyodo) -- Around 45 percent of children in Fukushima Prefecture surveyed by the local and central governments in late March experienced thyroid exposure to radiation, although in all cases in trace amounts that did not warrant further examination, officials of the Nuclear Safety Commission said Tuesday.

The survey was conducted on 1,080 children aged 0 to 15 in Iwaki, Kawamata and Iitate on March 26-30 in light of radiation leakages from the Fukushima Daiichi nuclear power plant crippled after the March 11 earthquake and tsunami disaster.

Separately, a survey of soil at four locations in the city of Fukushima on June 26 found that all samples were contaminated with radioactive cesium, measuring 16,000 to 46,000 becquerels per kilogram and exceeding the legal limit of 10,000 becquerels per kg, citizens groups involved said Tuesday.

The city, about 60 kilometers northwest of the crippled plant, does not fall within the 20-km no-entry zone or nearby evacuation areas.

One location registered as much as 931,000 becquerels per square meter, **surpassing the 555,000 becquerels per sq meter limit for compulsory resettlement in the 1986 Chernobyl nuclear accident.** Samples from the other three locations measured between 326,000 and 384,000 becquerels per sq meter.

Among children who tested positive for thyroid exposure, the amounts measured 0.04 microsieverts per hour or less in most cases. The largest exposure was 0.1 microsieverts per hour, equivalent to a yearly dose of 50 millisieverts for a 1-year-old.

None of those surveyed was exposed to over 0.2 microsieverts per hour, the government's benchmark for conducting more detailed examinations, according to the officials.

Babies and young children are at highest risk of developing thyroid cancer after exposure to radioactive iodine released into the atmosphere in nuclear accidents. In the case of Chernobyl, most victims who developed the cancer in following years had been babies or young children living in the affected regions at the time of the accident.

(Mainichi Japan) July 5, 2011

4 local governments seek to scrap nuclear plants

An NHK survey of local governments with nuclear power plants has found that 4 of 28 respondents are ready to break with nuclear energy.

Last week, NHK asked local governments with nuclear plants, except those in Fukushima Prefecture, how their thinking about the plants has changed since the Fukushima Daiichi crisis began.

Of the 28 prefectures and municipalities that responded, 15 said they could not make an immediate decision on whether to pursue closure of their plants.

Five municipalities said they would not seek to have their plants scrapped, because nuclear power remains a vital source of energy.

Shizuoka Prefecture, however, said it wants to immediately launch a campaign to have its plants decommissioned.

Three other local governments said they hope to launch such campaigns in the near future.

Shizuoka Governor Heita Kawakatsu said the nuclear crisis in Fukushima has underscored the need for a fundamental review of Japan's energy policy. He said the country must make efforts to shift to new sources of energy.

Mayor Tatsuya Murakami of Tokai Village, where a criticality accident occurred in 1999, said it's become impossible to predict the extent of impact a nuclear disaster would have.

He said Japan should take the global initiative in moving toward the abandonment of nuclear energy.

Tuesday, July 05, 2011 19:08 +0900 (JST)

Emergency generators faulty at 2 nuclear plants

Japan's Nuclear and Industrial Safety Agency says the defective components discovered in emergency generators at 2 nuclear power plants have been replaced.

Agency inspections found faulty parts in the back-up generators for the No. 1 reactor at Hokuriku Electric Power Company's Shika plant, and the No. 1 reactor at Kansai Electric Power Company's Mihama plant.

The inspections followed the discovery of defective parts in an emergency generator for a fast-breeder reactor in Tsuruga City, on the Japan Sea coast.

Last December, a crack in a component of the cylinder of the generator for the "Monju" reactor caused a malfunction.

The crack was blamed on weakness of the component due to its lead content having been wrongly mixed with other metals in the manufacturing stage.

Tuesday, July 05, 2011 17:53 +0900 (JST)

Japan to conduct nuclear plant 'stress tests' amid safety concerns

(Mainichi Japan) July 6, 2011

In this June 12, 2011 photo released on July 5, 2011 by Tokyo Electric Power Co., masked workers in protective outfits prepare to drop one of sliding concrete slabs into a slit of the upper part of the sluice screen for Unit 2 reactor at the tsunami-crippled Fukushima Dai-ichi nuclear power plant in Okuma, Fukushima Prefecture, northeastern Japan, in their effort to decrease the leak of radiation contaminated water to the ocean. (AP Photo/Tokyo Electric Power Co.)

TOKYO (Kyodo) -- Japan plans to conduct safety assessments called "stress tests" on all its nuclear power plants to allay heightened public concerns over their safety, industry minister Banri Kaieda said Wednesday, as the government struggles to resume operation of reactors that are suspended for regular checkups.

In a sign such stress tests could further delay the resumption and possibly deepen the country's power shortage problem, Saga Gov. Yasushi Furukawa said after Kaieda's announcement that "it's appropriate to wait for the test results" before deciding whether to approve the restart of two reactors at the Genkai plant in the prefecture.

None of the reactors in the country has resumed operations since the nuclear crisis at the Fukushima Daiichi power plant.

The Nos. 2 and 3 reactors at the four-reactor Genkai plant were initially expected to have been reactivated by now, but their resumption has been postponed following the crisis.

In Tokyo, Kaieda told reporters that the safety of the Genkai plant has been confirmed through safety measures taken in the wake of the Fukushima emergency, but said there is a need to quickly carry out stress tests like those conducted by the European Union to offer a "sense of assurance" to local residents.

He also said he would like to make sure that no problems occur regarding stable supply of electricity.

Furukawa is scheduled to meet with Chief Cabinet Secretary Yukio Edano in Tokyo on Thursday about the Genkai plant issue, the Saga prefectural government said.

Under the stress tests, plant operators are expected to assess how far nuclear reactors can withstand major earthquakes and tsunamis that have an impact going beyond expectations, and find the weak points, according to officials of the government's nuclear safety agency.

While details have yet to be decided, it may take several months to finish the tests. The European Union started similar stress tests in June.

The need for stress tests on nuclear power plants was touched on during a ministerial meeting of the International Atomic Energy Agency on nuclear safety in late June, which was convened in the wake of the crisis at the Fukushima plant operated by Tokyo Electric Power Co.

The Fukushima complex, which was only designed to withstand tsunami waves of a maximum of 5.7 meters high, lost nearly all of its power sources, and thus the cooling functions of many reactors, after being hit by a magnitude 9.0 earthquake and tsunamis more than 14 meters high on March 11.

Based on lessons learned from the crisis, the Economy, Trade and Industry Ministry announced June 18 that utilities have appropriately implemented measures to enable their nuclear power plants to handle severe accidents, such as steps to prevent hydrogen explosions.

Kaieda visited Saga Prefecture in late June to seek approval for the resumption of the Genkai reactors, saying their safety has been confirmed through such safety measures.

The head of the local municipality hosting the plant agreed on the resumption, but adjacent municipalities and the prefectural assembly are reluctant about giving the green light.

Although Saga Gov. Furukawa was expected to make a decision on the issue in mid-July, he said the plan "completely blew up" after the government announced about the stress tests.

TEPCO says reactor cooling on target at 80 percent

Tokyo Electric Power Company says its system for recycling highly-radioactive water at the Fukushima Daiichi nuclear plant is operating slightly below target at 80 percent capacity.

The company says it will try to stabilize operation at 80 percent, rather than raising the target to 90 percent as planned.

The process of decontaminating and re-circulating wastewater to cool the damaged reactors began on June 27th.

It was disrupted 3 times last week, partly due to human error. Filtering of wastewater was just 55 percent of capacity at the start. The power company must stabilize the cooling system to get the nuclear crisis under control.

Wednesday, July 06, 2011 12:41 +0900 (JST)

Radioactive strontium to be closely monitored

Japan's science and technology ministry says tests have found no radioactive strontium in the seabed off the northern Pacific coast.

The test follows last month's detection of the radioactive material in the seabed near the damaged Fukushima Daiichi nuclear plant. The operator of the plant took samples 3 kilometers off the coast at 2 locations -- 20 kilometers south and north of the plant. Radioactive strontium can cause cancer as it accumulates in bones if inhaled.

No radioactive strontium was found this time in samples taken at 6 locations between 10 and 30 kilometers off a section of the Pacific coast that includes Fukushima Prefecture and two prefectures to the south and north.

The Nuclear Safety Commission, an independent body advising the ministry, says more evidence is needed to prove that no strontium has reached these locations.

The current system cannot detect amounts below 0.8 becquerels of strontium per kilogram of soil. It has advised the ministry to use a method that can detect smaller amounts of the radioactive substance.

The fisheries ministry is also testing marine products caught off Ibaraki and Chiba prefectures, near Tokyo, but found no strontium.

Wednesday, July 06, 2011 08:33 +0900 (JST)

Parts of reactor cover arriving at Fukushima plant

Sections for covers that will contain radioactive materials released from the damaged reactors at the Fukushima Daiichi plant have begun arriving at the site.

The covers will be installed at the No.1, 3 and 4 reactors. Buildings housing these reactors sustained severe damage from hydrogen blasts triggered by the March 11th earthquake and tsunami.

Pillars, beams and other parts are being pre-assembled at a port 50 kilometers away from the plant.

The concrete bases of the structure will be delivered on Wednesday with more sections arriving from mid-July.

The operator of the plant, Tokyo Electric Power Company, says it hopes to complete assembly work by late September using a crane with a 140-meter long arm.

Reducing radiation released from the reactor buildings is crucial to getting the crisis under control.

This month, TEPCO will estimate the current amount of radiation released from the reactors. The figures will be used as a reference to gauge the effectiveness of the covers when they are installed.

Wednesday, July 06, 2011 07:11 +0900 (JST)

[What happened to the idea of shielding the reactors from underneath too, to protect underground water?]

Microbes used to remove cesium in water and soil

Japanese researchers have found that microbes could help remove cesium from water and soil, raising hopes for their use in decontamination efforts around the Fukushima Daiichi nuclear plant.

A team led by Professor Ken Sasaki of Hiroshima Kokusai Gakuin University has for 10 years been studying **ways to remove metals using microbes called phototrophic bacteria.**

Such removal is possible because negative ions on the microbes attract positively charged metals.

The team recently experimented with 2.5 grams of cesium mixed in water, and about 90 grams of microbes.

The cesium dropped to one-twelfth its original density in 24 hours, and was gone by the third day. The same effect was confirmed in soil.

The team says the microbes could very likely also remove radioactive cesium from around the plant, and plans to test soil and water in Fukushima Prefecture to put the method into practical use.

Wednesday, July 06, 2011 16:28 +0900 (JST)

Did earthquake cause meltdown at Fukushima Daiichi even before tsunami hit? (Beyond Nuclear)

[The Atlantic Wire](#), in an article entitled "Meltdown: What Really Happened at Fukushima?" by Jake Adelstein and David McNeill, reports -- based on interviews with eyewitnesses, as well as a careful review of the catastrophe's timeline and even documented admissions made by Tokyo Electric Power Company itself -- that major damage to piping and other safety significant structures at Fukushima Daiichi Unit 1 -- the oldest reactor at the site -- may very well have begun the first meltdown, even before the tsunami hit. The article reports:

"The reason for official reluctance to admit that the earthquake did direct structural damage to reactor one is obvious. Katsunobu Onda, author of *TEPCO: The Dark Empire*, who sounded the alarm about the firm in his 2007 book explains it this way: **'If TEPCO and the government of Japan admit an earthquake can do direct damage to the reactor, this raises suspicions about the safety of every reactor they run.** They are using a number of antiquated reactors that have the same systematic problems, the same wear and tear on the piping.' "

The article adds:

"On May 15, TEPCO went some way toward admitting at least some of these claims in a report called 'Reactor Core Status of Fukushima Daiichi Nuclear Power Station Unit One.' The report said there might have been pre-tsunami damage to key facilities including pipes. **'This means that assurances from the industry in Japan and overseas that the reactors were robust is now blown apart,'** said Shaun Burnie,

an independent nuclear waste consultant. **'It raises fundamental questions on all reactors in high seismic risk areas.'** "

Tsunamis are even more rare than already rare earthquakes. Thus, tsunami risks -- including to U.S. reactors -- can more easily be portrayed by the nuclear establishment in industry and government as exceedingly improbable -- even though a radioactively catastrophic one has just happened in Japan. Not only Tepco and the Japanese federal government were quick to obscure earthquake damage at Fukushima Daiichi, focusing attention on the tsunami's impact instead. Exelon Nuclear's CEO, John Rowe, who "serves" on President Obama's and Energy Secretary Chu's "Blue Ribbon Commission on America's Nuclear Future," was quick to downplay the earthquake's impact at Fukushima, instead highlighting the tsunami. [An Exelon statement dated March 14th began:](#)

"Exelon is closely monitoring the situation in Japan as it continues to unfold. While there is still a great deal we don't know, from all information the company received so far, it appears that the damage to the Japanese plants was primarily related to the tsunami, not the earthquake."

A common "red herring" refrain of the U.S. nuclear industry since March 11th is that tsunamis are impossible at the many inland reactors across the U.S., while largely or entirely ignoring earthquake risks themselves, as well as other pathways (tornadoes, hurricanes, floods, fires, power outages, mechanical failure, human error, intentional attack, etc.) that could plunge reactors into station blackout, followed within hours by core meltdown and days by high-level radioactive waste storage pool fires.

Utility admits to dishonest e-mails on restart

It has come to light that the operator of the Genkai nuclear power plant had requested its staff and affiliates to send e-mails supporting the restart of the reactors to a meeting to explain the government's safety measures.

On June 26th, the government held a meeting in Saga City to answer questions from residents in preparation for the resumption of the operation of the nuclear reactors.

The meeting was shown live by a cable TV station and via the Internet, and viewers were invited to send in their opinions by e-mail or fax.

On Wednesday, Kyushu Electric Power Company President Toshio Manabe revealed that 4 days before the meeting, its head office instructed some company members and 4 affiliated firms to send in e-mails expressing support for restarting the reactors.

Manabe offered an apology, saying that **his company's action undermined the credibility of the meeting.**

He said he does not know how many e-mails were sent.

Manabe also said the company hoped to help deepen residents' understanding by stating its opinion as the plant operator.

He said he is responsible for the inappropriate act, but added that he is not considering stepping down as president.

Industry minister Banri Kaieda issued a statement saying it is outrageous to do such a thing and the incident undermines the aim of the meeting.

Thursday, July 07, 2011 02:57 +0900 (JST)

Kyushu Electric sought to distort local views over reactors restart

FUKUOKA (Kyodo) -- Kyushu Electric Power Co. said Wednesday that companies linked to the utility ordered their employees to post online comments in favor of the resumption of the utility's two nuclear reactors for a local cable television program aimed at seeking support for the resumption.

Industry minister Banri Kaieda said in a statement that such conduct by the employees, acting as general citizens, fundamentally undermined the purpose of the industry ministry-organized event to respond to their candid questions.

"This is outrageous," Kaieda said, adding that Kyushu Electric President Toshio Manabe was strongly warned over the issue.

The two nuclear reactors at the Genkai power plant in Saga Prefecture are drawing attention because they are yet to restart in the wake of the March nuclear crisis, even though their regular checkups were initially expected to have finished by now.

Manabe apologized over the matter during a press conference at the company's headquarters in the city of Fukuoka and explained that the act was intended to stress the importance of nuclear power to the local people, but denied his involvement.

The program was shot and aired at a cable TV studio in the city of Saga on June 26 and featured government officials and local residents. It was also aired via the Internet.

According to Kyushu Electric, one of its male employees sent e-mails on June 22 to seven people at three Kyushu Electric offices and the utility's four subsidiaries, asking them to post comments supportive of the resumption of the reactors.

The program was the first attempt by the central government to brief residents of municipalities that host nuclear power plants on nuclear safety measures.

(Mainichi Japan) July 7, 2011

Wastewater filters not working to capacity

The operator of the crippled Fukushima Daiichi nuclear plant says it will look into **why the filters in its cooling system to recycle radioactive wastewater are working at a rate far below the initial estimate.**

Tokyo Electric Power Company says about 14,670 tons of wastewater had been decontaminated as of 10:00 AM on Wednesday.

The filters were processing 43 tons of wastewater per hour, which is 14 percent below the initial estimate of 50 tons per hour.

This has resulted in the filters working at just 76 percent capacity over the week through Tuesday. That is 4 percentage points below the initial target.

Recycling of wastewater is key to cooling the reactors.

But if the process takes too much time, the utility's schedule for bringing the nuclear crisis under control could be delayed.

Wednesday, July 06, 2011 19:15 +0900 (JST)

Reactor cooling to be accelerated in August

The operator of the Fukushima Daiichi nuclear plant says a new cooling system is now working well so it will accelerate the cooling of the plant's reactors in August.

The system, which recycles decontaminated radioactive wastewater, suffered a series of problems at its launch in late June.

But Tokyo Electric Power Company says it has been working almost as planned since the start of this month.

The utility says that with radioactive water still leaking from 3 reactors, it had to limit the amount of wastewater used in the system. The leaks mean that the level of toxic water already accumulated is not decreasing.

The utility says if the water decontaminator keeps working properly, the water level will drop over one meter below the risk of overflowing by next month.

That in turn would allow it to ease restrictions on the amount of water used to cool the reactors.

But the company is still concerned about the extent of damage to the reactor containment vessels. Injecting more water into the damaged vessels could release more radioactive steam into the environment.

Thursday, July 07, 2011 07:57 +0900 (JST)

Nitrogen injection could be delayed at Fukushima

The operator of the troubled Fukushima Daiichi power plant is having trouble injecting nitrogen gas into one of the reactors to prevent a hydrogen explosion.

Tokyo Electric Power Company on Wednesday examined the **No.3 reactor** to see if it can connect injection pipes to the containment vessel.

A camera-mounted robot was used for the operation because high radioactive levels are preventing workers from remaining in the reactor building for long periods.

But TEPCO failed to confirm the situation because **the robot couldn't reach the necessary part of the reactor.**

Radiation levels as high as about 50 millisieverts per hour were registered in the area.

The reading means a worker would be exposed to radiation on par with the government-set 250-millisievert safety limit in 5 hours.

TEPCO is now considering sending personnel or a robot into the reactor building to conduct another survey. The new survey would happen on Friday at the earliest.

There is a growing likelihood that the planned nitrogen injection will be delayed.

Thursday, July 07, 2011 12:58 +0900 (JST)

Japan's nuclear crisis affects farm exports

Japan's exports of farm, marine and forest products in May posted a year-on-year plunge of more than 16 percent, due to the nuclear crisis at the Fukushima Daiichi power plant.

The Agriculture, Forestry and Fisheries Ministry says exports in the 3 sectors dropped 16.6 percent from the same month last year to 378 million dollars. That's the second straight month of a drop of more than 10 percent.

The ministry attributes the plunge to restrictions imposed by 41 countries and territories on imports of foodstuffs from Japan since the nuclear crisis began in March.

Total food exports to China dropped 48.4 percent, to South Korea 40.4 percent, and to Hong Kong 22.3 percent.

Shipments of salmon, trout, bonito and other fish to mainly Asian countries plunged 29.6 percent while shipments of apples, yams and other agricultural products dropped 9.8 percent.

The Ministry says the discharge of radioactive contaminated water into the ocean after the nuclear

accident prompted many countries to restrict fish imports from Japan.

The Ministry says it will further urge those countries to make decisions based on scientific evidence.

Thursday, July 07, 2011 02:57 +0900 (JST)

Animals suffer the effects of Fukushima nuclear devastation

The Fukushima nuclear accident in Japan has taken a massive toll on animals. The fate of wildlife is largely unknown, but domestic pets and livestock continue to suffer.

[Livestock](#) were forcibly abandoned and left behind to starve. [Cows contaminated](#) with cesium five times the permissible level have been slaughtered. Buried in the ground, their radioactive carcasses will continue to contaminate the land for decades if Chernobyl is any indication.

[Family pets](#) were left behind, tied, abandoned in homes, or left to roam the streets in search of food. Their owners were forbidden to return or were allowed to make brief visits to feed them, often too late.

A [rabbit born without ears](#) is stoking fears of birth defects and genetic damage among humans while whales have been caught that are found to be [contaminated](#) with radioactive cesium.

In the event of US reactor accidents, citizens are encouraged to evacuate with their pets. However, evacuation shelters and most hotels do not allow animals. Livestock, of course, cannot be evacuated.

Sign our petition to [protect animals](#) from nuclear devastation by supporting safer renewable energy.

De Beyond Nuclear

TEPCO temporarily halts cooling Fukushima Daiichi reactor

TOKYO (Kyodo) -- Tokyo Electric Power Co. said Thursday that it stopped the cooling system for a reactor at the Fukushima Daiichi power plant in Fukushima Prefecture for three and a half hours **due to an electrical system problem**.

Cooling operations were suspended for the No. 1 reactor and an adjacent pool for spent nuclear fuel from around 5:30 p.m. to shortly past 9 p.m. while the operator, known as TEPCO, looked into why sparks came from a power panel at a building adjacent to that housing the reactor.

Temperatures for the reactor and the fuel storage pool are believed to have risen slightly from about 25 C to 35 C and from 26 C to 27 C, respectively, during the suspension.

The reactor and the pool must be kept cooled because nuclear fuel inside them emits heat as it decays, even though the reactor has gone offline and has been brought into a stable condition called "cold shutdown" following the March earthquake and tsunami.

The other three reactors at the Fukushima Daiichi plant, located to the south of the crisis-hit Fukushima Daiichi nuclear power complex, have also been in cold shutdown-mode since the disasters.

A plant worker found sparks coming out of a power panel in the basement of the No. 1 reactor's adjoining facility shortly after 2 p.m., prompting the company to cut power to the facility so that it could be inspected, TEPCO said.

The reactor has two sets of cooling systems for sustaining cold shutdown, but one of them has remained crippled since the tsunami in March.

(Mainichi Japan) July 8, 2011

Nuke plant equipment fails quake-resistance check

The Japanese government has found that electrical equipment at a nuclear power plant in eastern Japan does not meet earthquake-resistance standards.

The Nuclear and Industrial Safety Agency inspected nuclear power plants nationwide after the March 11th earthquake damaged equipment at the Fukushima Daiichi nuclear power plant. The plant was unable to cool its reactors after losing power.

The agency found that the level of quake-resistance of the electrical equipment at Tokai Daini nuclear power plant in Ibaraki Prefecture was below the standard set by power companies.

The Tokai Daini plant is currently undergoing regular inspections. The operator plans to strengthen the quake-resistance of its equipment during the inspection period.

The agency says the electrical equipment in other nuclear power plants are up to standards.

Once it identifies what caused the damage to the equipment at the Fukushima Daiichi plant, the agency plans to re-examine all nuclear power plants in the country.

Friday, July 08, 2011 03:25 +0900 (JST)

TEPCO to send workers into No.3 reactor building

The operator of the Fukushima Daiichi nuclear plant will send personnel, instead of a robot, into one of the reactor buildings to take steps to prevent a hydrogen explosion. But the work is likely to face difficulty because of the high radiation levels.

Tokyo Electric Power Company plans to inject nitrogen into the No.3 reactor to prevent another hydrogen explosion.

The utility used a camera-mounted robot on Wednesday to examine the No.3 reactor building to determine if it can connect injection pipes to the containment vessel. But TEPCO was unable to assess the situation because the robot couldn't reach the area.

TEPCO says it will send workers inside the reactor building instead. A few more days will be needed for the government to confirm safety before nitrogen can be injected.

The company hopes to complete the injection by July 17th according to its schedule, but the prospects remain unclear. Removing the risk of hydrogen explosions and stably cooling down the reactors are the keys to bringing the situation under control.

Friday, July 08, 2011 13:06 +0900 (JST)

Systematic involvement suspected in Genkai scandal

Kyushu Electric Power Company says its nuclear energy division may have been involved in a **systematic effort to manipulate public opinion** to support the restarting of its Genkai nuclear power plant.

Last month, the government held a meeting to explain safety measures to local residents before restarting the No.2 and 3 reactors at the plant in Saga Prefecture.

The meeting was broadcast live on TV and the internet, and viewers were invited to submit their opinions by e-mail or fax.

It was learned on Friday that the 2 of the utility's executives, including a vice president in charge of the nuclear energy division, instructed their subordinates to help with the effort, referring to the meeting.

The company previously admitted that employees of the utility and 4 affiliated firms -- more than 1,500 people in total -- were instructed to send e-mails during the meeting in support of the reactors' restart.

The 2 reportedly felt that the meeting was important because it took place just prior to Kyushu Electric's general shareholders' meeting.

They were also reportedly interested in the opinions sent to the meeting.

Industry Minister Banri Kaieda said he was deeply disappointed at the utility's behavior in light of the crisis at the Fukushima Daiichi nuclear power plant. He said he would like to prevent a recurrence of the scheme by keeping power utilities in check.

Friday, July 08, 2011 14:48 +0900 (JST)

TEPCO to inject nitrogen into No. 3 reactor

The operator of the crippled Fukushima Daiichi nuclear power plant is preparing to connect pipes to the plant's No. 3 reactor to inject nitrogen to prevent a hydrogen explosion.

Tokyo Electric Power Company **workers spent 10 minutes in the reactor building on Friday** to determine whether pipes can be connected to the reactor's containment vessel.

The utility says the workers confirmed that the reactor's connections are intact, and that work to lay the pipes can start on Saturday.

The firm had sent a robot equipped with a camera into the building to check the situation, but the device was blocked and could not finish the work.

Stably cooling the plant's reactors and preventing hydrogen explosions are the pillars of the utility's plan to bring the facility under control.

Nuclear crisis minister Goshi Hosono says that around July 17th, he hopes to begin studying whether to lift advisory designating areas where residents are required to be prepared to evacuate in case of emergency.

But the work to lay the pipes has already been delayed, and the Nuclear and Industrial Safety Agency must confirm safety for several days before beginning the nitrogen injection.

It remains uncertain whether the injection can be carried out by July 17th as scheduled.

Friday, July 08, 2011 19:48 +0900 (JST)

Residents in radiation hotspots anxious about evacuating as deadline for decision looms

Teachers see children onto a bus after the end of lessons at Oguni Elementary School in Date, Fukushima Prefecture, on June 30. The school has instructed children to wear masks, hats and long sleeves to protect them from radioactive materials. (Mainichi)

FUKUSHIMA -- Residents in areas where radiation hotspots have been detected are voicing worries that their communities will be split up, as the deadline for residents to decide whether or not to evacuate approaches.

Over one week has passed since 113 households in four areas of the Fukushima Prefecture city of Date have been placed under special evacuation recommendations. Residents in these hotspots must decide

for themselves whether or not to evacuate by July 8, but the level of support they will receive if they leave remains unclear.

Among the households to receive evacuation recommendations are 32 in the Kamioguni area of Date's Ryozenmachi district, and 54 in the Shimooguni area. Oguni Elementary School, which students in these two areas attend, has a total roll of just 57 children, of which 20 are in households subject to evacuation recommendations.

At a local information session on the recommendation designation, residents voiced concerns about the remaining students.

"Will the children who are left behind have to go to school along routes where there are high amounts of radiation?" one resident asked.

The school's 53-year-old principal said the district would have to work out measures such as using buses and taxis to get children to school. Residents in both regions have decided to submit requests to the central and Date municipal governments to have the whole regions placed under evacuation recommendations, rather than restricting recommendations to specific households.

In the Aiyoshi area of Date's Tsukidate district, the home of 83-year-old farmer Satsu Takahashi was placed under a special evacuation recommendation. The area is just two kilometers away from the edge of the village of Iitate, which was designated a "planned evacuation zone" and is now almost completely empty.

Workers measure the ground near a rain water outlet in Minamisoma, Fukushima Prefecture, on June 12. (Mainichi)

"I was feeling sorry for the people in Iitate, but I never thought that this would happen to me," Takahashi said. Thinking there would be no evacuation orders, Takahashi only recently planted a crop of kidney beans.

By selling the crop, Takahashi would get about 300,000 yen, but evacuating would leave the 83-year-old empty-handed. Residents of Iitate can receive provisional compensation payments from Tokyo Electric Power Co. (TEPCO), the operator of the Fukushima No. 1 Nuclear Power Plant behind the crisis, but it remains unclear whether residents in Date will get anything if they evacuate.

"I'm worried about whether or not to evacuate," Takahashi said. "We're one rank below Iitate and I wonder how compensation will work out."

Besides the rent for the places that residents who evacuate will move into, financial support measures for residents have been left all but blank. The government's dispute reconciliation committee for nuclear damage compensation will establish interim guidelines for compensation over the nuclear crisis at the end of this month, but measures for households under special evacuation recommendations in radiation hotspots have been left unaddressed.

The government's headquarters on local nuclear disaster countermeasures has already indicated that residents whose households are under special evacuation recommendations will not receive the same level of support as those in evacuation zones.

At a meeting to explain the situation to residents, the Date Municipal Government said that evacuees would be provided free rent wherever they moved to, but the issue of damages for the nuclear disaster had not been settled.

"We have absolutely no idea how many households will apply to evacuate," a city official said. "The designations came as a snap decision. Unless the situation is quickly reviewed, it will cause a lot of confusion locally."

(Mainichi Japan) July 8, 2011

Man freed after arrest for collecting radiation-contaminated rubble in Fukushima

A man has been freed after being held on suspicion of collecting rubble allegedly contaminated with radiation from the crippled Fukushima No. 1 Nuclear Power Plant without permission, the Mainichi has learned.

The man was arrested on March 26 after allegedly collecting about 1.8 metric tons of broken brick walls and other rubble from a house in Koriyama for a 42,000 yen fee without a license in violation of the Waste Disposal and Public Cleansing Law.

The Koriyama branch of the Fukushima District Public Prosecutors Office, however, decided to set him free without charge after **concluding that the law does not apply to waste contaminated with radioactive materials, and the rubble gathered by the man may be contaminated with radiation.** The prosecutors office declined comment on the case.

Police and other authorities concerned are asking the central government to quickly write a law to regulate contaminated waste to prevent the spread of radioactive materials through dumping.

The Environment Ministry's Office of Waste Recycling Program Planning said, "**The current exclusionary regulations do not define the density and dose of radioactive materials and may abet crime**, so we are looking into the possibility of revising the law."

(Mainichi Japan) July 8, 2011

Hopes for water purification, cooling system to bring Fukushima nuke plant under control

The No. 1 reactor building at the Fukushima No. 1 Nuclear Power Plant is seen from the air in this April 10 file photo provided by TEPCO.

One week has passed since a system to purify water contaminated with radioactive substances began operations at the tsunami-hit Fukushima No. 1 Nuclear Power Plant.

Stable operation of the system, which plays the role of cooling down the reactors and reducing the amount of radioactive water, is a prerequisite for bringing the crisis to an end.

However, **as the system was hastily installed over only a two-month period**, experts have expressed fears that it may develop trouble such as water leaks and that it may be vulnerable to aftershocks and typhoons.

"The total length of the piping in the system is four kilometers. No one can tell what kind of potential risks it has," said a Toshiba Corp. expert, who is responsible for operating part of the system.

In the water purification system, radioactive materials are removed from contaminated water after going through four devices -- an oil separation device produced by Toshiba, a cesium absorption unit made by U.S.-based Kurion Inc., a decontamination device manufactured by France-based Areva SA, and a Toshiba-made desalting machine.

The purified water is then injected into the reactors to cool them down.

By the end of June, approximately **120,000 cubic meters of radioactive water** had accumulated on the premises of the plant.

The plant's operator, Tokyo Electric Power Co. (TEPCO), managed to put the water purification system into operation on June 27 -- shortly before the water was feared to leak into the sea. Since July 2, the system has been able to treat enough water to cool down the reactors. **The system had treated over 16,800 cubic meters of radioactive water by July 8.**

Immediately after the tsunami generated by the March 11 Great East Japan Earthquake hit the plant, fresh water from outside sources, such as a nearby dam, had been used to cool down the reactors.

However, cooling water contaminated with radioactive substances began to leak outside the reactor buildings from containment vessels and other devices that sustained damage in the disaster. At the same time, if the amount of cooling water had been reduced, it would have caused the temperature and pressure inside the reactors to rise sharply. This problem had been regarded as a stumbling block to bringing the crisis to an end.

Since a roadmap to bring the plant under control, worked out by TEPCO, sets a goal of ensuring that the amount of radiation at the plant is on a steady decline by mid-July, TEPCO is now aiming to put the water recycling system into full operation.

The system can now treat slightly more than 1,000 cubic meters of contaminated water a day even though its target is 1,200 cubic meters. Furthermore, the system needs to be occasionally shut down to replace the radioactive cesium absorption filter. Therefore, the system's current operating rate is only 76 percent. If the rate remains as it is, TEPCO is expected to finish treating all radioactive water in early November. If the rate rises to 80 to 90 percent, the process will likely be completed in late October.

However, the prediction is based on the assumption that rain water and underground water will not infiltrate into the plant as a result of typhoons or other disasters and cause the level of contaminated water to rise.

"Bringing the crisis to an end largely depends on the weather," a TEPCO official says.

 [Click here for the original Japanese story](#)

(Mainichi Japan) July 9, 2011

TEPCO to start injecting nitrogen into No. 3 Fukushima reactor soon

This March 24, 2011 aerial photo taken by a small unmanned drone and released by AIR PHOTO SERVICE shows damaged Unit 3 of the crippled Fukushima Dai-ichi nuclear power plant in Okumamachi, Fukushima Prefecture, northeastern Japan. (AP Photo/AIR PHOTO SERVICE)

TOKYO (Kyodo) -- Tokyo Electric Power Co. said Saturday it will begin injecting nitrogen into one of the reactors at the Fukushima Daiichi power plant to prevent a hydrogen explosion, as soon as it gets the green light from the government's Nuclear and Industrial Safety Agency and local governments.

The latest move at the No. 3 reactor will be a strong indication that the utility, known as TEPCO, can achieve stable cooling of the crippled reactors by mid-July as initially planned as it has already begun injecting the substance at its Nos. 1 and 2 reactors.

The injection of nitrogen into the No. 3 reactor is part of what is known as "step one," which is likely to be achieved by July 17. The utility began injecting nitrogen in the No. 1 unit from April. But for the No. 3 unit, there was no prospect of doing so due to stalled preparation work in the building because of excessively high radiation there.

TEPCO said it can start injecting nitrogen as early as within several days after connecting the hoses to the pipes at the reactor. **It found out on Friday that the pipes and hoses are easy to connect and would take only a few days to connect them.**

TEPCO also said the government agency instructed the utility to submit a report concerning nitrogen injection and the utility decided to proceed with the preparation for the procedure at the No. 3 reactor.

In this photo taken on June 22, 2011 and released on Thursday, June 23, 2011 by Tokyo Electric Power Co. (TEPCO), workers in protective suits set up temporary pressure gauges in the Unit 2 reactor building at the tsunami-damaged Fukushima No. 1 nuclear plant in Okuma, Fukushima prefecture. (AP Photo/Tokyo Electric Power Co.)

Under the current road map, TEPCO plans to achieve a cold shutdown of the reactors during the three to six months after step one is cleared.

(Mainichi Japan) July 9, 2011

Govt., TEPCO draw roadmap to reactor decommission

A roadmap toward decommissioning of the damaged Fukushima Daiichi nuclear power plant indicates that the removal of melted nuclear fuel rods at the plant may begin in 10 years.

NHK has obtained the mid- and long-term roadmap which was presented when officials from the operator of the Fukushima plant, government officials in charge of nuclear safety, and manufacturers of nuclear reactors met last week.

The draft roadmap drawn up by the government's Nuclear Safety Commission and Tokyo Electric Power Company says they tentatively set a target date to begin removing fuel rods that melted and fell to the bottom of the reactor.

The work is considered to be the most important phase in the decommissioning process. The roadmap indicates that removal will start in 2021 if technology essential for the work has been developed before that.

The timeline is believed to have been set based on measures taken following the 1979 Three Mile Island accident in the United States.

But unlike the US case, as reactor containment vessels were damaged at the Fukushima complex, they need to be fixed and filled with water.

The roadmap shows that reactor buildings could be finally demolished and cleared away after the removal of melted fuel rods is completed, and that it will possibly take dozens of years.

Survey: radioactive materials found in plankton

A scientific survey has found radioactive substances in plankton collected from the seafloor off Fukushima Prefecture.

A group of researchers from the Tokyo University of Marine Science and Technology ended its 8-day survey on Friday. The goal was to study the spread of radioactive materials into the Pacific Ocean from the Fukushima Daiichi nuclear power plant. The group collected samples from the seabed along a 120-kilometer stretch off the coast of Fukushima.

Radioactive cesium was found in animal plankton collected 35 kilometers off Iwaki City. The level was measured at 6 becquerels per kilogram.

The researchers say this level does not exceed the national safety standard. They added that the level would still be under the limit even if the cesium were to enter the bodies of larger fish that eat the contaminated plankton.

Professor Takashi Ishimaru, a member of the research group, says he and his colleagues will continue the survey to check the effects of radioactivity on the local ecosystem.

Saturday, July 09, 2011 06:14 +0900 (JST)

Radiation detected in beef from Fukushima

Beef from Fukushima Prefecture has been found to contain levels of radiation that exceed Japan's safety standards.

The Tokyo Metropolitan Government announced on Friday that it had detected 2,300 becquerels per kilogram of radioactive cesium in beef from a cow raised in a Minami Souma. The national limit is 500 becquerels per kilogram.

The Tokyo Government says the beef was not made available to consumers.

Japan's Health Ministry says this is the first time that beef has been found with such high levels of radioactivity following the accident at the Fukushima Daiichi nuclear power plant. The ministry has requested 6 prefectures near Fukushima to step up checks on beef.

Saturday, July 09, 2011 06:14 +0900 (JST)

Four cities request bigger nuclear safety zone

Four municipalities around a nuclear power plant in Shizuoka Prefecture have asked the central government to expand the plant's official emergency zone, so their communities can be included in the event of a nuclear accident.

Mayors and representatives from the cities of Fujieda, Yaizu, Fukuroi and Iwata handed a petition requesting the change to nuclear crisis minister Goshi Hosono on Friday.

The mayors asked that the emergency planning zone around the Hamaoka nuclear power station be expanded from the current 10-kilometer radius to 30 kilometers.

The municipalities are all located 10 to 30 kilometers from the Hamaoka plant.

The petition notes that in the Fukushima accident, evacuation areas have now expanded beyond the zone initially mandated by the government.

The mayors said the municipalities are unable to draw up evacuation plans unless their locations are recognized within the emergency zone. They said the matter is raising concern among residents.

Hosono agreed the Fukushima accident revealed the inadequacy of a 10-kilometer radius, and said the government must promptly review the matter.

La décontamination de Fukushima prendra des décennies selon le gouvernement

LEMONDE.FR avec AFP | 09.07.11 | 18h57 • Mis à jour le 09.07.11 | 19h16

Une photo aérienne de la centrale de Fukushima montre les dégâts provoqués par le tsunami du 11 mars.AP

Le premier ministre japonais a déclaré samedi 9 juillet que la décontamination du site de la centrale nucléaire de Fukushima prendrait plusieurs dizaines d'années. [Naoto Kan](#) présentait pour la première fois un programme de très long terme pour cette opération.

Les systèmes de refroidissement de la centrale nucléaire de [Fukushima Daiichi](#), située à 220 km au nord-est de Tokyo, ont été endommagés entraînant une fusion au sein de trois réacteurs après le tsunami ayant suivi le séisme du 11 mars, provoquant l'une des pires catastrophes du nucléaire civil. *"Un grand nombre d'habitants ont été contraints d'évacuer" la zone, a déploré M. Kan au cours d'un meeting du [Parti Démocratique](#) au pouvoir au Japon. "Il faudra trois, cinq, voire 10 ans pour parvenir à en reprendre le contrôle, et même plusieurs décennies pour remédier aux conséquences de l'accident", a-t-il ajouté.*

La Commission japonaise à l'énergie atomique et l'exploitant de la centrale de Fukushima, [Tokyo Electric Power](#) (Tepco), sont convenus dans un premier temps de commencer à retirer le combustible nucléaire fondu vers 2021, selon la chaîne de télévision publique NHK. La chaîne de télévision a rapporté que les autorités, l'opérateur et les fabricants d'équipements estimaient qu'il faudrait *"plusieurs décennies"* avant de pouvoir démanteler les réacteurs de la centrale, citant un programme de long terme pour reprendre le contrôle de la centrale.

Le Japon a annoncé un programme de court terme pour stabiliser la centrale nucléaire de Fukushima Daiichi, responsable d'émissions radioactives de très haut niveau après la panne de ses systèmes de refroidissement. Mais avant samedi, le gouvernement n'avait encore présenté aucune estimation de la durée du programme de décontamination nécessaire pour mettre fin à la crise.

Le projet, que s'est procuré NHK, s'inspire d'une étude des données sur la manière dont les [Etats Unis](#) ont procédé lors de l'accident nucléaire de la centrale de [Three Mile](#) en 1979, a précisé la chaîne. Tepco espère réduire les fuites radioactives d'ici à fin juillet et parvenir à refroidir les réacteurs pour les arrêter au plus tard d'ici à janvier prochain. Goshi Hosono, le ministre chargé de gérer les conséquences de l'accident nucléaire, a déclaré à [Jiji Press](#) que le gouvernement annoncerait le 19 juillet un nouveau programme de décontamination du site et sa vision à long terme de la gestion de l'accident

A Fukushima, des taux de radioactivité quatre fois supérieurs à la limite légale

LEMONDE.FR avec AFP | 05.07.11 | 12h22 • Mis à jour le 09.07.11 | 19h15

Une photo aérienne de la centrale de Fukushima montre les dégâts provoqués par le tsunami du 11 mars.AP

Des niveaux de radioactivité jusqu'à quatre fois supérieurs à la limite légale ont été mesurés dans les sols de la ville de Fukushima, à 60 kilomètres de la centrale nucléaire accidentée, selon des associations de résidents. Elles réclament désormais l'évacuation des enfants et des femmes enceintes de la ville, pour éviter les risques sanitaires.

Une des mesures effectuée dans cette cité de près de 300 000 habitants a fait état d'un taux de césium radioactif de 46 540 becquerels par kilogramme, alors que le taux maximum légal est de 10 000 becquerels au Japon. Un niveau qui dépasse le seuil à partir duquel les autorités soviétiques ont procédé à l'évacuation des populations après la catastrophe nucléaire de Tchernobyl en 1986, selon les associations à l'origine des analyses.

"LA CONTAMINATION DES SOLS S'ÉTEND"

Les trois autres prélèvements effectués dans le sol de la ville de Fukushima ont fait apparaître, après analyse, des taux compris entre 16 290 et 19 220 becquerels par kilogramme.

"La contamination des sols s'étend dans la ville", a prévenu l'auteur des analyses, Tomoya Yamauchi, professeur à l'université de Kobé spécialiste des radiations. "Les enfants jouent avec la terre, ils jouent donc avec des substances hautement radioactives", a-t-il ajouté, soulignant qu'il fallait procéder à des évacuations "au plus vite."

Quelque 160 000 personnes riveraines de la centrale ont évacué leur maison depuis l'accident nucléaire. Environ la moitié a regagné son domicile depuis mais les autres, qui vivaient dans un rayon de 20 km du site pour la plupart, ne sont pas retournées chez elles.

Provoqué par le séisme de magnitude 9 et le tsunami géant qui ont dévasté le nord-est du Japon le 11 mars, l'accident de la centrale Fukushima Daiichi (Fukushima n° 1) a entraîné d'importants rejets radioactifs dans l'atmosphère, l'eau de mer et les sols de cette préfecture.

Scientists launch 'operation sunflowers' to decontaminate farmland near nuclear plant

Professor Masamichi Yamashita measures radiation levels around sprouting sunflower seeds in Katsurao, Fukushima Prefecture, on July 2, 2011. (Mainichi)

NAMIE, Fukushima -- Scientists have launched "operation sunflowers" in a bid to remove radioactive cesium from the ground in an evacuation zone near the Fukushima No. 1 Nuclear Power Plant so that local residents could return and farm the land again.

A group of scientists, led by space agriculture professor Masamichi Yamashita at the Japan Aerospace Exploration Agency (JAXA), had planted sunflower seeds on farmland in three locations in Namie and Katsurao, Fukushima Prefecture, on an experimental basis after receiving approval from the owners of the farmland. The group visited the farmland again on July 2 and confirmed the seeds were sprouting. The levels of radiation one meter above the ground in the area were rather high, ranging from 7 to 21 microsieverts per hour.

According to Yamashita, radioactive cesium is similar to kalium used as an agricultural fertilizer. When sunflowers grow tall and large, they could absorb large quantities of cesium, and therefore they were used to decontaminate toxic soil in the wake of the 1986 Chernobyl nuclear accident.

If the sunflowers that have absorbed cesium are burned, the radioactive cesium could be dispersed into the atmosphere. Therefore, Yamashita and other researchers are planning to use bacteria to decompose the sunflowers and reduce the volume of the plants and treat them as radioactive waste.

"If we can verify that sunflowers absorb cesium efficiently, we want to expand the area for growing sunflowers," said Yamashita. Michio Konno, 55, who offered his rice field for the project, said, "Farmers left Namie with an unbearable feeling. We want to have the soil back to normal so that everyone can come back to Namie."

TEPCO suspends decontamination system

The operator of the Fukushima Daiichi nuclear power plant has suspended part of the activity of the radioactive water decontamination system as **a liquid substance was found leaking from the device.**

Tokyo Electric Power Company, or TEPCO, said that it stopped the system on Sunday morning. The liquid was found leaking from the hose for injecting chemicals to break down radioactive materials in the French-made device.

About **50 liters** of liquid is believed to have leaked.

TEPCO said it is **examining whether the liquid was the chemicals or radioactive water**, as well as the cause of the leak. The company added that it is doing its best to resume the operation as soon as possible.

The system to recycle decontaminated water is the key to cooling reactors.

But TEPCO has to shut down the system frequently as it has been having continued problems since the start of its use on June 27th.

The utility has only one week left until July 17th, when it is scheduled to complete the first stage of the plan to bring the facility under control.

But the operating rate of the system during the week through last Tuesday was below the target, showing the difficulty the firm is facing.

Sunday, July 10, 2011 16:46 +0900 (JST)

TEPCO temporarily halts water decontamination system after leak

TOKYO (Kyodo) -- Tokyo Electric Power Co. said Sunday it temporarily halted the system to decontaminate radioactive water at the crippled Fukushima Daiichi nuclear power plant in Fukushima Prefecture after discovering that about 50 liters of contaminated water and chemicals used in the system were leaking from a pipe after a part broke.

The utility known as TEPCO has been using the decontaminated water to cool the Nos. 1-3 reactors at the plant, and even during the temporary suspension to fix the part, it was able to continue the cooling function using water that had already been decontaminated, it said.

"The concentration of radioactive substances in the leaked contaminated water was not at levels that would cause problems involving workers' exposure to radiation," a TEPCO official said.

The leak occurred in a section of a device developed by France's Areva SA where the chemicals, which are used to condense and precipitate radioactive materials in the contaminated water, are injected from a hose into a pipe through which the polluted water passes, according to TEPCO.

The plastic part broke, causing the chemicals and contaminated water to leak, the company said, adding that workers replaced the part with a steel one and resumed operation of the water treatment system.

The chemicals are not toxic, TEPCO said.

Smooth operation of the treatment system, which is designed to remove highly radioactive materials from the massive quantities of contaminated water accumulating at the power station, is essential for containing the nuclear crisis, as TEPCO recycles the water to cool the plant's damaged reactors.

The contaminated water accumulating at reactor facilities, including coolant liquid leaking from damaged reactors, has been diverted elsewhere at the plant to prevent it from overflowing from the facilities, but the storage locations are nearing full capacity.

(Mainichi Japan) July 11, 2011

Experts warn that drug's benefits unproven for low-dose radiation dosages

Prussian blue, sold as a medical product in Japan and elsewhere. (Mainichi)

The government is warning people to only take radiation medicine as prescribed by doctors, saying that the pigment Prussian blue, meant to be taken after heavy doses of radioactive cesium, is not known to have an effect on low-dose radiation and might even cause side effects such as irregular heartbeat.

The pigment Prussian blue, which is also used in paints, was found to encourage the ejection of cesium-137 when it was used on 46 people exposed to the isotope in an incident in Brazil in 1987. It was found to be particularly effective on adults. However, almost no other data on Prussian blue's

medical use exists. A German pharmaceutical company put the pigment into capsule form and began selling it in 1997 under the name Radiogardase.

Prussian blue is said to cut down the length of time that cesium-137 stays in the human body by two thirds, and the World Health Organization has recommended that all countries keep stocks on hand. It was approved for sale in Japan in October last year. Possible side effects are feared such as constipation and potassium deficiency in the blood, which can lead to irregular heartbeat.

At a June 30 press conference by the government and Tokyo Electric Power Co.'s disaster response team, Kazuhiko Maekawa, professor emeritus of emergency medicine at the University of Tokyo, said that "the effects (of Prussian blue) on low-dose radiation dosages are completely unknown."

After the crisis at the Fukushima No. 1 Nuclear Power Plant began, Tokyo-based pharmaceutical company Nihon Medi-Physics made an emergency import of 72,000 capsules from Germany and gave them for free to the Japanese government. However, none of the capsules have yet been reported used.

Regular medical institutions do not handle Prussian blue. According to Nihon Medi-Physics, very soon after the nuclear disaster began, multiple drug importers started offering sales of Prussian blue direct to consumers via the Internet.

The Ministry of Health, Labor and Welfare's disaster response headquarters has commented that its intended use of Prussian blue is for "workers engaged in repair work at the power plant who are subjected to acute radiation dosages." It added that, "side-effects are considered possible, and we do not recommend that people obtain or use Prussian blue on their own."

On the website of the National Institute of Radiological Sciences (NIRS), it is suggested that if a patient's internal radiation exposure is around 300 millisieverts then there is reason to give Prussian blue, but if the exposure is a tenth of that at 30 millisieverts, then the drug should not be administered.

The NIRS has asked medical facilities to give radiation medicine based on doctors' prescriptions, use whole-body counters -- which can measure internal radiation doses -- to measure the effects of the treatment, and report data on treatment to the NIRS.

Dismantling Fukushima Daiichi nuclear plant to take several decades

TOKYO (Kyodo) -- The full dismantling of the crisis-hit Fukushima Daiichi nuclear power plant, including removing nuclear fuel and tearing down reactors and the buildings housing them, is expected to take several decades, sources familiar with the matter said Saturday.

Under a medium- to long-term plan being discussed by the government, the plant's operator and reactor manufacturers, **the removal of spent fuel rods in cooling pools would start three years after the nuclear**

crisis comes under control and the removal of fuel from reactors would start in fiscal 2021, the sources said.

Despite the tentative targets for removing fuel rods, the specific tasks involved has not been worked out as fuel in the Nos. 1, 2 and 3 reactors has melted through the pressure vessels and the containment vessels of the Nos. 1 and 2 reactors are likely damaged, they said.

The plan has been discussed separately from the already established timetable for bringing the critical situation at the six-reactor plant under control by around January.

The Japan Atomic Energy Commission in the Cabinet Office is leading the discussions among organizations involved, such as the government's Nuclear and Industrial Safety Agency and Tokyo Electric Power Co., which runs the Fukushima complex damaged by the March 11 earthquake and tsunami.

In this image released Saturday, April 16, 2011, by Tokyo Electric Power Co., top of the container of the nuclear reactor, painted in yellow, of Unit 4 at the Fukushima Dai-ichi Nuclear Plant is observed from its side with a T-Hawk drone Friday, April 15, 2011 in Okuma, Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

Experts say the dismantling process could take longer as the containment vessels of some of the reactors have been damaged and there are still instances of leaks involving water injected into the reactors to keep nuclear fuel cool.

(Mainichi Japan) July 11, 2011

Makeshift equipment at Fukushima hit by problems

The operator of the Fukushima Daiichi nuclear power plant has been struggling for months to bring the plant's troubled reactors under control using **makeshift equipment**.

Since the March 11th disaster, Tokyo Electric Power Company has installed a number of **improvised devices and systems** to cool down the reactors and decontaminate radioactive water building up at the plant.

But these makeshift facilities have been plagued by glitches.

Earlier this month, the No. 5 reactor's cooling system was temporarily shut down after sea water leaked from a crack in the system's makeshift hose.

TEPCO says the hose was installed in a wrong way. It is reinstalling it on Monday.

The company says it is necessary to make the plant's makeshift equipment more durable, as it is expected to take some time to bring the reactors under control.

It says the makeshift hosing, in particular, requires more elaborate measures, as it carries highly contaminated water.

Monday, July 11, 2011 13:13 +0900 (JST)

Cesium found in hay fed to beef cattle

Radioactive cesium far exceeding the legal limit has been detected in hay at a cattle farm in Fukushima Prefecture. The prefecture has been investigating how the cattle became contaminated with the radioactive substance.

Officials took samples of feed and well water at the farm in Minamisoma City on Sunday.

They say cesium far exceeding the government's safety limit of 300 becquerels per kilogram has been detected in the feed.

The farmer says the cows had been kept inside but were fed with hay left outdoors after the March nuclear accident.

Eleven cows from the farm were sent to Tokyo to be slaughtered. The beef from the animals contained levels of cesium that were more than triple the legal limit. The prefecture has asked farmers in the city to suspend beef cattle shipments.

Fukushima Prefecture will continue to investigate the feed and water and check if there were any problems with the way the cattle were raised.

Monday, July 11, 2011 12:50 +0900 (JST)

Long-term response needed for radioactive water

The operator of the Fukushima Daiichi nuclear power plant is struggling to deal with radioactive water that is pooling in reactor buildings as the crisis goes into its 5th month.

Water being injected to cool reactors is becoming highly radioactive and accumulating in the basements of reactor buildings. In some facilities, contaminated water is just 20 centimeters from filling the basement.

On July 2nd, Tokyo Electric Power Company stopped using fresh water to cool the reactors and instead, began running a circulatory cooling system. The system pumps out and decontaminates

radioactive water before recycling it as a coolant.

But the system has suffered from a series of problems. **On Sunday it was suspended for 12 hours as radioactive water leaked from a decontamination device.**

Many of the glitches were caused by **non-durable materials used in parts of the system.**

The power firm is replacing some of the troublesome materials with more durable ones. Preparing a long-term response to deal with contaminated water will require making the entire decontamination device sturdier.

Monday, July 11, 2011 05:42 +0900 (JST)

Minami-soma starts internal radiation checks

Minami-soma City in Fukushima Prefecture has begun checking the internal radiation levels of its residents.

Two locations in the city have measured radiation of 20 millisieverts or higher per year, a level that prompts the authorities to recommend the evacuation of nearby residents.

State and prefectural authorities are continuing their monitoring with the aim of designating the areas as radioactive hotspots, despite being outside the government-designated evacuation zone around the Fukushima Daiichi nuclear plant.

The residents who were examined at the city-run general hospital on Monday are living near these 2 areas.

After completing a questionnaire, the residents were checked for radiation with a whole body counter.

A 20-year-old man says he's very concerned about the outcome of the tests.

Minami-soma City says it will give priority to checking the radiation levels of residents and children, and **7,000 residents will undergo the checks by the end of next March.**

Monday, July 11, 2011 15:10 +0900 (JST)

TEPCO suspends water decontamination system

http://www3.nhk.or.jp/daily/english/18_10.html

Tokyo Electric Power Company has halted operation of a system to decontaminate highly radioactive water at the Fukushima Daiichi nuclear plant as **one of the parts reached its radiation exposure limit in less than 5 hours.**

The system went into service on Friday night.

One component of the system uses the mineral zeolite to absorb radioactive cesium. A replacement part of the US-made device had been expected to last one month, but radiation exceeding the maximum 4 millisieverts per hour led to the dramatically shortened lifespan.

TEPCO suspended operation of the device early on Saturday to determine the cause.

The utility says it has so far found no abnormalities with the system or water leakage in the system. It adds that the device's dosimeter may have detected radiation from nearby pipes containing contaminated water or other radioactive materials.

The treatment system holds the key to halting the accumulation of highly radioactive water and re-circulating contaminated water to cool the reactors.

Saturday, June 18, 2011 13:00 +0900 (JST)

Spent fuel causing headaches for nuclear power plants

2011/06/29 <http://www.asahi.com/english/TKY201106280424.html>

The accident at the Fukushima No. 1 nuclear power plant has brought to light the cascading problem of spent nuclear fuel that threatens to overwhelm Japan's nuclear power plants.

Local governments are demanding that electric power companies remove the spent nuclear fuel from nuclear power plants, but plans for a reprocessing facility and an off-site storage facility are on hold.

According to a survey by The Asahi Shimbun, **while the nation's 17 nuclear power plants are capable of holding 83,000 spent nuclear fuel assemblies in storage pools, 70 percent of the combined storage capacity has already been used.**

Tokyo Electric Power Co.'s Fukushima No. 1 nuclear power plant has the highest ratio of 93 percent, followed by Japan Atomic Power Co.'s Tokai No. 2 nuclear power plant in Ibaraki Prefecture with 86 percent.

The figure exceeds 60 percent at 10 other nuclear power plants.

If storage pools are filled, a nuclear power reactor cannot continue to operate because newly created spent nuclear fuel cannot be removed from the reactor.

At the Fukushima No. 1 and Tokai No. 2 nuclear power plants, operators have put some spent nuclear fuel in containers and stored them in a separate building on the plant premises.

Spent nuclear fuel needs to be cooled in storage pools because it emits large amounts of heat and radiation even after it is removed from a reactor.

But fuel in storage pools, mainly located in reactor buildings, is separated from the outside only by the buildings' concrete walls, while a pressure vessel within a container vessel holds nuclear fuel in a reactor.

In the accident at the Fukushima No. 1 nuclear power plant, storage pools lost cooling functions, raising the possibility that spent nuclear fuel is damaged and large amounts of nuclear materials are released.

Electric power companies are resorting to a last-ditch measure known as "**re-racking.**"

In storage pools, spent nuclear fuel is usually put into grid-like containers called racks and placed at certain intervals.

Re-racking means that racks are repositioned and intervals are narrowed so that more spent nuclear fuel is stored in a given space.

A survey by The Asahi Shimbun found that electric power companies have taken this approach at 29 nuclear power reactors.

TEPCO repositioned spent nuclear fuel at the Fukushima No. 1 and No. 2 nuclear power plants in the past.

At the Hamaoka nuclear power plant in Shizuoka Prefecture, Chubu Electric Power Co. more than doubled the capacity of the No. 2 reactor's storage pool to 1,820 spent nuclear fuel assemblies from the initial 840.

Currently, the pool contains 1,164 assemblies. The No. 2 reactor, which started operations in 1978, has been shut down for decommissioning.

But experts say narrowing intervals between spent nuclear fuel could increase risks.

Tadahiro Katsuta, associate professor of nuclear engineering at Meiji University, said re-racking is a stopgap measure.

"Nuclear fuel assemblies will be located closer to each other than initially designed," Katsuta said. "At least theoretically, the possibility will increase that criticality (self-sustaining nuclear chain reaction) occurs when assemblies are damaged in a severe accident."

To lower such risk, boron is added to rack materials because the chemical element absorbs neutrons, which cause nuclear fission.

Electric power companies are also considering **plans to build intermediate facilities to store spent nuclear fuel in steel containers that can shield radiation.**

An official of Kansai Electric Power Co., which operates 11 nuclear power reactors in Fukui Prefecture, said, "We are aware of the need of building an intermediate storage facility and are considering it."

Japan aims to recover plutonium from spent nuclear fuel at a reprocessing facility for use as nuclear fuel again.

The spent nuclear fuel reprocessing facility is scheduled to begin operations in Rokkasho, Aomori Prefecture, in October 2012.

But the plant was suspended during trial runs due to a series of technical problems, and no date has been set for resuming trial operations.

The reprocessing plant has accepted spent nuclear fuel from nuclear power plants, but there is little room left because the amount has exceeded 90 percent of its capacity.

TEPCO and Japan Atomic Power are planning to build an intermediate storage facility in Mutsu, Aomori Prefecture, to accept 5,000 tons of spent nuclear fuel that cannot be held at their nuclear power plants for 50 years.

But construction was suspended after the Great East Japan Earthquake.

"I think the government is considering reviewing safety guidelines," Mutsu Mayor Junichiro Miyashita told a news conference in April. "With such a move in mind, we have to take a cautious stance to the intermediate storage facility."

Longtime anti-nuclear engineer prepared to fight from within field to right wrongs

It was dim in the narrow office at Kyoto University's Research Reactor Institute, where Hiroaki Koide, an assistant professor, sat at his desk one afternoon. The florescent lights were kept off, and despite the heat, so was the air conditioning.

"I don't use any unnecessary energy," said Koide, who has long been an anti-nuclear power activist. "Everyone has come to lead excessively luxurious lives, using things they don't need."

Stacks of documents and other literature on nuclear power were packed inside the small space, and once I took a seat, there was no room left for either of us to move.

An expert in radiation metrology and nuclear safety, Koide for years has rallied behind victims of radioactive materials. He served as a witness for the plaintiffs in a lawsuit seeking to revoke the construction permit given for the Ikata Nuclear Power Plant in Ehime Prefecture, and when the Tokaimura nuclear accident took place in 1999, he took on the task of measuring soil radiation levels. In another case, he was involved in estimating the number of cancer deaths in a certain area.

Ever since the disaster at the Fukushima No. 1 Nuclear Power Plant emerged, Koide has voiced criticism of the government and plant operator Tokyo Electric Power Co (TEPCO) over their handling of the crisis in various forums including newspapers, television, radio and lectures. His book, "Genpatsu no Uso" (Lies about nuclear power plants) released in June, has sold 200,000 copies. He has never been busier.

Born in Tokyo's Taito Ward, Koide graduated from Kaisei Senior High School and went on to study nuclear engineering at Tohoku University's School of Engineering, where he says he never missed a class.

"At the time, I believed that nuclear power was the energy of the future. I had it in my head that I wanted to use the incredible energy of atomic bombs for peaceful purposes," he said.

In 1969, the same year that he witnessed the violent clash between student activists and riot police at Tokyo University's Yasuda Hall on television, Koide learned about the controversy surrounding the planned construction of Onagawa Nuclear Power Plant straddling the Miyagi Prefecture town of Onagawa and city of Ishinomaki. Local fishermen were protesting the plant, questioning why a power plant that would supply most of its energy to the prefectural capital of Sendai had to be built in their backyard.

Koide was forced to rethink the issue of nuclear power plants, and reached a conclusion: If there were ever an accident at Onagawa Nuclear Power Plant, local residents would suffer health problems if they continued to live in the vicinity. At the same time, preventing residents from suffering such problems would mean they could no longer live in their hometowns.

It was 42 years later -- albeit in Fukushima Prefecture -- that Koide's concerns became reality.

Nuclear engineering departments at universities exist for the purpose of churning out scientists and technical experts who will go on to take a role in nuclear power generation. While some of his colleagues left the field for moral reasons, Koide decided he would stay and continue blowing the whistle on its problems.

Learning by chance that the **Kyoto University Research Reactor Institute** had an assistant professorship open, Koide applied and was accepted in the spring of 1974. By the time he joined the institute, there already were four assistants on staff who objected to nuclear energy. Koide went on to support lawsuits that involved nuclear power plants, and he, along with the four other anti-nuclear engineers and Tetsuji Imanaka, who joined the staff later, were dubbed the "**Anti-nuclear Gang of Six**" -- a twisted reference to the "Gang of Four" (a group of four Chinese Communist Party officials who were notorious for promoting the policies of the Cultural Revolution). The six scientists were at times even accused of being anti-national.

The Kyoto University Research Reactor Institute was established in 1963 for joint use by universities around the country, enabling them to conduct research utilizing its nuclear reactors. So why were Koide and the others who expressed opposition to the use of nuclear energy able to stay on the staff?

"The reactors here were built as a tool for producing neutrons. Whether one is pro- or anti-nuclear power is irrelevant, because the use of neutrons is applicable to the fields of physics, chemistry, and

medicine for cancer treatment," Koide said. "That said, the culture at Kyoto University of respecting the free will of its staff probably had something to do with it."

Koide avoids directly answering the question of why he has remained an assistant -- not a full -- professor for so many years by saying: "I'm an outsider (even considering the university where I received my degree)." Yet, he doesn't hold back on his criticism of Japan's "nuclear power village," a term referring to the cozy ties among the nuclear industry, academics, media and government.

"There's a vigorous screening process (for membership to "the village"). For example, if you're at the University of Tokyo and don't support state policies, you're out. The success of your career depends on the extent of your cooperation with the government," Koide said.

Called upon to testify before the House of Councillors Government Oversight Committee on May 23, Koide brought up the Seven Social Sins taught by Mohandas Gandhi. Of those, Koide said that "commerce without morality" described TEPCO and "science without humanity" applied to the nation's academic traditionalism, of which he himself declared to be guilty.

"The lives that people have led have been pulled out by the roots," Koide said quietly. "Considering the land, lives, and health that are going to be lost, it's impossible for me to say that nuclear power will somehow work out through scientific progress."

Koide has a large photo of Shozo Tanaka posted on a partition that divides his part of the office from his officemate's. He says that he holds the Meiji-era politician, who spent his life trying to help the victims of Ashio Copper Mine pollution incident, in the highest esteem.

When the industrial pollution incident took place, Japan was about to rush headlong into the Russo-Japanese War as it sought to become one of the great powers of the world. It was under such circumstances that Tanaka blew the whistle on the mineral poisoning of the Watarase River basin in Gunma and Tochigi prefectures. The story of Tanaka's direct appeal to the Meiji emperor and his efforts to save the local farmers in exchange for his own life is all too famous in Japan.

Coincidentally, on March 8, just days before the Great East Japan Earthquake and tsunami triggered the nuclear disaster in Fukushima, a handwritten tanka poem penned by Tanaka during his later years was found in Tochigi Prefecture. In it, Tanaka says that there is no point in begrudging criticism, and that joy is bound to come from sacrificing one's life and throwing oneself into something wholeheartedly.

"Up until his death, Shozo was there for the farmers who had been abandoned by the state," Koide explained. "Even when he was dying, he was more concerned about the mineral poisoning than he was about his own illness, and continued to encourage the local residents. It was a very gracious way to live one's life."

In this photo from a footage of a live camera released by Tokyo Electric Power Co. (TEPCO), black smoke billows from the crippled Fukushima No. 1 Nuclear Power Plant in Okumamachi, northeastern Japan, on March 22, 2011. (AP Photo)

Today, the nuclear crisis mirrors the industrial pollution case to which Tanaka dedicated himself.

Koide says that nuclear power plants force burdens on people on various levels.

"Nuclear power plants are fraught with risks that urban areas are unable to take on. Urban residents are forcing those risks onto people living in sparsely-populated areas, who are in a more vulnerable position in society. Even if we were able to prevent nuclear accidents, the volume of radioactive waste on our hands will continue to increase, and mankind does not have a way to render such waste harmless," he said. "Our generation is forcing that 'poison' onto future generations who have no say in the matter."

This "responsibility to future generations" is something on which Koide has long placed great importance.

"As someone in the field of nuclear power, I have a different responsibility from that of the layperson. But I believe that the general population also has a responsibility. Maybe you were conned by nuclear power proponents. But you must claim responsibility for having been duped."

Koide, a self-proclaimed maverick, seems prepared to face the long, grim battle that awaits Japan, where there currently are 54 nuclear reactors -- the third highest number in the world after the U.S. and France.

"The adults are the ones who have been promoting nuclear power, but it is our children who will likely bear the burden that comes with it. I want to fulfill my own responsibilities in order to somehow reduce their suffering," Koide says. (By Mamoru Shishido, Mainichi Shimbun)

Réchauffement des relations entre EDF et Areva

Luc Oursel, le successeur d'Anne Lauvergeon à la tête d'Areva, et Henri Proglio, le patron d'EDF, sont attendus le 25 juillet en Bourgogne aux côtés du ministre de l'Energie, Eric Besson. Les salariés de l'équipementier espèrent une grosse commande.

Tout un symbole. Un mois après le départ de la patronne d'Areva, Anne Lauvergeon, son successeur Luc Oursel devrait se trouver, le 25 juillet en Bourgogne, au côté d'Henri Proglio, le patron d'EDF, à l'occasion de l'installation du comité stratégique de filière nucléaire par le ministre de l'Energie Eric Besson. A croire que le changement de casting permettra enfin une relation apaisée entre les deux fleurons de l'atome tricolore. *« Il y aura un certain nombre d'inflexions, et l'une des inflexions les plus importantes, c'est que nous voulons un dialogue serein, et de grande qualité, entre EDF et Areva »*, a répété vendredi Eric Besson sur Europe 1.

En Saône-et-Loire, où se trouvent plusieurs usines d'Areva, on veut voir dans cette visite le signe d'un gros contrat imminent. *« Ils veulent annoncer une commande conséquente pour Areva de remplacement par EDF de générateurs de vapeur dans les centrales nucléaires françaises, croit savoir Patrick Buchot, délégué syndical central CFDT chez Areva NP, la filiale de réacteurs. On pourrait se voir attribuer un marché compris entre 28 et 36 générateurs de vapeur sur 44, ce qui permettrait de relancer pleinement la production du secteur équipement d'Areva en Saône-et-Loire. »*

La perspective d'une commande importante semble se confirmer, mais EDF reste très prudent sur la question. *« Les discussions sont en cours. Cela peut aller très vite comme cela peut traîner »*, indique sobrement une source proche du dossier. Elle assure que la décision ne sera connue qu'en septembre, après l'accord du conseil d'administration. Une précaution d'usage dans le cadre d'un appel d'offres européen de cette ampleur -entre 1 à 2 milliards d'euros -comme c'est le cas pour ces gros composants.

Historiquement, Areva était le fournisseur exclusif d'EDF pour ce genre de produits. Mais le groupe a dû accepter la concurrence du japonais Mitsubishi Heavy Industries lors d'appels d'offres récents. Cette fois-ci, il se trouve en compétition avec le même japonais ainsi que l'américain Westinghouse. EDF veut faire jouer la concurrence, mais aussi diversifier ses risques. *« On veut être sûrs d'être livrés dans les délais »*, indique un responsable, citant un retard d'un an d'Areva pour la livraison d'un générateur de vapeur pour la centrale de Bugey.

Sur le fond, l'Etat, actionnaire d'EDF et Areva, ne peut pas se permettre de délaisser l'équipementier nucléaire au moment où son avenir est assombri par la catastrophe de Fukushima. De son côté, Luc Oursel affiche son intention de travailler étroitement avec EDF, dont il ne conteste par le leadership de la filière nucléaire. Ce qui fait parfois grincer des dents en interne, certains se rappelant ses anciennes échauffourées avec l'opérateur historique. Le nouvel homme fort d'Areva a rencontré Henri Proglio début juillet.

Expert: contaminated beef poses no problem

An expert on nuclear medicine says eating meat contaminated with the radioactive substance cesium on a few occasions will not cause health problems.

Keigo Endo is the president of Kyoto College of Medical Science.

He says **Japan's safety limit for cesium is stricter than in the United States or Europe** where a large amount of meat is consumed.

Endo says eating 500 grams of meat containing the safety limit of cesium for at least 200 days would add up to 1 millisievert of radiation.

However, he says the government should work out measures immediately to prevent beef containing cesium above the safety limit from reaching the market including stepping up checks.

Monday, July 11, 2011 21:31 +0900 (JST)

High level contamination in reactor building found

The operator of the troubled Fukushima Daiichi nuclear power plant says it has detected **airborne radioactive materials up to 65 times above the government's standard inside the No. 2 reactor building.**

Tokyo Electric Power Company has been conducting an investigation inside the 3 reactor buildings and in areas surrounding the buildings since early this month.

On Monday, the plant operator said robots have detected airborne cesium-134 inside the No.2 reactor building ranging from 40 to 65 times above the government's standard.

The buildup of the radioactive air inside reactor buildings is believed to have originated from **explosions and steam leaking from the damaged reactors.**

TEPCO says that it's necessary to confirm the origin and amount of radioactive materials and to reduce the density of the contamination so that work can begin to bring the reactors under control.

High-level cesium detected at waste disposal facilities in Chiba

In this photo released by Tokyo Electric Power Co. (TEPCO), gray smoke rises from Unit 3 of the tsunami-stricken Fukushima Dai-ichi nuclear power plant in Okumamachi, Fukushima Prefecture, Japan, Monday, March 21, 2011. (AP Photo/Tokyo Electric Power Co.)

CHIBA, Japan (Kyodo) -- High levels of radioactive cesium have been detected in incinerated ashes at waste disposal facilities in Kashiwa, Chiba Prefecture, in apparent effects from the nuclear crisis at the Fukushima Daiichi power plant, the local municipal office said Monday.

At one waste disposal center in Kashiwa, up to 70,800 becquerels of radioactive cesium per kilogram were detected from ashes collected on June 24 and more than 60,000 becquerels were observed from ashes collected on July 1 and 2, the city office said.

Up to 48,900 becquerels of radioactive cesium were also detected at a facility for burying the ashes from waste disposal centers in the city, while a maximum of 9,780 becquerels were observed at another waste disposal center, the office said.

The figures far exceed the 8,000-becquerel per kilogram cap set by the state for waste disposal facilities to temporarily store such ashes.

(Mainichi Japan) July 12, 2011

Decontamination system fails again

Workers at the Fukushima Daiichi nuclear plant are still struggling to stably cool its reactors. Operator Tokyo Electric Power Company says a key system to decontaminate highly radioactive water has been halted yet again.

TEPCO says workers spotted a leak near a feeding pipe for a French-made device on Tuesday morning. TEPCO is trying to find out the cause and conduct repairs.

Water leaked from the same device on Sunday, forcing operations to halt.

The decontamination facilities are a key part of a system to treat and recycle radioactive water as coolant inside the disabled reactors. But the system has suffered one problem after another since going into operation at the end of June.

This could undermine TEPCO's target of stably cooling the reactors by July 17th as the first step in its schedule to bring the plant under control.

Tuesday, July 12, 2011 12:34 +0900 (JST)

Checking internal radiation of people begins

An atomic energy research facility in Ibaraki Prefecture has begun screening residents from neighboring Fukushima in northeast Japan for internal radiation.

Fukushima Prefecture plans to check its entire population of about 2 million to assess the effect of the accident at the Fukushima Daiichi nuclear plant. [but how at that rhythm ?]

It is now checking internal radiation levels for residents in the evacuation zone and areas near the nuclear plant as well.

Similar checks have also begun at the government-affiliated Japan Atomic Energy Agency in Tokai Village, Ibaraki where a total 28 pregnant women, parents and their small children from Namie Town arrived on Tuesday.

A piece of equipment called a Whole Body Counter will be used to determine if they have absorbed radioactive materials through food and drinks.

The facility will examine about 2,800 people from Fukushima through next month.

Takumaro Momose at the facility says he knows that people in Fukushima are fretting about internal radiation and that he explains to each person the details of their test results to help ease their anxiety.

Tuesday, July 12, 2011 14:41 +0900 (JST)

TEPCO prepares for nitrogen injection

The operator of the crippled Fukushima Daiichi nuclear power plant will begin fixing pipelines at the No. 3 reactor on Tuesday afternoon in preparation for injecting nitrogen into its container.

Tokyo Electric Power Company says workers confirmed last Friday that pipes could be connected to the container.

TEPCO plans to inject nitrogen into the container in an effort to avoid a hydrogen explosion. The utility has set a target of July 17th to complete the operation. Nitrogen was injected into the No. 1 reactor in April and No. 2 reactor in June.

The utility on Monday reported its plan to the Nuclear and Industrial Safety Agency and described safety measures to limit workers' radiation exposure.

TEPCO also told the agency how the injection will impact the container.[???

The company says it wants to begin the injection as soon as it obtains approval from the safety agency.

TEPCO also said that **6 workers have been exposed to a level of radiation higher than the 250-millisieverts emergency limit since the accident. It said the levels ranged from 308 to 678 millisieverts.**

Tuesday, July 12, 2011 03:29 +0900 (JST)

Nuclear crisis minister wants underground barrier built quickly

In this June 12, 2011 photo released on July 5, 2011 by Tokyo Electric Power Co., masked workers in protective outfits prepare to drop one of sliding concrete slabs into a slit of the upper part of the sluice screen for Unit 2 reactor at the tsunami-crippled Fukushima Dai-ichi nuclear power plant in Okuma, Fukushima Prefecture, northeastern Japan, in their effort to decrease the leak of radiation contaminated water to the ocean. (AP Photo/Tokyo Electric Power Co.)

Goshi Hosono, minister in charge of the ongoing nuclear crisis, suggested July 11 that the government should push ahead with the construction of an underground barrier to block the flow of highly contaminated water from the Fukushima No. 1 Nuclear Power Plant as soon as possible.

Construction of such a barrier will cost more than 100 billion yen, according to some estimates. Hosono suggested that the government should help the plant's operator, Tokyo Electric Power Co. (TEPCO), with the project.

"Can a private company such as TEPCO handle this itself? I think the government should move into action, even if that means going a step ahead," Hosono said.

Contaminated water has leaked from reactor and turbine buildings at the crippled nuclear plant. **To stop this water from spreading through underground water and flowing into the sea,** TEPCO plans to construct underground walls extending to a depth of 30 meters. Under its roadmap for bringing the nuclear crisis under control, which was revised in June, consideration of the best way to block the flow of contaminated water, as well as selection of a solution and construction, had been deemed "mid-term issues" after Step 2 of the roadmap that began in July and continues for three to six months.

"Construction of a barrier is an important process. We finished considering plans at an early stage of Step 2, and have started considering whether we can quickly begin construction," Hosono said.

In this June 30, 2011 photo released on July 5, 2011 by Tokyo Electric Power Co., sliding concrete slabs, seen above orange floats, are all set in the upper part of the sluice screen for Unit 2 reactor at the tsunami-crippled Fukushima Dai-ichi nuclear power plant in Okuma, Fukushima Prefecture, northeastern Japan, in TEPCO's effort to decrease the leak of radiation contaminated water to the ocean. (AP Photo/Tokyo Electric Power Co.)

The minister's comments, made at a meeting of the House of Representatives' special committee on restoration following the Great East Japan Earthquake and tsunami, came in response to an inquiry from Liberal Democratic Party lawmaker Masayoshi Yoshino.

(Mainichi Japan) July 12, 2011

Wife to seek work accident compensation over Fukushima plant worker's death

The wife of a man who died from a heart attack while working at the crippled Fukushima No. 1 Nuclear Power Plant plans to seek recognition of his death as a workplace accident, it has been learned.

The 60-year-old worker, Nobukatsu Osumi, a plumber from the Shizuoka Prefecture city of Omaezaki, died on May 14, after being dispatched to the nuclear power plant from a company cooperating with Toshiba Corp. to help bring the nuclear crisis under control.

Osumi's 53-year-old wife, a Thai national, plans to file to have his death recognized as a workplace accident eligible for compensation at the Yokohama Minami Labor Standards Inspection Office, which deals with Toshiba's workplace accident insurance, as early as this week.

Toshiba and other sources said that Osumi had experience working at the Hamaoka and Shimane nuclear power plants in the past. **From Toshiba's perspective he was a temporary employee for a construction company designated as a fourth-level subcontractor.**

In a shift between 6 and 9 a.m. from May 13, Osumi was involved in work that included laying pipes for a facility to treat waste at the plant. At about 6:50 a.m. the following day, while he was carrying a special saw, he complained that he felt unwell. He was eventually taken to a hospital in the Fukushima

Prefecture city of Iwaki, but shortly after 9:30 a.m. he was confirmed dead as the result of a heart attack.

During the course of his work at the plant he received only a small radiation dosage of 0.68 millisieverts, and it was judged his health was not affected by exposure to radiation. However, it was pointed out that there were deficiencies in the emergency care system for workers, as **it took more than two hours for Osumi to reach hospital from the time that he complained of feeling ill.** Since Osumi's death, Tokyo Electric Power Co. (TEPCO), the nuclear power plant's operator, has placed a doctor on standby for workers.

Neither Toshiba nor TEPCO have paid consolatory money or other compensation to Osumi's wife. Her lawyer has criticized their treatment as "cold."

"Mr. Osumi was working in a harsh environment wearing a mask and protective clothing. Their treatment of this worker, who was putting his life on the line in his work, is too cold."

A TEPCO representative said the company did not believe there was a strong connection between the work and Osumi's death. Toshiba's public relations office, meanwhile, commented, "The relationship between the work and the heart attack is unclear, and at this stage we cannot judge whether or not it was a workplace accident."

Noboru Yanagisawa, an emeritus professor in labor law at Yamaguchi University, said that workplace accident compensation should be granted to Osumi's case.

"With workplace accidents, problems emerge over the acknowledgement of whether psychological and mental ailments occurred in the course of the person's work or not, but work environments that grossly lack life-saving measures are also taken into consideration. It is difficult to determine whether the heart attack occurred due to the work this time, but it is clear that there were delays in life-saving measures, and this case should be recognized as a workplace accident."

(Mainichi Japan) July 12, 2011

Residents get together to decontaminate city after discovery of radiation hotspots

Radioactive pool water is decontaminated at Tominari Elementary School in Date, using tanks containing zeolite absorbents. (Mainichi)

FUKUSHIMA -- Residents in the Fukushima Prefecture city of Date have banded together to decontaminate the city after the discovery of radiation hotspots that led to 113 households being placed under special evacuation recommendations.

Their move comes in response to fears that the government system placing only certain households in the city under evacuation recommendations could create rifts in the local community.

The city of Date covers an area of about 265 square kilometers. In the wake of the crisis at the Fukushima No. 1 Nuclear Power Plant, many areas besides the city's radiation hotspots have shown high radiation levels, prompting the municipality to hammer out its own decontamination measures.

On June 27 a decontamination project team was formed, with Shunichi Tanaka of the Japan Atomic Energy Commission serving as an advisor and the Japan Atomic Energy Agency in Tokai, Ibaraki Prefecture, providing technical support.

From the beginning of this month, work to decontaminate Tominari Elementary School, which has a roll of 60 pupils, began. Water in the school's outdoor pool contained cesium with a radioactivity of 100 to 600 becquerels per kilogram, but the water was purified using zeolite absorbents, reducing the radiation to 20 becquerels per kilogram -- below the safety limit of 50 becquerels per kilogram set for seaside bathing spots. At the same time, officials confirmed that using electric planers to shave the surface of asphalt, cutting the grass on slopes and removing surface soil could reduce radiation to one-tenth of the original level.

The Date Municipal Assembly passed a supplementary budget including about 400 million yen for decontamination countermeasures, but due to limited funds the city started seeking volunteers on July 11. On July 16 and 17, the city will mobilize a large team of people to cut grass and remove surface soil. It hopes to open the school's pool on July 18.

"By having the cheerful voices of children return, we hope this will create a foothold for the city to recover," Date Mayor Shoji Nishida said.

About 200 people are needed to carry out the work on July 16 and 17. Volunteers can register at <http://www.fukushima.coop/> (Japanese language only).

(Mainichi Japan) July 12, 2011

TEPCO restarts decontamination system

The operator of the Fukushima Daiichi nuclear power plant has restarted a system to decontaminate highly radioactive water **after an 8-hour halt** to replacing a faulty part.

Tokyo Electric Power Company had stopped running the system on Tuesday morning after workers spotted a leak from a joint that connects a pipe. The pipe feeds chemicals to a French-made device designed to break down radioactive materials.

TEPCO says the original metal joint was corroded by the chemicals and that it has now replaced it with a stainless-steel part.

The original joint had been replaced with a polyvinyl joint only 2 days ago due to another leak.

The decontamination facilities are a key part of TEPCO's plan for treating and recycling radioactive water as coolant inside the disabled reactors.

But the system has suffered one problem after another, raising question about TEPCO's announced target of stably cooling the reactors by July 17th, the first step in its plan to bring the plant under control.

Also on Tuesday, TEPCO completed work to connect pipes for the injection of nitrogen into the containment vessel of the No. 3 reactor to prevent a hydrogen explosion.

The utility plans to start nitrogen injections in a few days after receiving approval from the government's Nuclear and Industrial Safety Agency.

Tuesday, July 12, 2011 19:35 +0900 (JST)

Press Release WISE/SOMO Report on uranium mining

Amsterdam, 12 July 2011

Uranium mines threaten African people and nature

Uranium exploitation leads to large-scale radiological and toxic contamination around many mining sites in Africa. Multinational mining companies remain largely unregulated and unaccountable, public participation in decision making regarding uranium mining is minimal, and long-term effects are insufficiently addressed. These are the findings of a report published today by the Dutch research organisations WISE and SOMO entitled *Uranium from Africa: Mitigation of uranium mining impacts on society and environment by industry and governments*.

Over the past year, the World Information Service on Energy (WISE) has conducted research in South Africa, Namibia, and the Central African Republic and has compared the situation in those countries with conditions in Canada and Australia, both of which are historically important uranium producing countries. The research involved extensive interviews with representatives of African governments, civil society, and five uranium mining companies: **France-based AREVA**, South African AngloGold Ashanti, English-Australian Rio Tinto, Australian Paladin, and Canadian First Uranium

The rising demand for uranium to produce nuclear energy has led to an increase of uranium mining activities in Africa in recent years. In countries such as Niger, Namibia, South Africa, the Central African Republic, Malawi, and Tanzania, companies have expanded their mines or are opening new mines.

Uranium mining is associated with high environmental impacts and human health risks. The costs of rehabilitation of the mining area are often many times higher than the total revenues derived during the mine's entire lifetime. Nevertheless, uranium mining operations are welcomed in many African countries due to the short-term economic benefits they provide.

The report describes how multinational uranium mining companies are generally not held accountable for their social and environmental performance at African operations, and how governments and populations are struggling with a lack of knowledge and means to exert influence over companies and to address irresponsible corporate behaviour. Public participation in decision making is minimal and protection of human rights is insufficient. Radioactive and toxic contamination of water, land, and air is often not effectively addressed.

The social and environmental conditions at uranium mines is an increasingly relevant issue given mounting pressure on electricity companies to take responsibility for the conditions in the commodity chains that supply fuel for generating electricity.

Fleur Scheele, researcher at WISE and author of the report: "The serious problems associated with uranium mines in Africa raise doubts about the genuineness of electricity companies' commitment to supply chain responsibility."

The report was carried out as part of a larger SOMO/WISE project on uranium mining in Africa that included the February 2011 publication of a study entitled *Radioactive Revenues: Financial Flows between uranium mining companies and African governments*. Both reports can be downloaded from www.somo.nl.

Direct link to the report: www.antenna.nl/wise/uranium.pdf

For more information, please contact Fleur Scheele at WISE: +31 20 612 63 68 or wiseuranium@antenna.nl

Gov't to set up body to study reactor decommissioning

TOKYO (Kyodo) -- The government asked its nuclear policy commission to set up a body to consider medium- to long-term steps for handling the troubled Fukushima Daiichi nuclear power plant after the current crisis is over, such as how to remove melted fuel and decommission the crippled reactors, a Cabinet minister said Tuesday.

The remarks came as plant operator Tokyo Electric Power Co. is expected to realize the stable cooling of troubled reactors later this month and move toward the next goal of stabilizing them by so-called cold shutdown, although the plant's key water treatment system again saw a leakage problem Tuesday.

Discussions of the kind have already begun centering on the Atomic Energy Commission, comprising five commissioners, but Goshi Hosono, minister in charge of nuclear accidents, said in a press conference in the morning he has asked the commission, an organ of the Cabinet Office, that discussions be conducted at a formal forum.

As for the melted nuclear fuel rods and spent fuel being left inside the plant, Hosono said, "We must find a way not to make Fukushima Prefecture the final disposal site. But I'm sorry for the people in Fukushima because (the fuel) will remain there for an extremely long time."

In this photo released by Tokyo Electric Power Co. (TEPCO), a small fire breaks out from facilities sampling seawater located a few dozen meters from Unit 4 inside the tsunami-crippled Fukushima Dai-ichi nuclear power plant in Okumamachi, Fukushima Prefecture, northeastern Japan, Tuesday morning, April 12, 2011. The

fire was put out soon and the ongoing cooling operations at the main units were not affected according to TEPCO. (AP Photo/Tokyo Electric Power Co.)

Efforts to restore the plant continued Tuesday, with a system to decontaminate highly radioactive water resuming operations in the afternoon after replacement of a leak-causing component, according to Tokyo Electric spokesman Junichi Matsumoto.

Designed to recycle decontaminated water as a coolant for the Nos. 1 to 3 reactors, the system must run smoothly to eventually contain the ongoing nuclear crisis triggered by the March 11 massive earthquake and tsunami. It also reduces the massive amount of highly radioactive water accumulating on the plant premises as a side effect of injecting water to cool the reactors.

The latest leakage was found in the installation developed by France's Areva SA. After similar trouble detected Sunday, Tokyo Electric had replaced the component from a plastic one to an iron one, apparently to no avail.

Matsumoto said during a joint press conference with Hosono and other government officials that workers used a component made of stainless steel on Tuesday to address the trouble.

Meanwhile, workers also prepared to inject nitrogen into the No. 3 reactor to reduce the risk of further hydrogen explosions. Nitrogen is already being injected into the Nos. 1 and 2 reactors.

Hosono said he was happy that workers finished installing a hose to inject nitrogen into the No. 3 unit by overcoming the high radiation level seen inside the building.

(Mainichi Japan) July 13, 2011

TEPCO halts reactor cooling to replace hose

Tokyo Electric Power Company says it has resumed cooling of the **No. 5 reactor** at the Fukushima Daiichi nuclear power plant after a brief stop to replace a hose.

TEPCO said it had stopped cooling at 6:30 AM on Wednesday to replace a vinyl hose feeding seawater into the cooling system. It says the hose was touching the edge of a concrete structure and could have ruptured.

The utility says cooling resumed shortly before 11 AM.

It says the reactor's temperature rose more than 6 degrees during the repair, to 49.3 degrees Celsius, but the cooling process remained stable.

The utility has been checking all the hoses at the No. 5 reactor since a leak earlier this month forced it to halt cooling for more than 3 hours.

Wednesday, July 13, 2011 13:02 +0900 (JST)

Moms set up network to protect kids from radiation

Japanese mothers have set up a nationwide network to protect their children from food contaminated with radioactive substances.

About 450 mothers and others from across the country gathered to kick off the organization in Tokyo, on Tuesday.

A mother from Fukushima said that the national and local governments simply repeat that food on the market is safe, but she cannot trust their words. She said the group should urge prefectural governments to take sufficient measures to ensure children can eat safe food.

Participants were then divided into groups based on the areas they are from, and discussed their worries.

A mother who lives near Tokyo said she hopes members will share information to protect their children from radiation exposure.

Another mother said she now knows that many parents share their worries. She said that she hopes their efforts will gain momentum and bring about change.

Tuesday, July 12, 2011 20:37 +0900 (JST)

New cooling devices set for Fukushima fuel pools

The operator of the troubled Fukushima Daiichi nuclear plant is to set up two more cooling systems for reactors' spent fuel storage pools.

The planned devices are to start operating in late July at the No. 4 reactor pool and in early August at the No. 1 pool.

Spent fuel rods are currently kept in the storage pools of each of the 4 reactor buildings. The No. 2 and No. 3 reactor buildings already have cooling systems and water temperatures in these pools is at the normal level of below 40 degrees Celsius.

The Nuclear and Industrial Safety Agency has instructed Tokyo Electric Power Company to report details of the installation plan by Wednesday.

TEPCO also needs to report the earthquake-resistance of the new systems and measures to prevent water leakage.

Wednesday, July 13, 2011 10:25 +0900 (JST)

Fukushima to conduct radiation tests on all beef in evacuation zones before shipping meat

FUKUSHIMA -- The prefectural government has decided to kill all beef cows kept at about 260 livestock farms in evacuation zones in the prefecture and conduct radiation tests on them locally before shipping their meat, officials said.

The decision follows revelations that beef cows contaminated with high levels of radioactive cesium were shipped from a livestock farm in Minamisoma, Fukushima Prefecture.

The Fukushima Prefectural Government has deemed that the measure is indispensable to alleviate consumers' concerns and prevent groundless rumors that beef produced in the prefecture is contaminated with radiation.

Livestock farms in Fukushima Prefecture ship approximately 33,000 beef cows a year. Of them, only 10 percent are processed into meat inside the prefecture, while the remainder are shipped out of the prefecture before being slaughtered. Most of the cows are sent to markets in the Tokyo metropolitan area.

Shortly after the crisis at the tsunami-hit Fukushima No. 1 Nuclear Power Plant, the prefectural government had asked the Health, Labor and Welfare Ministry and the Agriculture, Forestry and Fisheries Ministry to create a system in which municipalities that have slaughterhouses can conduct radiation tests on all cows after they were shipped out of the prefecture.

However, the prefecture has recently been forced to change its initial policy because **it is extremely difficult to ask local governments, which are preoccupied with conducting radiation tests on fruit and vegetables, to examine beef cows as well.**

There are also other challenges. A slaughterhouse in Koriyama is the sole such facility in the prefecture, and it can process only 36 cows a day. The prefectural government intends to consult with the industry organization over how to create a system to ensure that all the beef cows can be slaughtered and that radiation tests can be conducted on them in the prefecture before being shipped.

Moreover, since **there is not enough equipment to detect and measure radioactive substances in the prefecture,** the prefectural government is poised to commission the National Institute for Agro-Environmental Sciences to conduct radiation tests on some of the beef cows.

PM Kan wants to wean Japan from nuclear power

By [Kiyoshi Takenaka](#) and [Yoko Kubota](#)

TOKYO | Wed Jul 13, 2011 7:03am EDT <http://www.reuters.com/article/2011/07/13/us-japan-nuclear-kan-idUSTRE76C19O20110713>

(Reuters) - Japanese Prime Minister Naoto Kan said on Wednesday the Fukushima nuclear crisis had convinced him that [Japan](#) should wean itself from nuclear power and eventually have no atomic plants.

The radiation crisis at Tokyo Electric Power Co's Fukushima plant, triggered by the March 11 earthquake and tsunami, has sparked debate about the role of nuclear power in quake-prone, resource-poor Japan, as well as concerns about power shortages with 35 of the nation's 54 reactors now halted.

"Given the enormity of the risks associated with nuclear power generation, I have realized **nuclear technology is not something that can be managed by conventional safety measures alone,**" Kan told a news conference. "I believe we should aim for a society that is not dependent on nuclear power generation."

The Fukushima plant is still leaking radiation four months on, although Kan said workers were on track to achieve a target of stable cooling of the reactors by mid-July and that the government hoped to move forward its deadline of putting the crippled reactors into cold shutdown by January.

Kan said it was premature to set a time frame for achieving the goal of a nuclear power-free society but said it would be a gradual process.

The unpopular prime minister has become increasingly sensitive to public concern about nuclear power, but whether he oversees an overhaul of energy policy is in doubt since he has promised to resign, although he has not said when.

Kan also said Japan would be able to avoid summer and winter power shortages through energy conservation efforts and companies' in-house power supplies, despite the large number of reactors now off-line for inspections or other work.

He said the government would take steps to alleviate the impact on consumers and businesses from the short-term loss of nuclear power due to idled reactors, but gave no details.

RISKS OF ZERO NUCLEAR POWER

Nuclear energy accounted for about 30 percent of Japan's power supply before the March 11 disasters crippled Tokyo Electric's Fukushima plant, 240 km (150 miles) north of the capital. That ratio slipped to 18 percent in June.

Nuclear power advocates have warned that abandoning atomic energy would itself entail risks, although of a different kind.

"Phasing out nuclear power is not risk-free," said Tatsujiro Suzuki, vice chairman of the Japan Atomic Energy Commission, which advises the government on nuclear policy.

"Probably the immediate risk would be increased consumption of fossil fuels that would lead also to CO2 emissions increases and other air pollution," Suzuki told Reuters in an interview.

Japan has set a target for 2020 of reducing greenhouse gas emissions by 25 percent from 1990 levels.

"Another possible risk would be energy prices could go up and possibly dependence on the Middle East or other fossil fuel exporting countries," Suzuki said.

"Having a vision of being nuclear energy-free is one thing. How to achieve it is another thing. It is very difficult to phase out nuclear power in a real sense," he said.

Economics Minister Kaoru Yosano, an ardent supporter of nuclear power, echoed concerns about economic costs, telling a news conference that substituting fossil fuel for atomic energy would be equivalent to a large rise in Japan's corporate tax and slice several trillion yen (tens of billions of dollars) off gross domestic product.

But he gave no time frame for that prediction.

Energy experts said Japan would have to boost fuel imports to make up for any short-term decline in nuclear power.

"It takes time to reduce reliance on nuclear power and replace it with alternatives, maybe a span of 10 years or so," said Koki Ota, senior economist at Sumitomo Shoji Research Institute, adding that demand for low-sulphur waxy residue and gas imports would strengthen the most.

Kan, who has come under fire for his handling of the nuclear crisis, defended his introduction of stress tests for reactors to soothe public safety concerns but apologized once again for the apparent abruptness of the move.

He said that idled reactors that completed the first stage of the two-stage stress tests could resume operations if experts and relevant cabinet minister agreed.

Last week's decision to introduce the tests, simulations to confirm nuclear plants' safety and check their ability to withstand extreme events, fanned corporate worries about power shortages if idled reactors stay off-line, and outraged some local officials who had been ready to approve restarts after earlier government safety assurances.

Kan said he was not thinking about calling a snap election over energy policy and sidestepped a question on when he would quit.

Among the conditions he has previously cited for resigning is passage of a bill that would promote renewable energy sources such as solar and wind power. (\$1 = 78.740 Japanese Yen)

Wastewater filters still working below target

A system installed to recycle radioactive wastewater at Fukushima Daiichi nuclear plant continues to work below its target capacity, due to a series of filter problems.

The plant's operator, Tokyo Electric Power Company, started running the system on June 27th to decontaminate radioactive wastewater pooled in reactor buildings, and send it back into the reactors as coolant.

The utility aims to have the system's decontaminating device working at 80 percent capacity.

However, the operating rate for the first week was below target. During its second week, the system was only operating at **73 percent capacity**.

Tokyo Electric blames the failure to reach the target on repeated problems with filters used to remove radioactive substances.

The decontaminating device was halted again on Wednesday afternoon because of leaks.

The utility considers the system to be critical in cooling the reactors and bringing them under control in line with the timetable it has set.

Wednesday, July 13, 2011 19:22 +0900 (JST)

Quake damage to turbine blades found at Tokai

Damage to turbine blades, apparently caused by the March 11th earthquake, has been found at a nuclear power plant in Ibaraki Prefecture, eastern Japan.

The Tokai Daini plant, about 100 kilometers north of Tokyo, automatically shut down in the quake. The operator of the plant, Japan Atomic Power Company, has been checking the plant closely since May in a regular checkup scheduled to last 6 months.

It says it discovered friction marks on the blades and other parts of the reactor's turbines.

The company believes the damage was caused by the March 11 quake as similar marring had been reported in another plant in Niigata Prefecture in the wake of an earthquake in 2007.

The utility says some parts were also found missing from a device that injects coolant into the reactor. It also discovered cracks in equipment attached to the upper parts of the reactor.

It says it is investigating whether those defects were also caused by the March quake.

In the giant quake, the Tokai Daini plant lost its outside power sources, and had to rely on emergency generators until regular power returned.

Earlier this month the government nuclear safety body found the level of quake-resistance of the electrical equipment at the plant was below the standard set by power companies.

Wednesday, July 13, 2011 22:26 +0900 (JST)

Utility's campaign to outvote opposition to atomic plants worked

FUKUOKA (Kyodo) -- Kyushu Electric Power Co.'s email campaign mobilizing utility and nuclear power plant employees apparently worked in drawing more e-mail opinions supporting the restart of reactors than those against in a TV program aired in late June, utility sources said Wednesday.

The TV program received a total of 286 opinions in support by e-mail and fax, while those opposed totaled 163. While the margin was 123, the utility sources said around 130 people associated with the utility posted their opinions and most of them were thought to be in support.

Kyushu Electric Power has also identified its former Executive Vice President Mamoru Dangami as having instructed his deputy to launch a campaign to send e-mails to the TV program in favor of restarting its nuclear reactors, the sources said.

The utility will admit its organized e-mail campaign in a report that it will submit to the Ministry of Economy, Trade and Industry possibly on Thursday, the sources said.

Dangami instructed Akira Nakamura, deputy head of the utility's nuclear power control department, to enliven discussions on the TV program, which was designed to win support for restarting two reactors after regular checks at the Genkai nuclear plant in Saga Prefecture, the sources said.

Nakamura then conveyed the instruction to his deputy who asked Kyushu Electric employees, including those at affiliates of the company, to send e-mails supporting the restart for the TV program aired June 26, they said.

Kyushu Electric had earlier denied an organized e-mail campaign, indicating it was initiated voluntarily by a senior employee.

Dangami resigned as executive vice president in charge of nuclear plants in late June.

The TV program was aimed at paving the way for restarting Genkai and other nuclear reactors after regular checks, but they had not been restarted due to the crisis at the Fukushima Daiichi nuclear plant caused by the March 11 earthquake and tsunami in northeastern Japan.

(Mainichi Japan) July 14, 2011

Kan seeks shift from nuclear power

Prime Minister Naoto Kan says Japan should gradually decrease its dependency on nuclear energy, and aim toward creating a society that can get along without it.

Kan announced the shift in the country's energy policy at a news conference in Tokyo on Wednesday.

Kan said the Fukushima nuclear plant crisis that followed the March 11th disaster made him realize that nuclear technology could become uncontrollable.

He added that until the accident, he had backed the use of nuclear energy as long as it was safe.

Referring to restarting idled reactors, Kan said his government could make a final decision on the

restart, if government assessments find them to be safe.

On a positive note, Kan said his ministers have told him that power supplies for peak consumption this summer and the coming winter will be adequate, thanks to nationwide power-conservation efforts.

He also said that the government will consider increasing the use of natural gas to secure electric power supplies for next year and beyond.

Presently nuclear generated power accounts for about 30 percent of Japan's electricity.

Wednesday, July 13, 2011 20:14 +0900 (JST)

Mixed reaction greets shift from nuclear power

Prime Minister Naoto Kan's new initiative to reduce Japan's dependence on nuclear power has drawn both support and criticism.

Kan announced the shift in nuclear and energy policy on Wednesday.

He said Japan should gradually but systematically reduce its dependence on nuclear power and work toward becoming a society that can do without nuclear energy.

The announcement drew a positive response from the governing coalition as well as some opposition lawmakers.

They welcomed the idea of reducing nuclear dependence and promoting renewable energy sources.

But Economic and Fiscal Policy Minister Kaoru Yosano says the possible economic impact of such a policy shift should be taken into account.

The Japan Business Federation is also cautious, saying nuclear plants continue to play an important role in the stable supply of electricity.

Following the prime minister's initiative, the government will begin a review of its basic energy policy, which is based on building more nuclear reactors.

An energy and environmental panel made up of Cabinet ministers will first make a list of issues to be studied to reduce nuclear dependency.

Thursday, July 14, 2011 10:22 +0900 (JST)

Kyushu Electric delays restart of Sendai reactor

Kyushu Electric Power Company on Thursday announced the postponement of the restart of operations of the Number One nuclear reactor at its Sendai plant in the southwestern prefecture of Kagoshima,

citing local opposition.

The reactor was initially scheduled to resume operations in late July.

A regular checkup on the reactor began in May and has been completed.

The utility cited as another reason a lack of a timetable for the central government's plan to carry out additional safety assessments called "stress tests" on nuclear plants.

The mayor of Satsumasendai City, where the plant is located, says one condition for the restart would be the restart of operations at the Genkai nuclear power plant in Saga Prefecture.

Kagoshima Governor Yuichiro Ito has demanded the central government hold a briefing on the issue for local residents.

The Number 2 reactor at the Sendai plant is also scheduled to stop operations for regular checks in September.

Analysts say electric power supplies for the Kyushu region in the southwestern part of Japan could be affected when consumption peaks in the summer.

Thursday, July 14, 2011 16:59 +0900 (JST)

Kansai Power to halt more than half its reactors

Kansai Electric Power Company says it will temporarily shut down 2 nuclear power reactors in Fukui Prefecture next week for regular inspections.

The decision will leave the operation of a total of 6, or over half the utility's 11 nuclear plants, suspended.

The company announced on Thursday that the No.4 reactor of its plant in Takahama Town will be brought to a halt for regular inspections on July 21st, and the No.4 reactor of the plant in Oh Town, on July 22nd.

Regular inspections are nearly complete at 2 other reactors. But the government's plan to introduce safety stress tests for the nation's nuclear plants leaves it unclear when they can be brought back on line.

To avoid power shortages in high summer, the utility will continue to call on households and companies to cut power use by around 15 percent, as well as stepping up efforts to boost supply.

Thursday, July 14, 2011 18:24 +0900 (JST)

Kansai Power to shelve MOX fuel plan in Takahama

Kansai Electric Power Company has postponed a plan to introduce recycled plutonium fuel at a reactor in its nuclear power plant in Fukui Prefecture.

The utility told NHK on Thursday that a lack of local understanding means it cannot proceed with feeding the No.4 reactor of the Takahama plant with plutonium-uranium mixed oxide, or MOX fuel, in regular checkups starting on July 21st.

The revelation came shortly after the Mayor of Takahama Town, Yutaka Nose, told reporters that lack of transparency in the government's energy policy in the wake of the nuclear crisis makes it impossible to understand why the reactor needs MOX fuel.

Consent from Fukui Prefecture and Takahama Town is vital for the utility to carry out the plan.

The No.4 reactor was supposed to become the fifth in Japan to introduce recycled nuclear fuel, after the company began using MOX at the No.3 reactor of the plant in January.

Two power plants in Saga and Ehime Prefectures that had already used MOX fuel are not in operation.

The No.3 reactor of the Takahama plant, the only working reactor on MOX fuel, is scheduled to be suspended for regular checkups early next year.

Kansai Electric Power Company's decision is likely to affect the so-called "pluthermal" project, the pillar of the nation's nuclear recycling policy.

Thursday, July 14, 2011 19:49 +0900 (JST)

Fukushima plant suffers a leak in water filtering

A system for decontaminating and recycling radioactive wastewater at the Fukushima Daiichi nuclear power plant has been halted again after operating in fits and starts.

Plant operator, Tokyo Electric Power Company, found a leak through a broken plastic joint in a French-made facility on early Wednesday afternoon, **forcing a shutdown for more than a day.**

As of late Thursday afternoon, Tokyo Electric has not finished replacing the damaged polyvinyl chloride joint. The PVC joint, which was the cause of earlier leaks, is thought to be structurally too weak.

The company says the latest shutdown does not affect its operation to pump coolant into the reactors.

The system is designed to filter radioactive wastewater pooled in the basement of reactor buildings, and then sent the cleaned water back into the reactors as coolant.

A series of troubles since the start of operations in June has resulted in operation rates of only about 73 percent during the past week, far below the targeted 90.

Tokyo Electric considers the system critical in meeting its target of putting in place a stable reactor cooling system by July 17th. The date would mark the end of phase one in a timetable it has set for bringing the reactors under control.

Thursday, July 14, 2011 19:26 +0900 (JST)

Toshiba develops nuclear decontamination system

Japanese electronics maker Toshiba has developed a system to decontaminate radioactive wastewater at the Fukushima Daiichi nuclear power plant **from early August.**

The system, nicknamed **Sarry**, was shown to media at a plant in Yokohama on Thursday. It consists of **a series of 14 tanks, each 1.4 meters wide and 3.6 meters high.**

Minerals put inside the tanks are to absorb radioactive cesium and strontium and reduce levels of radioactivity in contaminated water by a factor of about one million.

A decontamination system in place at the Fukushima plant since June has been accident-prone and running at 73 percent capacity, far below the target of 90 percent.

The new equipment is expected to be used in parallel with or as a supplement to the existing one.

A Toshiba official says the firm made the new system simpler than the existing one by studying problems it developed.

Thursday, July 14, 2011 19:26 +0900 (JST)

TEPCO urged to tighten workers' radiation control

Japan's Nuclear and Industrial Safety Agency has urged the operator of the Fukushima Daiichi nuclear plant to tighten controls on workers' radiation exposure.

About 3,000 workers are struggling daily at the plant to contain the nuclear crisis.

The safety agency has been inspecting Tokyo Electric Power Company's measures to protect them from exposure to radiation.

The agency says it has found 8 areas of concern and ordered TEPCO on Wednesday to take appropriate measures.

The agency said that **TEPCO lacks information about subcontracting employees** and ordered the company to boost the number of safety managers for such workers.

It also urged the utility to **provide more full-face protective masks and make sure that plant workers wear them properly.**

Since the nuclear crisis began in March, 6 workers have been exposed to radiation doses above the allowable emergency limit of 250 millisieverts. **About 1,500 have still to receive medical checks for exposure to radiation.**

Thursday, July 14, 2011 07:51 +0900 (JST)

Nitrogen injection starts at No. 3 reactor

The operator of the Fukushima Daiichi nuclear plant has started injecting nitrogen into the plant's No. 3 reactor's containment vessel to prevent a hydrogen explosion.

The Tokyo Electric Power Company **started the procedure on Thursday evening** after Japan's Nuclear and Industrial Safety Agency confirmed the plan's safety.

Tokyo Electric had already begun injecting nitrogen into the plant's No. 1 and 2 reactors. The work at the No. 3 reactor was delayed due to high radiation levels.

Nitrogen injection is essential for the utility to complete the first step of its plan to bring the plant under control by the target date of July 17th.

Thursday, July 14, 2011 21:52 +0900 (JST)

TEPCO deadline looms

The operator of the Fukushima Daiichi nuclear plant is aiming to meet its first stage deadline to bring the plant under control by injecting nitrogen into its No.3 reactor containment vessel. But a problematic wastewater system may delay their goal.

The Tokyo Electric Power Company **started the injection on Thursday evening** to prevent a hydrogen explosion.

The utility had already begun the procedure at the plant's No.1 and 2 reactors, but the work was delayed due to high radiation levels.

The injection is essential for the utility to complete the first step of its plan to bring the plant under the control by the target date of July 17th.

But a French-made system installed to recycle radioactive wastewater continues to work below its

target capacity. The device is meant to decontaminate radioactive wastewater and send it back into the reactors as coolant. Tokyo Electric says the problem has been malfunctioning filters.

The utility plans to introduce a newly developed device as an alternatives in August.

Friday, July 15, 2011 02:16 +0900 (JST)

TEPCO starts injecting nitrogen into No. 3 Fukushima reactor

In this July 3, 2011 photo released by Tokyo Electric Power Co., iron sheets that protect workers from radiation are placed on the ground floor of the Unit 3 reactor building at the tsunami-crippled Fukushima No. 1 Nuclear Power Plant in Okuma, Fukushima Prefecture, northeastern Japan. The photo was taken through a window of a fork lift. (AP Photo/Tokyo Electric Power Co.)

TOKYO (Kyodo) -- The operator of the crippled Fukushima Daiichi nuclear power plant said Thursday it started to inject nitrogen into the No. 3 reactor to reduce the risk of further hydrogen explosions, a move marking further progress toward containing the four-month-old nuclear crisis.

The injection of the substance into the plant's three troubled reactors has been one of the key goals Tokyo Electric Power Co. has intended to achieve by mid-July, and the No. 3 reactor was the only remaining one that was not receiving the inert gas.

As Tokyo Electric has also started to operate a new system that enables water to circulate around the three reactors to stably keep the nuclear fuel inside cool, **the utility and the government believe they are basically moving ahead with the restoration work as planned in a roadmap.**

Under the roadmap, the utility, known also as TEPCO, would aim to **bring the crippled reactors to a stable condition by mid-July as a first step,** and to a further stable "cold shutdown" by January at the latest as a second step.

TEPCO and the government will announce a new roadmap Tuesday that will highlight their work schedule to be implemented during the second step and beyond.

Nitrogen injection into the reactor's primary containment vessel is important to prevent an explosion from occurring inside the vessel, which may lead to the release of massive amounts of radioactive substances outside. The step is intended to keep the ratio of hydrogen inside the vessel to a certain low level.

The move may cause radioactive substances to further leak out from the containment vessel, but the utility said that the amount would not be at a level to affect the surrounding environment.

Nonetheless, TEPCO decided to strengthen radiation monitoring inside the plant.

Hit by a magnitude-9.0 earthquake and massive tsunami on March 11, the six-reactor Fukushima complex lost nearly all of its power sources, and thus the cooling functions of many of the reactors and spent fuel pools.

Hydrogen explosions occurred at the Nos. 1 and 3 units in the early days of the nuclear crisis, blowing off the walls and roofs of the buildings housing the reactors and leading to the release of radioactive materials into the environment.

(Mainichi Japan) July 14, 2011

TEPCO again stops key reactor cooling system

The operator of the Fukushima Daiichi nuclear power plant continues to struggle in its efforts to stably cool the facility's reactors. Workers have again halted a key wastewater system after discovering that it was operating below capacity.

Early Friday morning, Tokyo Electric Power Company stopped the system, which decontaminates and recycles radioactive wastewater. The system had resumed operation only a day before to repair a leak.

TEPCO says it found that even after the repair, the system was able to treat only 37 tons [????] of contaminated water per hour, which is 20 percent below target. The company is now inspecting the cause.

TEPCO says the latest shutdown had not led to a rise in fuel rod temperatures, as cooling operations are continuing with water that had previously been decontaminated.

Steady operation of the water treatment system is critical to achieving the company's goal of having a stable reactor cooling system in place by Sunday. That would mark the end of the first phase of bringing the reactors under control.

Meanwhile, on Thursday night, TEPCO began injecting nitrogen into the No.3 reactor's containment vessel to prevent a hydrogen explosion.

It says the measure has not led to a rise in radiation levels around the facility.

Friday, July 15, 2011 12:51 +0900 (JST)

Finding that radiation-tainted straw was produced far from nuclear plant causes shock

Revelations that radiation-contaminated rice straw used as feed for beef cattle was produced far away from the crippled Fukushima No. 1 Nuclear Power Plant have sent shockwaves through the livestock farming community in Fukushima Prefecture.

Consumers have also been filled with a sense of growing distrust in the government over delays in responding to the problem of radiation-tainted beef.

Forty-two beef cows that ate rice straw contaminated with radioactive cesium were found to have been shipped from a livestock farm in the Fukushima Prefecture town of Asakawa from April 8. The rice straw had been supplied by a farmer in Shirakawa, about 75 kilometers away from the tsunami-hit nuclear power station.

"It's unbelievable that this (contamination) occurred in an area so far away from the nuclear plant," said a 34-year-old man who has run a livestock farm in Minamisoma, Fukushima Prefecture, for nearly 10 years.

On July 8 the government asked livestock farmers in the city to refrain from shipping beef.

"Fukushima-produced beef cows will no longer sell unless we switch to feed produced outside the prefecture and suspend shipments of beef cows until the safety of all feed produced in the prefecture is confirmed," the Minamisoma farmer said.

Officials with the local governments of areas to which the cows had been shipped were busy confirming meat distribution routes until late on July 14.

Top officials of the Tokyo Metropolitan Government have consulted with officials in Tokyo's Bureau of Social Welfare and Public Health over how to conduct follow-up surveys. Thirteen of the cows had been shipped to Tokyo by June 16.

The metropolitan government had just finished an investigation on July 13 into the distribution routes of six other contaminated beef cows which had been shipped from Minamisoma.

"We have no choice but to diligently track down tainted beef that has been marketed," said a senior official.

Of the 42 cows shipped from Asakawa, 32 have been sent to slaughterhouses in Tokyo, Yokohama and Chiba -- causing unrest among residents of the metropolitan area.

Keiko Endo, a 68-year-old woman who was shopping at a supermarket in Nakano Ward, Tokyo, expressed anger at the government's slow response to the case. "I buy goods at store shelves, believing that they are safe. I wonder why the government failed to check the safety of cows before their meat was shipped," she said.

A 40-year-old housewife who has 12- and 7-year-old children expressed worries about the safety of domestic meat while shopping at a supermarket in Mihama Ward, Chiba. "If something like this repeatedly happens, you become increasingly worried about food safety," she said. "I'll choose Australian meat for the health of my children."

At the same time, some consumers have expressed sympathy with farmers in Fukushima Prefecture who have been affected by the crisis at the crippled nuclear power station.

"I lately choose not to eat beef at barbecue restaurants. But I feel sorry for Fukushima people," said 74-year-old Akiko Suwabe, a housewife living in Tokyo's Nakano Ward.

"I don't think the farmer in question shipped the rice straw as feed while knowing it was contaminated with radiation. Experts say, 'If you eat the beef, it won't pose an immediate threat to your health'," said a 63-year-old woman from Chiba. "Consumers' overreaction will only make farmers suffer."

The livestock farm in Asakawa that shipped the 42 cows expressed an apology for the incident in an interview with the Mainichi Shimbun.

"I'm really sorry for this. I've been losing sleep since yesterday. I'm acquainted with the Shirakawa farmer who sold the rice straw to me," he said. "I can't immediately comment on the matter any further because I haven't resolved my feelings."

(Mainichi Japan) July 15, 2011

Disaster-hit Miyagi town questions dependence on nuclear money

ONAGAWA, Miyagi -- Four months after the Great East Japan Earthquake and tsunami devastated the coastal town of Onagawa, Miyagi Prefecture, collapsed ferroconcrete buildings are still visible and the middle of town, once replete with rows of shops and houses, is filled with debris.

Facing the disaster's aftermath, the Miyagi prefectural election committee announced July 7 that it would be difficult to hold a postponed prefectural assembly election by Sept. 22, as stipulated under a special law.

Onagawa itself put off a town assembly election originally scheduled for April in conjunction with many other local elections across the country. Five town election committee members have been busy dealing with the aftermath of the March 11 disaster and have had a hard time compiling a list of eligible voters.

Onagawa Mayor Nobutaka Azumi's term of office will expire on Sept. 18 but there are no prospects for a mayoral election either.

During a public hearing on the town's reconstruction plan at the prefectural Onagawa High School on May 27, some town residents asked why the town's reconstruction scheme made no mention of the Onagawa Nuclear Power Plant.

The nuclear power plant run by Tohoku Electric Power Co. came to a sudden halt due to the disaster. It is reachable from the heart of the town in about 30 minutes by car and is located in the middle of the Oshika Peninsula.

The nuclear power plant began commercial service in 1984 and created as many as 2,000 jobs. The town reaped huge benefits from the plant in fixed property tax and subsidies based on three electric power laws including the Electric Power Development Promotion Law.

Onagawa's total revenue in fiscal 2009 came to about 6.4 billion yen. The so-called "nuclear power money" including the fixed property tax and subsidies based on the three laws accounted for 65 percent of the revenue -- a national record.

The deep-pocketed town built a sports park, which is now being used as an evacuation center, various tourism spots, a hospital and other buildings.

The subsidies also helped to maintain and manage those facilities and pay salaries for nurses and nursery staff. "We could draw up a budget thanks to nuclear power money," a senior town official said.

The March 11 disaster struck the town hard, with the fisheries industry, the town's key industry, suffering catastrophic damage. The town is certain to face a big drop in revenue, and though risks associated with the Onagawa nuclear power plant have risen due to the ongoing crisis at the Fukushima No. 1 Nuclear Power Plant the town is likely to rely more on nuclear power money.

But the Fukushima crisis is changing residents' attitudes toward nuclear power.

"I can no longer say I wholeheartedly welcome the nuclear power plant," said a 61-year-old housewife living along the coast near the Onagawa Nuclear Power Plant.

Her son has worked at the Onagawa plant for more than 20 years instead of inheriting his family's fishing business. Debate on a possible graduation from nuclear energy makes him uneasy.

Incumbent town assemblymen are noticing a change in public sentiment toward nuclear power.

"If we do not call for an end to nuclear power, when are we going to do it? We have to prepare a reconstruction plan for the town without the nuclear power plant," town assemblyman Shigeru Abe, 46, says.

But a senior town official warned, "If there is debate on the pros and cons of the nuclear power plant, restoration and reconstruction may be delayed."

Seiro Kimura, a 66-year-old, six-term assemblyman and speaker of the town assembly, commented, "I never talked about nuclear power during past election campaigns. But I honestly wonder if it is OK to build things that man cannot control."

The 14-member town assembly is also scrambling to deal with the issue of nuclear money which has been the backbone of the town's budget.

(Mainichi Japan) July 15, 2011

Monju fast-breeder reactor project may be reviewed

Japan's science minister has suggested that the government may have to abandon the project to develop an experimental fast-breeder nuclear reactor.

Yoshiaki Takaki told reporters on Friday that it is natural to discuss the future of the Monju project in light of the crisis at the Fukushima Daiichi nuclear plant.

He said the issue of whether to continue or abandon Monju must be discussed in the context of Japan's overall energy policy.

The government regards the fast-breeder reactor as Japan's next-generation nuclear power plant and hope to put it into practical use in about 40 years.

Monju, located in Tsuruga City, Fukui Prefecture, has been suspended since last August due to a technical problem. The trouble occurred only 3 months after Monju resumed operation in May last year following a 14-year shutdown caused by a leakage of sodium coolant in 1995.

Friday, July 15, 2011 14:58 +0900 (JST)

Science minister says gov't will mull halting Monju prototype reactor project

<http://mdn.mainichi.jp/mdnnews/news/20110715p2g00m0dm104000c.html>

TOKYO (Kyodo) -- Science minister Yoshiaki Takaki indicated Friday that the government will consider suspending the development of the prototype fast-breeder reactor Monju in the wake of the country's worst nuclear crisis that continues at the Fukushima Daiichi power plant.

Whether to halt development of the advanced power reactor is "one issue" to be determined when Tokyo comes to review its nuclear energy policy, Takaki said at a regular press conference.

"The accident (at the Fukushima plant) is serious. It's only natural to discuss" matters including the suspension of Monju located in Tsuruga, Fukui Prefecture, in central Japan, he added.

Meanwhile, Fukui Gov. Issei Nishikawa telephoned Takaki in protest after hearing news reports about the minister's remarks.

Nishikawa told reporters in Tsuruga that the science minister denied making such remarks, quoting the minister as telling the governor that he "would not say such a thing without listening to what the local people have to say."

A top official at the Fukui prefectural government said the local government is checking the details of Takaki's remarks, while another official said the remarks came as no surprise as Prime Minister Naoto Kan has called for a society free from dependence on nuclear energy.

Unlike regular light-water reactors fueled by uranium, the Monju reactor, operated by the Japan Atomic Energy Agency, runs on an oxide mix of plutonium and uranium, or MOX, made from spent nuclear fuel from existing plants.

The reactor first achieved criticality in 1994, but was shut down due to a serious accident involving a leak of sodium coolant and a resulting fire in 1995.

Monju resumed operations in May 2010 after being idled for 14 years and five months, but the launch of full operations was delayed again as a device in the reactor accidentally fell inside the vessel in August that year. The agency removed the device in June.

In the fiscal 2011 white paper on science and technology, approved by the Cabinet on Tuesday, the Ministry of Education, Culture, Sports, Science and Technology deleted a sentence saying that it will realize the establishment of a fast-breeder reactor, backpedaling on its drive for research and development on nuclear power.

(Mainichi Japan) July 15, 2011

TEPCO checking for gas leak from No. 3 reactor

The operator of the Fukushima Daiichi nuclear power plant is checking for gas leaks in the No. 3 reactor, into which nitrogen is being injected to prevent a hydrogen explosion.

Tokyo Electric Power Company has injected more than 200 cubic meters of nitrogen into the reactor's containment vessel since Thursday evening. But it says the interior air pressure has increased very little.

TEPCO says gas may be leaking from a damaged part of the container.

Also on Friday, TEPCO restarted a system for decontaminating highly radioactive water after a 9-hour stoppage to vent air from a pipe that was slowing down operations.

But it says the system's capability is still more than 20 percent lower than the target figure.

Nitrogen injection and the operation of the water decontamination system are essential for TEPCO to complete the first step of its plan to bring the plant under control.

The utility is still suffering 1 problem after another, with just 2 days left before the first target date of July 17th.

Friday, July 15, 2011 20:14 +0900 (JST)

Radioactive cesium detected in Fukushima shiitake

Radioactive cesium exceeding the government standard has been detected in shiitake mushrooms grown indoors in 2 cities in Fukushima Prefecture, **about 60 kilometers from the troubled Fukushima Daiichi nuclear plant**. This is the first detection of radioactive cesium exceeding the standard in **produce grown in greenhouses** in the prefecture since the nuclear accident.

The Fukushima prefectural government says 1,770 becquerels per kilogram of radioactive cesium was detected in mushrooms grown in Date City. The level is **more than 3 times the provisional government limit of 500 becquerels per kilogram**.

560 becquerels of radioactive cesium was detected in mushrooms from Motomiya City.

At least 157 kilograms of shiitake mushrooms from the 2 cities were shipped from early July through Friday to Tokyo, a supermarket in Fukushima City, and a local farmers' market.

Fukushima officials are to ask the farmers to recall their produce and refrain from making new shipments while determining the cause.

Saturday, July 16, 2011 12:26 +0900 (JST)

Kansai Electric to shut down reactor

Kansai Electric Power Company says it will temporarily shut down a reactor at its nuclear power plant in Fukui Prefecture due to **trouble in an emergency cooling system**. The reactor is one of 19 currently operating in Japan.

Kansai Electric said pressure dropped inside a tank in a system that injects water into a reactor in the event of an emergency at around 11PM on Friday at the **Ohi nuclear plant**.

This made it impossible to inject water properly into the No.1 reactor.

The company said it will manually shut down the reactor to look into the cause of the problem, although pressure returned to normal in about one hour.

The utility plans to suspend the reactor's operation at around 9 PM on Saturday.

It says the trouble caused no leak of radioactive substances to the outside.

Kansai Electric has 11 nuclear reactors, of which 4 are now offline due to regular inspections. 2 more reactors will start undergoing regular inspections next week.

The firm says stoppage of the No.1 reactor would make this summer's limited power situation even tighter.

Kansai Electric says it will try to generate more electricity as well as asking its customers and the public to lower demand for power by around 15 percent.

Saturday, July 16, 2011 14:01 +0900 (JST)

Fukushima reactors 1-3 stabilized

The Japanese government and Tokyo Electric Power Company say they have stabilized the crippled reactors at the Fukushima Daiichi nuclear power plant.

But problems continue with the system for purifying contaminated water.

In a joint assessment, the government and TEPCO say they have completed the first step of a plan outlined in mid-April for a complete cold shutdown of the reactors. They say they completed the first step within the original 3-month deadline.

The assessment adds that reactors 1, 2 and 3 have been stably cooled down, and that nitrogen has been injected into their containment vessels to prevent hydrogen explosions.

Pools of spent nuclear fuel are also stable.

The government and TEPCO say radiation levels in the surrounding air and seawater have been declining, and the goal of reducing the amount of radiation leaking outside the plant has been achieved.

But the crisis is far from over. The assessment admits that contaminated water has leaked out of storage tanks, and that water level settings at its water purification facilities were incorrect.

Saturday, July 16, 2011 08:04 +0900 (JST)

Lawyers join hands to stop nuclear power plants

Lawyers from around Japan are joining hands to take legal action to shutdown nuclear power plants.

Over 50 lawyers from 20 prefectures that host nuclear plants convened in Tokyo on Saturday.

They decided to file a lawsuit to stop the resumption of reactor 1 at the Oi plant in Fukui Prefecture, which is about to be taken offline because of a malfunction. They will also file to prevent the restart of

reactor 1 at the Takahama plant, which is undergoing regular inspections.

The lawyers intend to launch a procedure in autumn to stop the construction of the Oma plant in Aomori Prefecture. The project has been suspended since the March 11th disaster.

Similar lawsuits have been rejected in the past, as courts ruled that safety measures did not present any flaws.

The lawyers argue that the government's current guidelines are seriously compromised, because they do not require plant design to assume an extended interruption of power supply.

Saturday, July 16, 2011 22:17 +0900 (JST)

More beef cattle fed with contaminated hay

Fukushima Prefecture has identified 5 additional farms where straw contaminated with high levels of radioactive cesium was used as cattle feed.

The prefecture says 84 cows that ate contaminated straw were shipped to markets across 5 prefectures, including Tokyo, between late March and mid-July.

The straw was found to contain radioactive cesium up to 379 times above safety standards.

Fukushima Prefecture has conducted on-site inspections at the farms and asked them to stop shipping and transferring cattle on a voluntary basis.

It also ordered local authorities to trace back the meat and recall any products with excessive levels of radioactive contamination.

Fukushima Prefecture launched the inspections earlier this week after it emerged that contaminated straw had been used to feed cattle at one farm.

So far, an investigation has shown that meat from 42 animals raised at the farm was sold to wholesale dealers and supermarkets across 30 prefectures. At least 1,700 kilograms of meat have already been consumed.

Saturday, July 16, 2011 22:18 +0900 (JST)

Gov't to review Fukushima no-entry zone when cold shutdown realized

UKUSHIMA (Kyodo) -- Prime Minister Naoto Kan and Goshi Hosono, state minister in charge of dealing with the nuclear crisis, met Saturday with the leaders of municipalities near the crippled Fukushima No. 1 nuclear power plant and said that the central government will consider reviewing its policy on the no-entry zone near the plant when the reactors at the complex are stabilized.

According to participants, the two said the government will consider reviewing the areas within a 20-km radius of the Fukushima plant, which continues to spew radiation, and also said the government is aiming to bring forward the schedule for stabilizing the reactors from January as previously planned.

Kan's meeting with the leaders of local municipalities came as it appeared almost certain that the Step 1 phase of stably cooling down the nuclear reactors will be achieved on time by Sunday.

The first phase of plant operator Tokyo Electric Power Co.'s time schedule for bringing the troubled nuclear power plant under control includes injecting nitrogen into the No. 3 reactor to prevent a hydrogen explosion.

"To enable a large number of people to go home, we will put all our efforts into realizing Step 2 sooner than planned," Kan said during the meeting with the mayors of Minamisoma, Futaba and other local municipalities at a hotel in Koriyama, Fukushima Prefecture.

The second phase of work to contain the crisis includes achieving a "cold shutdown" of the damaged reactors by January and reducing the amount of water at the plant contaminated with radioactive substances.

The government also plans to consult with the heads of local municipalities to narrow down areas designated for possible evacuation near the nuclear plant, Hosono said.

Hosono said the scaling down of the designated areas should occur after taking necessary steps such as radioactive decontamination, but he did not comment on when the designated areas would be revised.

Hosono told reporters after the meeting that the central government will decide on the timing for narrowing down the areas designated for possible evacuation after confirming their safety and thoroughly consulting with local leaders.

In April, a zone covering nine municipalities within a 20 km radius of the Fukushima plant was designated as off-limits by the government, affecting around 10,500 people. A zone 20 to 30 kilometers from the plant was established in which residents were ordered to prepare for possible evacuation or to remain indoors during an emergency situation. About 58,500 residents are subject to the directive.

Hosono also said that the central government will provide full financial support for the disposal of radioactive waste at the nuclear complex, which has been crippled since the March 11 earthquake and tsunami.

Earlier in the day, Hosono said during a meeting with Fukushima Gov. Yuhei Sato that the government will consider addressing the issue of radioactive waste "on its own responsibility -- without leaving the matter to local municipalities."

Hosono made the remarks in response to Sato's demand that all expenses in connection with the disposal of radioactive waste related to the crisis should be covered by the state coffers.

(Mainichi Japan) July 17, 2011

1st phase of work to contain nuke crisis completed on time: Hosono

TOKYO (Kyodo) -- Goshi Hosono, state minister in charge of handling the nuclear accident, said Sunday that "Step 1" or the first phase of work to bring the crippled Fukushima Daiichi nuclear power plant under control was completed on Sunday as scheduled.

"We believe Step 1 of stably cooling (the reactors) and eliminating risks of a hydrogen explosion has been achieved," Hosono said in a TV program, referring to the road map and time schedule issued April 17 by plant operator Tokyo Electric Power Co.

The utility, known as TEPCO, shares that view. But going forward, concerns linger about whether the country's worst nuclear crisis will be contained as planned as some Step 1 goals were not achieved, including targets for decontaminating radioactive water accumulating at the site.

Under the road map, TEPCO aimed to bring the reactors crippled by the devastating March 11 earthquake and tsunami to a stable condition by Sunday as a first step, and to a "cold shutdown" by next January at the latest as a second step.

TEPCO and the government will announce a new roadmap Tuesday that will highlight the work to be accomplished over the next three to six months, during Step 2 and beyond.

The government-ordered no-entry zone within a 20-kilometer radius of the plant is expected to be reviewed after cold shutdown is achieved under Step 2, government officials said.

During Step 1, TEPCO set up a system to recycle decontaminated water to cool the plant's damaged reactors, while taking measures to cool spent-fuel pools there ahead of schedule.

It also has been injecting nitrogen gas into the Nos. 1-3 reactors to prevent a hydrogen explosion, which could release massive amounts of radioactive substances.

The utility had aimed to process around 1,200 tons of highly radioactive water per day using the new system, but the achievement rate has been only 70 percent so far, company's officials said.

(Mainichi Japan) July 18, 2011

Fukushima water purifying system plagued by failures

July 16, 2011 - <http://ajw.asahi.com/article/0311disaster/fukushima/AJ201107164715>

By NAOYA KON / Staff Writer

Problems stemming from complicated procedures, as well as dumb human errors, have plagued Tokyo Electric Power Co.'s key weapon in ending the crisis at its Fukushima No. 1 nuclear power plant.

In less than a month of operations, the cyclic water injection and cooling system, which purifies accumulated radioactive water and recycles it to cool down fuel rods, has experienced more than 10 suspensions and water leakages.

The system contains 4 kilometers of piping that connects the nuclear reactor buildings, a radioactive water purifying plant and storage tanks. Most of the failures have occurred at the purifying plant.

Water leakages were reported on July 10 and 12 at a purifying unit manufactured by France's Areva SA.

A polyvinyl chloride pipe junction found damaged was replaced by a metal part. But a similar failure occurred at another junction on July 13.

Workers had to fix the problem quickly amid high radiation levels within the site.

A number of failures also hit a unit manufactured by Kurion Inc. of the United States that uses zeolite to absorb and eliminate radioactive substances.

The unit stopped immediately after entering full operations on June 17.

This was the first time for both Areva and Kurion units to be used in such a complicated system to treat saline radioactive water.

Many failures revealed poor preparations.

On June 22, after the performance of Kurion's purifying unit was unusually low, workers found that a valve that should have been closed was actually open in part of the piping. That allowed radioactive water to pass through freely without being purified.

The "open" and "closed" symbols were mixed up near the valve.

On June 29, the equipment stopped and an alarm sounded because a valve that should have been set on "automatic" was erroneously set on "manual."

The following day, Areva's purifying unit stopped automatically because a wrong figure had been set for the water level in a tank.

In the face of these failures, TEPCO has only reiterated: "The system is of an unprecedented large scale. We hope to arrive at stable operations after reviewing the initial glitches."

But the problems do not end there.

Water is still not flowing smoothly within the purifying unit, with the hourly flux only about 70 percent of the original projection.

The cause has not been specified, although TEPCO suspects a flaw in the piping structure.

The water for the entire system is flowing at only 73 percent of capacity. If the utilization rate does not improve, it may compromise TEPCO's goal of removing all accumulated contaminated water in the reactor building basements and elsewhere by the end of this year.

Fukushima Daiichi prepares for typhoon arrival

Tokyo Electric Power Company, or TEPCO, is rushing to put a makeshift roof over a turbine building at the Fukushima Daiichi nuclear power plant as typhoon Ma-on approaches Japan.

TEPCO released a new photo on Sunday showing its preparation work.

The metal roof will cover the turbine building of reactor Number 3. The hole in its roof was caused by a hydrogen blast in March.

The new roof is 5-meters long and 16-meters wide. It is designed to cover up the hole to prevent an increase of radioactive water in the building.

TEPCO says the roof is scheduled to be installed with a crane on Monday.

Fearing high waves, a hose was temporarily disconnected from the "megafloat" barge, which contains relatively low-level radioactive water.

But no measures have been taken to prevent rainwater from entering reactor buildings 1, 3, and 4. The structures were damaged by hydrogen blasts.

However TEPCO says it does not expect any drastic increase of the water level in those 3 buildings.

At the Fukushima Daiichi nuclear power plant the doorway of reactor number 1 was also repaired to prevent rainwater leaks.

Monday, July 18, 2011 05:50 +0900 (JST)

TEPCO covers turbine building as storm approaches

The Tokyo Electric Power Company, or TEPCO, has built a makeshift roof over a turbine building at the Fukushima Daiichi nuclear power plant as typhoon Ma-on approaches.

TEPCO started work to cover a hole in the roof of the No. 3 turbine building on Monday morning. The hole was caused by a hydrogen explosion in a neighboring reactor building in March.

The work ended 6 hours later when the makeshift metallic roof's three parts, each 5 meters long and 16 meters wide, were installed by a crane.

The roof is designed to prevent an increase of radioactive wastewater in the building.

TEPCO plans to cover another hole in the building's roof on Tuesday.

It is also stacking sandbags to prevent rainwater from entering the facility.

Monday, July 18, 2011 23:24 +0900 (JST)

Trouble in water injection at Fukushima Daiichi

Tokyo Electric Power Company, or TEPCO, says it discovered a drop in the amount of water injected into a reactor at the Fukushima Daiichi nuclear plant.

TEPCO says water was moving at a rate of 3.8-cubic-meters per hour to cool down nuclear fuel in reactor number 1 on Sunday morning.

But an alarm warned that the rate had decreased to 3-cubic-meters per hour.

This was third time this month that such trouble had occurred, causing TEPCO to replace the pump in order to stabilize water injection.

Reactor number 2 shares the same pump but has not seen similar trouble. TEPCO says some deposits in the plumbing might have been behind the unstable flow of water.

TEPCO says a decrease in water injection of this level should not trigger a sudden temperature rise in the reactor.

Monday, July 18, 2011 05:50 +0900 (JST)

TEPCO installs cover over No. 3 reactor's turbine building as typhoon approaches

Tokyo Electric Power Co. installs a cover on the No. 3 reactor's turbine building at the Fukushima No. 1 Nuclear Power Plant. (Photo courtesy of TEPCO)

Tokyo Electric Power Co. (TEPCO) carried out repair work on the No. 3 reactor of the Fukushima No. 1 Nuclear Power Plant on July 18 as Typhoon No. 6 approached the nation's Pacific coast.

TEPCO mended one of two holes in the roof of the No. 3 reactor's turbine building by installing a cover over it. The utility was to conduct similar repair work on the other hole on July 19.

The turbine building apparently suffered the damage after a hydrogen explosion rocked the No. 3 reactor building following the March 11 Great East Japan Earthquake and tsunami.

Highly radioactive contaminated water was found in the turbine building, and rain coming through the holes was threatening to raise the water level. The repair work was carried out to prevent the contaminated water from overflowing.

TEPCO installed the cover over the hole, 11 meters long and 14 meters wide, by using three structural objects, each 5 meters long, 16 meters wide and 40 centimeters thick.

During the repair work, radiation doses of two workers were 10 millisieverts above their projected levels, with one of them exposed to a maximum 12 millisieverts.

On July 19, TEPCO will cover the smaller hole measuring 5 meters long and 2 meters wide, along with a roof skylight whose top was destroyed by a blast triggered by the hydrogen explosion.

TEPCO will also use sandbags to cover holes in two gutters whose plumbing had been damaged, company officials said.

Draft accord notes Mongolia as home for spent nuclear fuel

TOKYO (Kyodo) -- A draft Japanese-U.S.-Mongolian agreement over the creation of a nuclear fuel production and spent fuel disposal cycle clearly refers to Mongolia as the destination of such fuel, according to its text, which was obtained by Kyodo News on Monday.

The draft statement of intent among the three countries on the so-called "comprehensive fuel services" would create the world's first framework in which Mongolia exports uranium fuel to other countries and disposes on its soil of the fuel spent there.

The draft agreement mentions the role of the International Atomic Energy Agency, the U.N. nuclear watchdog, in possibly providing technical support to Mongolia in developing used fuel storage facilities there.

While the concept appears difficult to implement in light of the disaster at the Fukushima Daiichi nuclear power plant, hopes for such an initiative linger among those involved, including some private-sector firms.

Establishing a system of permanently disposing of spent fuel that gets generated at nuclear power reactors presents a significant challenge to countries intent on adopting atomic power. Even Japan and the United States, advanced nuclear power users, have yet to establish such a system.

At the same time, Japanese and U.S. companies are eager to capitalize on the initiative as a possible deal-making solution as they go about marketing nuclear power infrastructure to countries interested in adopting nuclear power, critics say.

The draft agreement notes the importance of developing "multilateral approaches" to the nuclear fuel cycle and possibly creating mechanisms for assuring nuclear fuel supply to such countries.

The document also says **the three countries should meet regularly to develop "commercial arrangements to provide comprehensive fuel services at the front-end and back-end of the fuel cycle in a safe, secure, responsible and peaceful manner."**

In Japan, the initiative was led by the Economy, Trade and Industry Ministry. The ministry aimed to have the agreement, drafted by the United States, signed last February, but the move was postponed after the Foreign Ministry lodged an objection, Japanese sources said.

An internal document at the industry ministry's Agency for Natural Resources and Energy, which was created in February and later obtained by Kyodo, noted that **the Japanese ministry and Toshiba Corp. were engaging in behind-the-scenes talks with the U.S. Department of Energy and the Mongolian government over the initiative.**

The document went on to say Mongolia had already begun contacting the United Arab Emirates over the possible supply of Mongolian uranium fuel and acceptance of the fuel after its use.

(Mainichi Japan) July 19, 2011

Anti-nuke groups to fight Manhattan Project parks

ALBUQUERQUE, New Mexico (AP) -- Anti-nuclear activists are lining up against legislation to create national parks at Los Alamos National Laboratory and two other sites where the world's first nuclear bombs were developed, calling the plan an expensive glorification of an ugly chapter in history.

"It is a debasement of the national parks idea," said Greg Mello, a co-founder of the anti-nuclear watchdog, Los Alamos Study Group.

Interior Secretary Ken Salazar released a study to Congress last week that recommends establishing a national historical park to commemorate the top-secret Manhattan Project that developed the atomic bomb. The United States dropped atomic bombs on Hiroshima and Nagasaki, hastening Japan's surrender and ending World War II.

Sen. Jeff Bingaman, a Democrat from New Mexico, said he is drafting legislation to create sites at Los Alamos; Hanford, Washington; and Oak Ridge, Tennessee.

"The secret development of the atomic bomb in multiple locations across the United States is an important story and one of the most transformative events in our nation's history," Salazar said in a release announcing the project. "The Manhattan Project ushered in the atomic age, changed the role of the United States in the world community, and set the stage for the Cold War."

Anti-nuclear activists were appalled.

"Are we really poised to make a national park out of a few shabby ruins where we built instruments of mass murder, delivered to statesmen the instruments of universal destruction, and destroyed the marriage between science and human values?," Mello wrote in an email to board members and others.

"Absolutely disgusting," responded Darwin Bond-Graham in an email. "From a fiscally conservative perspective (which everyone claims these days): surely in this 'time of belt-tightening' the Feds shouldn't waste one cent on crap like this. If the nuclear weaponeers want to do it with all private money, well good for them and their sickened and misguided souls. But not one federal or state cent!"

National Park Service spokesman David Barna defended the idea Monday, noting that there a number of national parks dedicated to significant events in the country's history that are "viewed by some people as not part of our glorious past," including sites of famous Civil War and Native American battles. There are also national parks commemorating tragedies, like the Ford Theater where President Lincoln was assassinated and Pearl Harbor.

Barna said the Park Service would be working to make the sites educational.

The Manhattan Project sites, he said, "are significant parts of our national cultural history. And before they get bulldozed over, we are in favor of preserving these places so future generations can study these events, for good or bad."

(Mainichi Japan) July 19, 2011

Radioactive water in Fukushima poses challenge

The Japanese government and Tokyo Electric Power Company will announce on Tuesday a revised plan to bring the reactors at the Fukushima Daiichi nuclear power plant under control.

They are expected to say that the first stage of the plan has been almost completed on schedule.

But a system to decontaminate radioactive water, which began operating at the end of last month, is working below the target capacity due to leaks and other problems.

The system's decontamination rate dropped to 37 tons of water per hour at one point, more than 20 percent below the target capacity.

It increased to 39 tons per hour after TEPCO workers released air from the pipes on Friday. They also

replaced a hose connecting the tanks to ease water circulation.

However, the rate dropped again to 37 tons per hour on Monday morning. TEPCO says the reason for the decrease is unknown.

Tuesday, July 19, 2011 06:53 +0900 (JST)

Govt to define "cold shutdown"

The second-stage target to bring the nuclear disaster under control will involve achieving a cold shutdown, under which the disabled reactors are to be cooled down to about 100 degrees Celsius or lower.

The Japanese government is due to make this clear on Tuesday when it releases a revised plan to contain the accident at the Fukushima Daiichi nuclear power plant.

The government has so far failed to specify what a cold shutdown entails. It now plans to define the term as bringing reactor-bottom temperatures to about 100 degrees or lower, and substantially reducing the public's radiation exposure by controlling the release of radioactivity.

Achieving a cold shutdown has been cited as one of the conditions for lifting the 20-kilometer no-entry zone around the Fukushima Daiichi plant.

It remains unclear, however, when the lifting would come, as the government still hasn't decided on benchmark levels of radiation that it deems safe enough for people to return to the restricted zone.

Tuesday, July 19, 2011 09:42 +0900 (JST)

Japan to unveil updated roadmap to achieve cold shutdown of reactors

TOKYO (Kyodo) -- Japan is set to release later Tuesday an updated work schedule to achieve a "cold shutdown" of the crippled reactors at the Fukushima Daiichi power plant now that a new water circulation system has stabilized cooling operations and the risk of hydrogen explosions has been eliminated.

Prime Minister Naoto Kan told a parliamentary committee in the morning, "We are starting to see a tremendous critical condition **heading toward a certain level of settlement**," with the completion "almost as scheduled" of the initial phase of Tokyo Electric Power Co.'s timetable to bring the nuclear disaster under control.

Under the timetable initially drawn up by the utility, the cold shutdown is scheduled to be achieved by January at the latest, but Kan said earlier that the government and the plant operator would try their

best to move up the schedule so that people forced to evacuate their homes because of the crisis can return.

Restoration efforts have continued since the March 11 magnitude 9.0 earthquake and tsunami hit the six-reactor complex and led the cooling functions of the reactors and spent nuclear fuel pools at the Nos. 1 to 4 units to fail.

One of the key challenges during the past months has been how to deal with the massive amount of highly radioactive water that has accumulated in the reactor turbine buildings and nearby areas as an outcome of an emergency measure to keep injecting water into the reactors to cool the fuel inside.

Workers have now succeeded in installing devices to remove radioactive substances from the polluted water and recycle the decontaminated water to cool the crippled Nos. 1 to 3 reactors.

Nitrogen, an inert gas, is also being injected into the three reactors to prevent hydrogen explosions from occurring inside the reactors, since such explosions may lead to the release of massive amounts of radioactive substances.

As for the No. 4 unit, where all of its fuel rods had been stored in the spent fuel pool for maintenance work before the disaster struck, work is proceeding to create a system involving a heat exchange device to stably and efficiently cool the water inside the pool.

Kan said that the goals stipulated in the so-called "step one" of the restoration roadmap had been achieved by July 17 almost as scheduled. But not all of the process has gone smoothly.

Most notably, the key water decontamination devices, which started operating in June, have repeatedly faced problems such as water leakage. The system was operating at 73 percent of its capacity by mid-July, lower than the 80 percent target.

During the so-called "step two," which is expected to be implemented in the three to six months following the completion of the first phase, the utility known as TEPCO aims to achieve not only a cold shutdown of the reactors but also a reduction in the total amount of contaminated water in the plant's premises.

TEPCO would also consider creating an underground "shielding wall" to surround the reactor buildings and reactor turbine buildings so as to prevent contaminated water seeping from the buildings and get mixed in with groundwater. The wall is expected to extend 30 meters deep to a layer that does not absorb water.

The utility said in its earlier roadmap that completing the processing of contaminated water is one of the medium-term tasks to be dealt with after the "step two" process ends, but the new roadmap is expected to show that **a maximum period of about three years is to be spent on the medium-term issues**, according to sources close to the matter.

(Mainichi Japan) July 19, 2011

NRC to compile nuclear safety overhaul in 90 days

The top US nuclear chief says his agency will come up with directions on regulatory changes for safety at US nuclear power plants within 90 days.

The chairman of the US Nuclear Regulatory Commission, Gregory Jaczko, says the NRC will quickly evaluate what kind of overhaul is needed at plants, based on the results of a report by its task force.

The NRC ordered a review of safety measures at nuclear power stations around the United States following the accident at the Fukushima plant in Japan.

The task force came up with its **interim report last week**.

The report calls for a reassessment of preparedness for natural disasters such as earthquakes and for each plant to be equipped with enough backup power to keep the facility running in case of blackouts.

In a speech given in Washington DC on Monday, Jaczko stressed that the United States should ensure there is no repetition of what happened in Japan.

In the past, US utilities took more than several years to boost nuclear plant security following an order by the NRC.

The comment by Jaczko suggests that he is determined to speed up the process.

Tuesday, July 19, 2011 11:17 +0900 (JST)

Govt renews Fukushima plant stabilization plan

The Japanese government has announced new stages of a plan to bring the troubled Fukushima Daiichi nuclear power plant under control.

The announcement came at a meeting of the government's nuclear disaster taskforce attended by all Cabinet ministers on Tuesday evening.

The taskforce said the first stage of the plan outlined in mid-April for the stable cooling of the reactors has been completed on schedule by mid-July. It added radiation levels in the plant's surrounding areas have been steadily reduced.

The meeting approved a renewed plan, including the second stage to be completed by next January, and mid-term targets to be achieved within about three years after that.

Under the renewed plan, **the government will carry out regular health checks for about 30 years on residents in Fukushima Prefecture**, where the plant is located. **The checks will include thyroid cancer screening tests for children, the estimate survey of external exposure, and the measurement of internal exposure.**

The government will also start a safety assessment of radiation levels in the evacuation advisory zone around the plant, in an aim to lift the advisories currently in place there.

As for the evacuation zone and the 20-kilometer no-entry zone, the government will start monitoring

radiation levels earlier than planned. The government will start lifting its evacuation orders for areas where safety has been confirmed, after the plan's second stage is achieved by next January.

Also on Tuesday, the government and Tokyo Electric Company formally announced that the target of the first stage to steadily reduce radiation levels from the plant has been achieved, according to a joint assessment.

The assessment said **the radiation level from the turbine buildings of the plant's reactors has been reduced to 1 two-millionth of what it was just after the nuclear accident in March.**

In the second stage of the plan for the cold shutdown of the reactors, TEPCO plans to improve its systems to decontaminate wastewater and to cool reactors and fuel rod pools at the plant.

The government and the utility will have to face tough challenges, as the decontamination system has been developing one problem after another and the plant's reactor buildings have been seriously damaged.

Tuesday, July 19, 2011 20:44 +0900 (JST)

Japan moves on to stage to seek cold shutdown of crippled reactors

TOKYO (Kyodo) -- Japan said Tuesday it has succeeded in stably cooling the crippled nuclear reactors at the Fukushima Daiichi power plant and reducing the radiation dose around the site, an announcement that would lead restoration efforts to move on to the next stage of seeking a "cold shutdown" of the reactors by January.

In an updated road map to contain the four-month-old nuclear crisis, unveiled the same day, the government said it plans to work out by around autumn safety guidelines to maintain the ravaged plant's stability for a long period, while plant operator Tokyo Electric Power Co. will seek to start removing spent nuclear fuel within three years following the stabilization of the reactors.

"We're starting to see a tremendous critical condition heading toward a certain level of settlement," Prime Minister Naoto Kan told a parliamentary committee as he welcomed the completion "almost as scheduled" of the so-called "step one" phase of the utility's restoration road map.

"Some progress has been made earlier than originally scheduled" in the step one phase," Kan also told a meeting of the government's task force on the world's worst nuclear crisis in 25 years.

The government left unchanged the originally set timeline to achieve the "step two" phase, which includes the goal of realizing a cold shutdown of the Nos. 1 to 3 reactors, in the latest scenario.

Industry minister Banri Kaieda said the government could lift a directive that requires residents in a zone 20 to 30 kilometers from the plant to be prepared to evacuate or stay indoors in an emergency, before completing the next phase.

The road map also showed that the government will consider lifting a ban on people entering areas within a 20-kilometer radius of the plant towards the end of the step two phase, which is to be implemented in the three to six months following the completion of the first phase.

As for the definition of a state of cold shutdown, the government said that the bottom part of a reactor's pressure vessel should be basically kept at 100 C or below, and that radiation exposure caused by the additional release of radioactive substances should be "greatly restrained."

At present, the maximum amount of such substances leaking from the damaged Nos. 1 to 3 reactors is 1 billion becquerels per hour, around one two-millionth of the level at the time of the accident, the utility known as TEPCO said.

Based on the data, the maximum radiation dose amounts to 1.7 millisieverts per year around the plant, and TEPCO is expected to bring the level to below the legal limit of 1 millisievert per year, an official at the government's Nuclear and Industrial Safety Agency said.

TEPCO also said it will try to improve the operational ratio of water decontamination devices from around 70 percent of capacity this month as well as consider creating another system as the current water treatment system can be used for only about a year. [Why?]

The utility plans to design an underground wall, expected to extend 30 meters deep, to prevent contaminated water from seeping from the reactor and turbine buildings and getting mixed with groundwater, it said.

Restoration efforts have continued since the March 11 magnitude 9.0 earthquake and tsunami hit the six-reactor complex and led the cooling functions of the reactors and spent nuclear fuel pools at the Nos. 1 to 4 units to fail.

One of the key challenges during the past months has been how to deal with the massive amount of highly radioactive water that has accumulated in the reactor turbine buildings and nearby areas as an outcome of an emergency measure to continue injecting water into the reactors to cool the fuel inside.

Nitrogen, an inert gas, is also being injected into the reactors to prevent hydrogen explosions, which could lead to the release of massive amounts of radioactive substances. But basically all the spent fuel tanks of the Nos. 1 to 4 units are already being kept cool.

(Mainichi Japan) July 19, 2011

Kan defends remarks about nuclear phaseout

TOKYO (Kyodo) -- Prime Minister Naoto Kan defended on Tuesday his comments last week about building a society that does not rely on nuclear energy, as opposition lawmakers grilled him in parliament about what they say was an out-of-the-blue statement about Japan's energy policy.

"What I said at the news conference (on Wednesday) was my basic view" about the direction of the country's energy policy, Kan told a lower house budget committee session, stressing that his comments then were personal and not government policy.

Some ministers had not been informed in advance about the premier's Wednesday remarks, and the apparent lack of Cabinet unity regarding the future of Japan's energy policy has given opposition parties another chance to attack Kan over his handling of the March 11 megaquake and tsunami and ensuing nuclear crisis at the Fukushima Daiichi power plant.

Referring to his choice of words on nuclear energy technology, Kan said that he used those words because he "had doubts about whether this technology could be completely controlled and its safety ensured considering the huge risks."

Kan had said Wednesday Japan should aim to phase out nuclear energy by gradually reducing its use over coming years, and that he felt that the technology of nuclear power generation "cannot be controlled by conventional safety measures."

The prime minister said at Tuesday's Diet session that he would not give a perfect score for his government's handling of the March 11 disaster, but insisted it has done what it can and made some progress in efforts to rebuild the disaster-hit areas and contain the nuclear crisis.

(Mainichi Japan) July 20, 2011

Expert: Risks remain at Fukushima Daiichi plant

An expert says that radiation could be released from the Fukushima Daiichi nuclear plant in about 2 and half days if the injection of cooling water into reactors is halted for any reason.

Masanori Naito, director in charge of nuclear safety analysis at the Institute of Applied Energy, was speaking to NHK about the revised plan to bring the troubled plant under control. The Japanese government and Tokyo Electric Power Company, the plant's operator, announced the plan on Tuesday.

The government and TEPCO said in a joint assessment that the target of the first stage of the original plan ---- to steadily reduce the level of radiation being released from the plant ---- has been met over the past 3 months.

They said the amount of radioactive substances spewing from the No.1 to No.3 reactors has been cut to one 2-millionth of the peak recorded just after the nuclear accident in March.

The effort to stabilize the nuclear facility now shifts to the second stage, when workers will focus on further cutting the release of radioactive substances over the next 6 months. Emphasis will be on reactor cooling systems that recycle contaminated water. The goal is to achieve cold shutdown by reducing reactor water temperatures to below 100 degrees Celsius.

Naito says nuclear fuel levels at the plant have dropped below one-tenth of what they were immediately after the accident, but warns of remaining risks.

He says the government and TEPCO should explain these risks to nearby residents and whether the existing measures will be sufficient.

Wednesday, July 20, 2011 10:26 +0900 (JST)

Cleanup rate at Fukushima plant remains low

A system to decontaminate radioactive water at the crippled Fukushima Daiichi nuclear power plant continues to work below its target capacity.

The plant's operator, Tokyo Electric Power Company, has found that the **system's decontamination rate was about 53 percent during the past week**, compared with the target rate of 70 percent. **It has been unable to reach the target rate for 3 consecutive weeks.**

The utility says the system's low performance rate is due to water leaks as well as the fact that its capacity to remove radioactive materials is 30 percent lower than the catalog states.

TEPCO says the system's performance has not improved even after its piping was changed, and that the cause of the problem is still unknown.

At the troubled plant, water used to cool down reactors has become radioactive and has been accumulating in the basements of the reactor buildings.

TEPCO has operated the cyclical system since late last month, using the water to cool down the reactors after decontaminating it.

On Tuesday, the utility company and the government said that the reactors are being cooled down in a stable manner. However, the system to recycle cooling water is not working well.

At the Number 1 reactor building, the level of polluted water in the basement at 7 AM on Wednesday was 13 centimeters higher than the previous day. TEPCO says a tropical storm has raised the water levels.

A-bomb survivors criticize US tests

Atomic bomb survivors' groups in Hiroshima and Nagasaki have lodged protests against the United States for conducting subcritical nuclear tests.

In Hiroshima, Sunao Tsuboi, head of the Japan Confederation of Atomic and Hydrogen Bomb Sufferers Organizations, said while the tests are not accompanied by nuclear explosions, they are definitely designed to produce lethal weapons.

He added that if the US believes the tests are justifiable, it should announce them forthrightly, but it appears uneasy instead.

He said the group will file a strong protest against the tests, hoping to make slow but steady progress toward the abolition of nuclear weapons.

The head of an atomic bomb survivor's group in Nagasaki, Sumiteru Taniguchi, said that they were betrayed by US President Barack Obama despite their expectations for the president.

He said **the US government appeared to have delayed announcing the tests to avoid criticism and that subcritical tests are in defiance of the international community.**

U.S. Completes Two More Nonexplosive Atomic Tests

Wednesday, July 20, 2011 - http://gsn.nti.org/gsn/nw_20110720_6188.php

The U.S. National Nuclear Security Administration on Tuesday confirmed the United States had completed in the past year two additional nuclear tests that did not involve the fission process necessary for atomic detonations, Kyodo News reported (see [GSN](#), Sept. 17, 2010).

The subcritical tests, conducted on December 1 and February 2, built on last September's "Bacchus" experiment and aided in ensuring the dependability of the U.S. nuclear deterrent, an NNSA representative said. **The September test was the first subcritical trial to have been conducted since August 2006.**

The newly revealed tests were the second and third of President Obama's term, and they **highlighted his administration's commitment to sustaining U.S. strategic offensive capabilities** while other nations also hold nuclear weapons, according to Kyodo. Disclosure of the events could prompt criticism by nuclear weapons opponents, the news service said.

The U.S. Energy Department office publicly cited the two experiments for the first time in a quarterly ["Summary of Experiments Conducted in Support of Stockpile Stewardship"](#) issued in May.

Washington has contended subcritical nuclear tests do not violate the Comprehensive Test Ban Treaty because they produce no atomic detonation (see [GSN](#), July 18). The United States conducted its first such experiment in 1997, following its last nuclear test blast five years earlier (Kyodo News/[Mainichi Daily News](#), July 20).

Subcritical Experiments: High explosive driven experiments to obtain information critical to certifying weapons performance in the

absence of underground testing while still employing nuclear materials. No critical mass is formed due to the amount and quality of the

nuclear material. As such, no self-sustaining nuclear chain reaction can occur in these nuclear experiments. These are therefore not

nuclear explosions. They generally take years to plan, months to execute, and months to analyze. They are all conducted at the NNSS

facilities, usually U1a, to take advantage of containment and entombment.

Decontaminating soil, lowering radiation levels needed to lift evacuation order

A worker from the Japan Atomic Energy Agency measures radiation levels in a sandbox at the Fukushima University-affiliated kindergarten in Fukushima on May 8, 2011. (Mainichi)

In order to lift the evacuation order in areas around the crippled Fukushima No. 1 Nuclear Power Plant, controlling the radiation dosage at low levels and decontaminating soil are the foremost prerequisites.

However, even after the evacuation order is lifted, the affected areas will face a string of problems, including employment and community rebuilding.

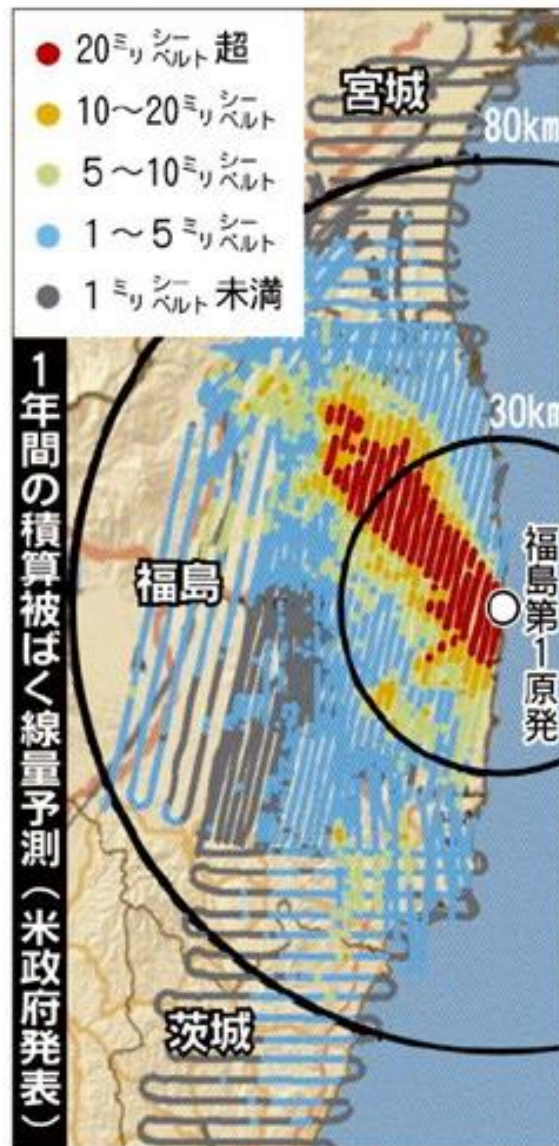

"People won't be able to settle down unless they have jobs. I want authorities to not only lift the evacuation order but to also take every possible measure to bring people back there," said a 50-year-old operator of a retail store in Minamisoma, Fukushima Prefecture.

The city of Minamisoma is part of the 20-kilometer-radius no-go zone as well as the emergency evacuation preparation zone. After the March 11 Great East Japan Earthquake and the ensuing nuclear crisis, the city's key industries of agriculture and fisheries were devastated, while business offices in the manufacturing sector were shut down or downsized.

Four other municipalities in the prefecture that are in the no-go zone and the emergency evacuation preparation zones are also worried about removal of radioactive materials and restoration of housing units that have remained unoccupied by their residents for a long period of time.

"In order to form a community, it will be desirable for residents to return to their hometowns together. I wonder, though, if we can bring people back once they have been scattered, including children who have transferred to other schools," said an official with the Kawauchi Municipal Government -- a village that falls within the 20- to 30-kilometer-radius stay indoors zone.

Another headache for the affected municipalities is disposal of debris and sludge. While the updated timetable for bringing the Fukushima nuclear power plant under control stipulates that collection, temporary storage and disposal of debris and sludge will begin in the Step 2 period, the plan is facing tough challenges as it is difficult to find municipalities that can ultimately accept such waste. Some municipalities are urging that ultimate disposal sites be determined as soon as possible.

The NNSA hazard map released by the U.S. federal government. The Fukushima No. 1 Nuclear Power Plant is marked by a white dot at right.

There is approximately 600,000 tons of debris in Minamisoma, with some 150,000 tons of it collected during the search for missing people and left dumped for more than two months at a planned construction site. The remaining debris is also left piled up in tsunami-ravaged areas.

"No areas will come forward to take such debris," said an official with the Minamisoma Municipal Government's disaster countermeasures headquarters.

Radioactive sludge that is generated at sewage plants is yet another headache. At a sewage plant in the Haramachi district of Minamisoma, the amount of radioactive sludge has topped 80 tons, threatening the facility's capacity. While the return of residents to the area would mean an increase in the amount of sludge, the municipal government has not been able to find a place to temporarily place contaminated sludge.

Despite the government-set standard for the amount of radiation in sludge that can be landfilled, there are cases in which radioactive sludge has nowhere to go due to local residents' opposition. Based on the standard that allows for landfill disposal of sludge whose radiation dosage is under 8,000 becquerels per kilogram, the Fukushima Prefectural Government decided to transfer 1,100-becquerel levels of sludge from a sewage plant in the prefectural town of Kunimi to a final disposal site in the prefecture town of Yanaizu. Although the sludge's radiation dosage was lower than the limit, the town and its residents refused to accept the sludge, saying, "We are concerned about possible health damage that could emerge several years later," leaving the transfer plan up in the air.

"Even if the central government has included disposal of debris and sludge in Step 2, local residents will not necessarily agree to accept contaminated sludge easily. It is a worrisome problem," said an official with the prefectural government's public sewage division.

(Mainichi Japan) July 20, 2011

Over 1,300 cattle suspected of radiation contamination shipped

TOKYO (Kyodo) -- A total of 1,349 cattle suspected of being fed rice straw containing radioactive cesium have been shipped to 45 of Japan's 47 prefectures, a Kyodo News tally showed Wednesday.

On Wednesday, prefectural surveys revealed 699 cattle suspected of such contamination were shipped from farms in Iwate, Akita, Gunma, Niigata, Gifu and Shizuoka prefectures, adding to another herd of such cattle found to have been shipped from farms in Niigata, Fukushima, Yamagata and Saitama prefectures.

In Iwate, up to 57,000 becquerels of radioactive cesium per kilogram -- far above the government-set limit of 300 becquerels -- was detected in rice straw given to cattle at five farms in Ichinoseki and Fujisawa, according to the prefectural government. It was the first time that such cesium has been detected from rice straw produced in the prefecture.

Farms in Shizuoka, Akita, Gunma and Gifu had been feeding their cattle with rice straw produced in the city of Tome, Miyagi Prefecture, bringing the total number of prefectures that have received shipments of Miyagi-produced rice straw to eight.

Radioactive cesium was believed to have emitted from the crippled Fukushima Daiichi nuclear power plant following the March 11 earthquake and tsunami.

While over 1,000 cattle suspected of radioactive contamination were confirmed to have been shipped, less than 10 percent of beef were inspected. The Ministry of Health, Labor and Welfare decided

Wednesday to request municipalities across Japan to put priority on inspecting beef already in the market rather than monitoring vegetables and other products waiting to be shipped.

Farms in Fujinomiya, Shizuoka Prefecture, purchased 70 tons of rice straw produced in Tome. From the straw, 9,380 becquerels of cesium per kg was detected.

In Akita farms, 20,000 becquerels of cesium per kg was detected from straw purchased from a dealer in Tome. A farm in Ota, Gunma Prefecture, purchased about 68 tons of rice straw from a Tome dealer.

In Iwate, where a high level of cesium was detected in rice straws fed to cattle in five farms in Ichinoseki and Fujisawa, it was found that seven other farms in the two municipalities had been feeding cattle with rice straw gathered after the nuclear accident at the Fukushima power plant. But authorities were not able to inspect the rice straw because none was left. From the 12 farms, 81 cattle were shipped.

Miyagi Prefecture has said 64 farms in the prefecture fed their cattle with rice straw gathered after the nuclear accident and that at least 200 cattle had been shipped from 20 farms.

On Wednesday, Iwate Prefecture asked farms not to feed cattle with straw gathered from rice paddies after the nuclear accident and not to ship their cattle fed with the rice straw. Shizuoka Prefecture will also take steps to make sure all farmers are aware that they must not purchase straws suspected of contamination.

(Mainichi Japan) July 21, 2011

U.S. seeks explanation of Japan's energy policy over Kan's remarks

In this June 30, 2011 photo released on July 5, 2011 by Tokyo Electric Power Co., sliding concrete slabs, seen above orange floats, are all set in the upper part of the sluice screen for the Unit 2 reactor at the tsunami-crippled Fukushima No. 1 Nuclear Power Plant in Okuma, Fukushima Prefecture, in TEPCO's effort to decrease the leak of radiation contaminated water to the ocean. (AP Photo/Tokyo Electric Power Co.)

WASHINGTON (Kyodo) -- Japanese State Foreign Secretary Chiaki Takahashi said Wednesday a senior U.S. official called for an explanation about Japan's future energy policy, following Prime Minister Naoto Kan's recent remarks that the country should aim for a nuclear-free society.

After talks with Thomas Nides, deputy secretary of state for management and resources at the State Department, Takahashi told reporters that the U.S. official asked what Japan plans to do in its energy policy in the near term and long term.

Takahashi told Nides that there is no question for Japan to review its basic energy policy following the accident at the Fukushima Daiichi nuclear power plant, but that the country will not move to a society without dependence on nuclear energy right away.

Kan said last week Japan should aim for a society that does not depend on nuclear power in the wake of the nuclear crisis, without specifying a timeline or basic strategy for achieving the goal.

Prior to the meeting, Takahashi also held talks with Deputy U.S. Trade Representative Demetrios Marantis.

In this photo taken on March 31, 2011 by the Japan Maritime Self-Defense Force and released by Japan Defense Ministry on, April 1, JMSDF personnel all in protective suits are aboard a tugboat towing a U.S. military barge carrying pure water towards the quay of the tsunami-stricken Fukushima No. 1 nuclear complex in Okumamachi, Fukushima Prefecture. (AP Photo/Japan Defense Ministry)

The U.S. official urged Japan to join negotiations for a U.S.-led Trans-Pacific Partnership free trade accord at an early date, but Washington understands Japan has delayed its decision on whether to join the talks in the wake of the March 11 disaster.

(Mainichi Japan) July 21, 2011

Contaminated rice straw found in 10 prefectures

The Japanese government says rice straw used for cattle feed contaminated with radioactive cesium has been found in 10 prefectures across the country. Beef produced from cattle fed the contaminated straw and shipped out from farms has already been distributed to almost all prefectures.

Inspectors on Wednesday detected 7 times the government-set maximum standard level of radioactive cesium in rice straw used by a farm in Shizuoka Prefecture. This pushes the number of prefectures

where cattle were fed with contaminated straw to 10.

Most of the rice straw in question was shipped from companies in Miyagi Prefecture, north of Fukushima, where the Fukushima Daiichi nuclear plant, responsible for the contamination, is located.

On Tuesday, the government suspended shipments of beef cattle from Fukushima Prefecture after high levels of radioactive cesium were detected in beef shipped from the prefecture. One beef sample contained radioactive cesium in amounts 9 times the government standard.

Thursday, July 21, 2011 07:31 +0900 (JST)

High levels of radioactivity found extensively

Japan's science ministry says air above the ground about 150 kilometers from the Fukushima Daiichi nuclear plant is as radioactive as areas 50 kilometers from the source of radioactivity.

The ministry on Wednesday released a map showing radiation levels at locations one meter above the ground in Miyagi Prefecture, north of Fukushima, based on the results of an aerial survey from June 22nd through 30th.

Radioactivity levels are highlighted in different colors.

Some parts of Kurihara City, about 150 kilometers north of the plant are light blue, indicating that the air there was 0.2 to 0.5 microsieverts per hour.

That's similar to areas close to the crippled plant, such as Iwaki City in Fukushima Prefecture, about 50 kilometers from the radioactive source.

Radioactive cesium far above the government standard was detected in rice straw for cattle feed collected by a supplier in Kurihara City.

Thursday, July 21, 2011 07:31 +0900 (JST)

Two of 18 active reactors to be shut down

Two of the 18 nuclear reactors now operating in Japan are due to be shut down shortly for regular inspections with no prospect of restarting.

Kansai Electric Power Company says it plans to begin turning off the power of the No.4 reactor at its power plant in Takahama, Fukui Prefecture on Thursday.

The utility also plans to shut down another reactor at Ohi nuclear plant in the same prefecture for regular checkups on Friday.

But the Fukui prefectural government has decided not to approve the resumption of nuclear reactors there until the central government draws up new safety standards for reactors after the nuclear disaster at the Fukushima Daiichi plant.

In Japan, 18 of the country's 54 nuclear reactors are currently in operation.

Thursday, July 21, 2011 07:31 +0900 (JST)

Rain increases contaminated water at plant

Heavy rain brought by a tropical storm has increased the level of radioactive contaminated water at the basements of the crippled Fukushima Daiichi nuclear power plant.

Typhoon Ma-on moved east off the southern coast of Japan's main island of Honshu. 115 millimeters of precipitation was recorded in Namie Town, north of the plant, between Tuesday and Thursday.

Rain has been gathering in the buildings housing the reactors because the roofs were severely damaged by hydrogen explosions that occurred after the initial March 11th disaster.

Tokyo Electric Power Company or TEPCO, the plant's operator, says that at 7 AM local time on Thursday, **the level of contaminated water pooled at the basement of the building of the No. 1 reactor was 44 centimeters up from the previous day.**

Officials at the utility say that there is no immediate danger of the contaminated water spilling out.

But it is likely that the level of water will continue to rise for the time being. TEPCO says they are monitoring the situation.

Thursday, July 21, 2011 16:17 +0900 (JST)

TEPCO: Cooling system operation at Fukushima plant fell to new low recently

The Tokyo Electric Power Co. (TEPCO) has revealed that from July 13 to 19 only 53.7 percent of a water-recycling and reactor cooling system at the Fukushima No. 1 Nuclear Power Plant was running, the lowest percentage since the system began full-scale operations at the end of June.

The system is being used at the No. 1 through 3 reactors to take leaked radioactive water, decontaminate it and send it back in to cool the reactors. Originally the system was predicted to process 50 cubic meters of water an hour, but from July 13 to 19 the system was only processing about 37 cubic meters per hour. TEPCO says the reason is that **water leaks from pipes caused parts of the system to stop.**

TEPCO aims to improve the operational percentage to 70 percent by the end of July and 90 percent in August, but it is not clear that it will be able to meet those goals.

TEPCO also announced that from March to April there were 64 workers engaged in repair work at the Fukushima plant who received internal radiation exposure of 50 to 100 millisieverts.

Meanwhile, press conferences by the joint government-TEPCO disaster task force, which from April 25 had in general been held every day, will from next week only be held once on Mondays and once on Thursdays. Yasuhiro Sonoda of the Cabinet Office explained the reason for the change by saying, "The reactors' conditions have stabilized and there is not a need to give explanations as frequently as there was in the past."

(Mainichi Japan) July 21, 2011

External power supply cut at 2 Fukushima reactors

Tokyo Electric Power Company says part of the external power supply has been cut at the Fukushima Daiichi nuclear plant due to a problem in the transmission lines.

TEPCO said on Friday that a current breaker was tripped by a sudden surge in the external power lines, cutting off electricity to the No. 3 and 4 reactors.

The operator was forced to suspend a system treating radioactive water. Another system cooling the No.3 reactor's spent fuel storage pool was also shut down.

TEPCO says the pool's temperature remains stable at around 30 degrees Celsius.

After the power outage, a building serving as the headquarters for the plant's stabilization switched to an emergency generator.

TEPCO said work to inject water and nitrogen into the reactors has not been affected, as electricity is being supplied from other power sources.

It said radiation levels around the plant show no major change, and claimed there was little risk of a leak occurring.

TEPCO is working to restore external power, as it tries to find out what caused the problem.

Friday, July 22, 2011 11:42 +0900 (JST)

●TEPCO probes Fukushima blackout Earthquake Report JAIF

Tokyo Electric Power Company is investigating the cause of a sudden power failure at the Fukushima Daiichi nuclear plant. The blackout halted the cooling of a spent fuel pool for 5 hours.

The trouble occurred at around 7:10 AM on Friday, when a circuit breaker

malfunctioned on the power feed to the No. 3 and 4 reactors.

The blackout halted equipment to cool the spent fuel pool for the No. 3 reactor.

Cooling was restored around 5 hours later by means of an alternative power source.

The utility says there has been no major change in the pool's temperature of around 30 degrees Celsius.

TEPCO says the incident did not cause any radiation leakage, as work to inject water and nitrogen into the reactors continued with the other power source.

The blackout also halted systems to treat decontaminated water flooding the underground levels of plant buildings, but the company says these were restored at around 3:30 PM.

The company says all facilities disabled by the incident have now been rebooted.

The utility says that although it has installed several external power sources, their automatic switchover functions were not available. The company says it will improve the systems.

A sudden surge in the external power supply is thought to be behind the failure.

TEPCO says it is looking into the problem.

Friday, July 22, 2011 20:23 +0900 (JST)

Prof. Nonaka speaks on cesium in rice straw

A Japanese expert on radiation in soil says radioactive materials on rice straw and soil must be monitored even if they are located far from the troubled Fukushima Daiichi nuclear power plant.

Niigata University Professor Masanori Nonaka spoke about rice straw contaminated with radioactive cesium above the government limit. Contaminated rice straw has been shipped nationwide as cattle feed.

Nonaka said many farmers on the Pacific side of the Tohoku region leave rice straw on paddies to let it dry during winter. He said that was probably how the rice straw, like a sponge, absorbed cesium that had dissolved into rainwater, snow, and soil.

Nonaka said radiation levels in the air were checked after the nuclear accident, but not those in the farmland, produce, and rice straw. He said this is how the rice straw contamination occurred.

Nonaka said to ensure safety radiation in soil and rice straw must be checked, even if they are far away from the nuclear plant.

Friday, July 22, 2011 04:24 +0900 (JST)

Fight over radiation dose limits highlights gov't chaos in early days of nuke crisis

In this March 12, 2011 image made from video from NTV Japan via APTN, smoke rises from Unit 1 of the Fukushima No. 1 Nuclear Power Plant in Okuma, Fukushima Prefecture. (AP Photo/NTV Japan via APTN)

Early in the Fukushima nuclear crisis, as the Self-Defense Forces were flying helicopter water-bombing missions over the overheating reactors, the Prime Minister's Office informed the Defense Ministry that the government would raise the upper radiation exposure limit for nuclear crisis personnel to 500 millisieverts.

The hike in the exposure limit would ultimately be rejected, but the fight over the proposal also highlights the chaos that reigned in government circles as Japan faced one of the most serious crises in the history of nuclear power.

The new policy, delivered on March 17 and titled "Regarding Raising the Upper Radiation Dose Limit," came just three days after the government had raised the exposure limit from the usual 100 millisieverts to 250. The proposed doubling to 500 millisieverts would have brought the emergency upper limit in line with that recommended by the International Commission on Radiological Protection (ICRP).

Hydrogen explosions had ripped through two of the Fukushima No. 1 Nuclear Power Plant's reactor buildings just days before, and working in a radioactive environment was unavoidable if the disaster was to be brought under control.

The 250 millisievert limit was already as high as the Ministry of Health, Labor and Welfare thought it was safe to go. Then prime ministerial aide Goshi Hosono, however, told Akihisa Nagashima, a former parliamentary official for the Defense Ministry, that no real work could be done at that exposure limit,

adding, "We have to get all the government offices in line on this." Nagashima took Hosono's demands verbally to the ministries and agencies concerned.

On March 15, Fukushima plant operator Tokyo Electric Power Co. (TEPCO) pulled all but 50 workers from the crippled power station. An infuriated Prime Minister Naoto Kan contacted TEPCO executives, telling them to become "a suicide unit." Soon after, Kan told people around him that a complete withdrawal from the station would invite direct U.S. intervention to resolve the nuclear crisis.

The response at the Defense Ministry to the March 17 letter from the Prime Minister's Office was ambivalent, with some wondering if it was truly an official demand. With Self-Defense Forces personnel on the front lines of operations to get the Fukushima reactors under control, Defense Minister Toshimi Kitazawa called an emergency meeting on the 500 millisievert exposure limit with senior ministry officials and Self Defense Force chiefs.

In this March 15, 2011 photo released by Tokyo Electric Power Co., smoke rises from the badly damaged Unit 3 reactor, left, next to the Unit 4 reactor covered by an outer wall at the Fukushima No. 1 nuclear complex in Okuma, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

At more than 250 millisieverts of radiation exposure, a person's white blood cell count will dip temporarily. At 500 millisieverts, lymphocyte counts in the bloodstream drop significantly, weakening the immune system. With this in mind, the reaction at the Defense Ministry meeting to doubling the already raised exposure limit was emphatically negative.

"Cancer rates rise at a 500 dose. There's no way we're going through with such a stupid plan," one attendee apparently said, with another pointing out that "raising the limit to 500 just after setting it at 250 will make people wonder what's really safe. On-site personnel won't know what to believe anymore."

Meanwhile, after receiving the policy notification from the Prime Minister's Office, a senior official with the Ministry of Economy, Trade and Industry's Nuclear and Industrial Safety Agency (NISA) told staff to "be prepared to raise the upper exposure limit to 500 millisieverts at any moment." NISA also began coordinating with the Ministry of Education, Culture, Sports, Science and Technology to have the ministerial ordinance governing the radiation limit amended by a radiation commission under the science ministry's jurisdiction.

At just past 6 p.m. on March 17, Kan and Hosono met with Kitazawa, Minister of Health, Labor and Welfare Ritsuo Hosokawa and Minister of Economy, Trade and Industry Banri Kaieda to talk over the exposure limit.

"So, can we raise the limit to 500 millisieverts?" Kan asked the assembled men, to which Kitazawa said, "A hasty jump would not be a good idea."

Under ICRP recommendations, exposure of up to 500 millisieverts should only be risked to save lives in emergencies.

"If down the road a major explosion happens or is possible, then that situation needs to be communicated to the Japanese people," read a message sent to the Prime Minister's Office summarizing the Defense Ministry's position on the exposure limit. "If there is no such risk, then the ministry believes there is no need to raise the radiation dose limit."

This satellite image provided by DigitalGlobe shows the damaged Fukushima Dai-ichi nuclear facility in Japan on Monday, March 14, 2011. Authorities are struggling to prevent the catastrophic release of radiation in the area devastated by a tsunami. (AP Photo/DigitalGlobe)

The Prime Minister's Office denied there was any risk of further explosions at the plant. And thus, in the end, the 500 millisievert limit never became a reality for the workers struggling to tame the Fukushima reactors.

The struggle over the 500 millisievert dose, however, highlights the terrible confusion and disorder within the government during the unprecedented nuclear crisis. In fact, resolving this confusion came to displace the safety of workers on-site as the central concern of the government.

(Mainichi Japan) July 25, 2011

Fukushima to provide lifetime thyroid tests in wake of nuclear crisis

One-year-old Himari, center, held by her mother Tomomi Sato, left, undergoes a radiation screening test at the welfare office in Oyama, Fukushima Prefecture, on May 24, 2011. (Mainichi)

The Fukushima Prefectural Government decided on July 24 to provide lifetime thyroid gland tests for **some 360,000 prefectural residents aged 18 and under** to help detect thyroid cancer triggered by radiation from the crisis-hit Fukushima No. 1 Nuclear Power Plant.

The free tests will be launched in October. Eligible residents will be tested once every two years until the age of 20, and once every five years thereafter. The prefectural government's move is said to be unprecedented.

After the Chernobyl nuclear accident in the former Soviet Union in 1986, residents around the plant who consumed milk and other products contaminated with radioactive materials were exposed to radiation internally, and four to five years after the accident, an increase in infant thyroid cancer cases was confirmed. Thyroid cancer can for the most part be treated if it is detected at an early stage, and the Fukushima Prefectural Government decided that continuous testing was necessary.

The tests are available to people born between April 2, 1992, and April 1 this year who were residents of Fukushima Prefecture at the onset of the nuclear crisis, or who evacuated out of the prefecture in the wake of the crisis. **For the time being residents will be tested at Fukushima Medical University, and later group testing will be carried out at public halls, schools and other locations with assistance from private medical institutions.** The prefectural government hopes to have the first round of testing completed for all eligible residents by March 2014.

The prefectural government has decided to question all 2 million residents of the prefecture on their movements in the wake of the nuclear crisis, and compare the information with measured radiation levels to estimate each person's exposure to radiation. It will start full-scale distribution of questionnaires in August, and will also investigate people's mental wellbeing focusing on residents of evacuated areas.

The central government is considering establishing a fund totaling about 100 billion yen to cover health checks on all prefectural residents, and the thyroid gland checks on people aged 18 or under are expected to be covered by this fund.

(Mainichi Japan) July 25, 2011

Contrary to power company figures, cost of nuclear power generation highest: research

In this photo from a footage of a live camera released by Tokyo Electric Power Co. (TEPCO), black smoke billows from the crippled Fukushima No. 1 Nuclear Power Plant in Okumamachi, northeastern Japan, on March 22, 2011. (AP Photo)

Utility companies across the country continue to tout the low cost of nuclear energy on their websites.

Tohoku Electric Power Co. boasts nuclear power's economic efficiency, while Hokkaido Electric Power Co (HEPCO) the stability of its cost. Each site comes with bar graphs indicating the cost of generating power through various power sources, and the figures are exactly the same regardless of the utility. For every kilowatt-hour of power generated, hydroelectricity is listed as costing 11.9 yen, petroleum 10.7 yen, liquefied natural gas 6.2 yen, coal 5.7 yen, and nuclear 5.3 yen.

In a section of its website responding to questions sent in by elementary school children, Chubu Electric Power Co. informs us that nuclear power "is the cheapest." The media, including the Mainichi, have often cited the information provided to us by power companies.

However, Kenichi Oshima, a professor of environmental economics and policy at Ritsumeikan University, has done some calculations and has reached a completely different conclusion. Oshima says that the cost for a kilowatt-hour of electrical power between fiscal 1970 and fiscal 2007 was 10.68 yen for nuclear, 3.98 yen for hydroelectric, and 9.9 yen for thermal generation, with nuclear-generated power coming out as the most expensive. These calculations were even presented at a meeting of the government's Atomic Energy Commission last September. So how does one explain these two different conclusions?

First of all, there is a huge gap between estimates given by power companies and figures derived from actual records.

The figure "5.3 yen per kilowatt-hour of power" as the cost of nuclear power generation is an estimate submitted in 2003 by the Federation of Electric Power Companies of Japan (FEPC) to a subcommittee of the Committee for Natural Resources and Energy, an advisory body to the Minister of Economy, Trade and Industry. The estimate presupposed a power plant that began operations in the 2002 fiscal year and would run 40 years with a utilization rate of 80 percent. Construction costs were calculated based on an actual power plant that had recently begun operations, and foreign exchange rates and fuel prices needed to calculate the cost of importing fuel were derived from economic indices at the time. It's a government-endorsed figure that has continued to give nuclear-power generation the "low cost" seal of approval.

Oshima's calculations, meanwhile, have been based on actual performance figures found in utilities' corporate financial reports. These reports list various expenditures including labor and fuel costs, as well as depreciation expenses, by power source, which are plugged into a mathematical formula established by the Ministry of Economy, Trade and Industry (METI) and used by power companies to calculate electricity production costs. Dividing source-specific "expenditures" by "actual generated power," we come up with 8.64 yen, 9.8 yen and 3.88 yen per kilowatt-hour for nuclear, thermal, and hydroelectric power, respectively. Already at this point, the figures differ from the estimates.

The top of the No. 1 reactor at Tokyo Electric Power Co.'s stricken Fukushima No. 1 Nuclear Power Plant is pictured in this photograph taken in early May. (Photo courtesy of a power plant worker)

Furthermore, in the calculations, Oshima included funds from the national government -- in the form of subsidies to local municipalities and other financial assistance -- to expenses.

"The public foots the cost of fuel through power bills, but if you trace the financial assistance from the national government back to their source, they're taxes," Oshima says. "My calculations looked at how much of the burden of power generation is resting on the shoulders of the public."

A major pillar of the government's financial assistance comes in the form of subsidies as stipulated in Japan's three power source-related laws. According to Oshima's research, 70 percent of past subsidies given out based on the laws were funneled toward nuclear power projects.

Oshima says that such subsidies, in essence, are all "nuclear power subsidies." This is how he reached the conclusion that every kilowatt-hour of power generated by nuclear power costs 10.68 yen.

"The national government's method of calculating data is valid, but because it is based on the premise that nuclear power plants run at 80 percent capacity, which is higher than the actual rate (70 percent), the final cost comes out as being lower," says Oshima. "The reason the cost of hydroelectricity is so high (in the national government's calculations) may be because the calculations presuppose that hydroelectric plants will operate for 40 years. In fact, many hydroelectric facilities have been in use 60 years or longer, and because their depreciation has ended, costs are kept down. We cannot reach the conclusion that nuclear power generation is inexpensive, at least according to my calculations."

There's also a problem that's specific to nuclear energy. As Oshima points out, massive amounts of money are needed to dispose of spent nuclear fuel, of which there are two options. There is what's called direct disposal, which entails burying the used fuel underground. The other option is to reprocess and reuse the spent fuel in a process known as a nuclear fuel-cycle. Japan's current nuclear policy aspires to the latter by using a fast-breeder reactor to burn spent plutonium and uranium, but such a reactor has not yet reached commercial viability. "Pluthermal" power generation, or the burning of MOX fuel made from a combination of plutonium and uranium in existing reactors is being conducted for the time being.

In 2003, the FEPC submitted an estimate for the total cost of treating nuclear waste to the aforementioned subcommittee of the Committee for Natural Resources and Energy. The amount: 18.8 trillion yen. Of that total, 11 trillion yen was allotted for the actual reprocessing, 2.5 trillion yen to the disposal of highly radioactive waste produced during reprocessing, and 1.1 trillion yen to MOX fuel

processing. The cost of reprocessing is already included in utility bills, but Oshima does not think this will suffice.

"Some expenses, such as that of reprocessing MOX fuel, have been left out," Oshima points out. "Moreover, the costs for the reprocessing plant that was built in the Aomori Prefecture village of Rokkasho are calculated on the assumption that it will run at 100-percent capacity, but looking at cases abroad, such a thing is impossible. Since just half of spent fuel will be reprocessed there, the total cost will actually be twice as much as the 11 trillion yen that has been estimated.

"Will the public be open to such a high-cost project? If we were to funnel funds earmarked for reprocessing and the nuclear budget, it would be very feasible to get power generation with renewable sources of energy off the ground."

Meanwhile, Takeo Kikkawa, a professor of business history at Hitotsubashi University, accepts the legitimacy of Oshima's preliminary calculations, but also points out the importance of assessing whether power is expensive or cheap from the standpoint of corporations and other heavy utility consumers.

"In fact, in Europe, commercial electricity is cheapest in France, a nuclear-power proponent, and the most expensive in Italy, which abandoned nuclear power. METI has estimated that if all the nuclear plants in Japan are stopped, fuel costs will rise by 3 trillion yen in the next fiscal year," says Kikkawa. "The cost of maintaining the nuclear power plants will remain the same, and there will be the additional fuel costs, which will amount to higher electricity bills. If that were to happen, we'd be hearing complaints that the manufacturing industry could no longer exist in Japan."

An artist's drawing of a solar power generation system that the University of Tokyo's endowed chair is planning to build in Saudi Arabia. (Courtesy of the University of Tokyo)

Power companies increased the number of nuclear power plants to make a stable supply of electricity possible. It has done so while harboring many contradictions, however, according to Kikkawa.

"In Japan, private corporations have operated nuclear power plants but they could not have done so without the involvement of the national government. Finding new sites on which to construct plants would have been difficult without the support of government subsidies, and financial assistance from the government is essential in nuclear waste disposal. When you think about the fact that the country's largest utility, Tokyo Electric Power Co., is at risk of going bankrupt due to its responsibility for the (ongoing nuclear) crisis, nuclear power is not something that can be handled by private corporations."

The longer the disaster plays out, the greater the cost of countermeasures and compensation payments will become, leading eventually to an increase in the burdens imposed on the public, whether it be in the form of higher electrical bills or something else.

Kikkawa says that there's already been a transformation in public opinion. "The public by now is leaning toward eliminating our dependence on nuclear power. The point of contention is shifting to the 'how' of abandoning nuclear power."

Workers at Fukushima plant report harsh conditions

Workers involved in the restoration of the areas hit by the March 11 earthquake and tsunami and the troubled Fukushima Daiichi nuclear plant say their working conditions have been harsh.

About 1,500 temporary workers of subcontractors hired by leading construction companies gathered in Tokyo on Sunday to discuss the situation.

A man who took part in the construction of emergency housing in Iwate Prefecture said he had been promised 20,000 yen, or 250 dollars, per day, but received only about one-third of the amount.

He said there were inadequate meals and workers had to sleep together 40 per room.

There were also reports about the conditions for those engaged in treatment of radioactive water and piping construction at the Fukushima plant.

The workers were forced to work without any explanation about the risk of radiation or any measures against heat strokes.

Another worker said he has received only half of the wages he had been promised for building temporary housing in Kesennuma, Miyagi Prefecture. He said he wants the government to do something about the unfair working conditions.

The organizers say these issues have not surfaced before because many workers find it inappropriate to complain when they think about the hardships of people in the disaster-hit areas.

TEPCO tackles trouble with decontamination units

The Tokyo Electric Power Company is trying to figure out why a system to decontaminate radioactive water at the troubled Fukushima Daiichi plant remains unstable.

The system funnels in radioactive water accumulated in the underground facility and reuses it as a reactor coolant after decontaminating radioactive substances.

TEPCO started the operation late last month.

The system sends 3.8 cubic meters of water per hour to each of the No.1 and No.2 reactors.

However, the operation has been unstable for the last 3 days. On Friday, the amount of water injected suddenly decreased to 3.4 cubic meters per hour at No.2 reactor, and then fell to 3.2 cubic meters on Saturday.

At No.1 reactor, water levels decreased to 3.3 cubic meters on Sunday morning.

The utility is examining the pumps each time the amount of water goes down in order to return the system to its previous volume.

On Sunday, the system was halted for 7 hours due to trouble with a device to remove salt from radioactive water. TEPCO restored operation with a back-up mechanism.

The utility says it will closely watch each system and try to track down the causes of the instability.

Monday, July 25, 2011 06:32 +0900 (JST)

Contaminated water on increase at Fukushima plant

Tokyo Electric Power Company is injecting fresh water from a nearby dam to make up for the shortage of water in its system for cooling the reactors at the damaged Fukushima Daiichi nuclear plant.

The system decontaminates radioactive water that has accumulated in the plant and circulates it.

TEPCO halted the process of removing salt from contaminated water after an alarm went off around noon on Sunday due to a problem with the installation of the desalination equipment. It resumed the operation in the evening after installing another device.

The new device is only able to treat half the amount of water. The amount of contaminated water has been increasing since the problem occurred.

TEPCO began using the new circulatory water injection system late last month. Last week, the government and the utility announced the completion of the first stage of the plan to stabilize the cooling of the reactors.

NHK's reporter points out that as a result of Sunday's trouble, the amount of contaminated water is

increasing. He adds that the recycling of cooling water, a key element of bringing the accident under control, cannot be maintained.

TEPCO is investigating the cause of the problem. The utility says the decontamination system as a whole is not operating stably and it needs to improve its reliability.

Monday, July 25, 2011 14:12 +0900 (JST)

Gov. releases radiation forecast system data

Japan's nuclear watchdog has released results of their analysis on how radioactive substances spread after the Fukushima Daiichi nuclear plant accident.

The Nuclear and Industrial Safety Agency released data analyzed by a computer forecasting system designed to track the movement of radioactive substances based on wind and weather.

The System for Prediction of Environmental Emergency Dose Information, or SPEEDI, calculated 6 days' worth of data, from March 12th through 17th.

The results show the amount of radioactive substances in the atmosphere, external exposures and accumulation on the ground.

A map from March 12th, a day after the disaster, shows radioactive substances first flowed towards the southeast and then gradually moved north.

The Agency says it calculated the data based on updated figures obtained from the nuclear reactors through June.

The 600 pages of information are available on the internet.

The Agency will provide all the data to Fukushima Prefecture. It wants to use the information when conducting health research for its residents to estimate their amount of radiation exposure.

The Origin of the Anti-Nuclear Emblem

'We Wanted a Logo that Was Cheerful and Polite'

By SPIEGEL Staff - <http://www.spiegel.de/international/zeitgeist/0,1518,773903,00.html>

Danish activist Anne Lund designed the "Nuclear Power? No Thanks" logo that has become the symbol of the anti-nuclear movement around the world. She spoke with SPIEGEL about how the "Smiling Sun" was born and why she never made any money from her design.

It is the logo that has been seen at countless anti-nuclear demonstrations over the decades and is perhaps the best-known symbol of the anti-nuclear movement. It has been translated into dozens of languages and copied and co-opted for every opposition movement possible.

The logo, which features the slogan "Nuclear Power? No Thanks" around a cheerful sun, was originally designed by the Danish activist Anne Lund in 1975. Within just a few years, the "Smiling Sun," as the logo is known, had been adopted by anti-nuclear movements around the world. Millions of badges and stickers featuring the symbol have been sold. And it is still as popular as ever: It has been ubiquitous at anti-nuclear demonstrations in Germany in recent years.

Lund never made money from her design, having signed over the rights to the Danish anti-nuclear group Organization for Information on Nuclear Power (OOA). The logo is registered as a trademark in the European Union and the United States.

Lund spoke to SPIEGEL about how the symbol was born and the anti-nuclear movement today.

SPIEGEL: You designed the famous "Nuclear Power, No Thanks" logo that has been seen at countless anti-nuclear demonstrations over the decades. You yourself have been fighting against nuclear power for 35 years. Do you now feel vindicated, after the accident at [Fukushima](#) and the decision by the German government to [phase out nuclear power](#)?

Lund: Unfortunately, yes. But Germany now has an opportunity.

SPIEGEL: What is that exactly?

Lund: The Germans are under pressure to develop new forms of energy. In this area, they can take the lead in terms of technology. German industry is well positioned to do so. Sure, (the transition to renewable energy) would be easier if we had changed course 20 or 30 years ago. But back then, opponents of nuclear power were considered crackpots.

SPIEGEL: You were among the first activists.

Lund : We were a small group. We did everything ourselves, even when we had no idea what we were doing.

SPIEGEL: Such as designing logos?

Lund : At the time, a demonstration was planned, but we lacked a symbol. Unfortunately, we did not have a graphic designer or artist in our group, so I took care of it. I sat down at my kitchen table with old wax crayons which I found somewhere and a block of paper.

SPIEGEL: Why did you choose a sun as a symbol?

Lund : Because the sun is above party politics. We did not want a logo that looked scary, but one that was positive, cheerful and above all polite. That's why we chose the slogan "*nej tak*," which is Danish for "no thanks."

SPIEGEL: How many times has the logo been copied?

Lund : About 20 million stickers and badges alone were sold. The text has been translated into some 50 languages. A few days ago, I found the very first orders. They are so touching: 10 units here, 20 there, handwritten orders from some activist group or other. I remember writing back to tell them that it would take a few more weeks until we had printed new buttons and stickers.

SPIEGEL: Did you get rich from it?

Lund : Not a bit! I transferred all the rights for the logo to the Danish anti-nuclear movement.

SPIEGEL: Do you sometimes regret doing that?

Lund : No. It would have seemed wrong to earn money from it. I never wanted to be a graphic artist or designer.

SPIEGEL: Why not?

Lund : Because I have no talent.

Nuclear waste disposal requires millennial planning

2011/07/22 <http://www.asahi.com/english/TKY201107210365.html>

Hirohito Ohno (The Asahi Shimbun)

The late U.S. semiotics researcher Thomas Sebeok (1920-2001) was a professor at Indiana University when he proposed the establishment of an "**atomic priesthood**" in a report he submitted to the U.S. Department of Energy in 1984.

The problem Sebeok was asked by the department to address was this: How do we warn future generations of the extreme danger of highly radioactive nuclear waste buried deep in underground storage sites? Should someone dig up the waste at a later date, unaware of the danger, the consequences would be catastrophic to society. This isn't your garden-variety industrial waste. It is expected to remain toxic for 10,000 years, or 300 generations. That is **a mind-boggling span of time**. Reverse the clock, and the human race was in the Stone Age 10,000 years ago.

Fast-forward to 10 millennia from now, and the **languages** we are using today will likely have been greatly transformed, if not rendered obsolete. There is no guarantee that even pictures will convey their intended meanings. **Signs and symbols** are fully understood only in their contemporary socio-cultural context. What they mean will become increasingly ambiguous with each generational shift.

The atomic priesthood Sebeok proposed would be a self-perpetuating community, which would employ a "folkloric relay system" to keep its message alive for millennia to come.

Japan's "atomic village" of bureaucrats and nuclear experts has been busy spreading its "safety myth," making people believe their argument that nuclear power generation is safe. The mission of the "atomic priesthood," on the other hand, is to perpetuate its "lore of danger." I think a religious organization like the one proposed by Sebeok might be fit for the long-term mission by placing a taboo on the waste burial site.

I once reported on a primary school that had to be relocated to escape the effects of radiation. No, the school wasn't in Fukushima Prefecture. It was in the Paris suburb of Nogent-sur-Marne in France.

A radium extraction plant was built in this commune in the early 20th century, apparently with the support of Pierre and Marie Curie, co-discoverers of radium.

The school in question was built in 1969. About 20 years later, it made news headlines when radiation was detected there. Faculty members, who spent long hours on the premises, were believed to have been exposed to an estimated 14.5 millisieverts of radiation per year. Work was done to remove residual radiation from the premises, but the removal proved to be only partial, and could never fully allay the concerns of parents.

This is not the only example of the "legacy" of France's pioneering radiology research becoming a major headache for the nation. Until the outbreak of World War II, France was mass-producing goods that contained radium, touting them as fruits of its advanced science. The goods ranged from medical equipment to cosmetics, toothpaste, coffee makers, timepieces and even baby clothes.

Today, many of these products are believed to be lying around in old homes, forgotten among common household junk. A French government official in charge of locating such items explained, "They emit only low-level radiation, but if you stay near them for a few hours, you will be irradiated with a dose that easily exceeds the safe annual level."

Yoshihira Doi, 70, an environmental activist in the city of Tottori, noted: "In promoting nuclear energy, little attention is paid to what happens afterwards."

Following the discovery of a uranium ore deposit in the Ningyo-toge pass along the border of Tottori and Okayama prefectures, uranium mining began in 1956. But the low grade of the uranium made the operation unprofitable, and the operators pulled out in the mid-1960s. In 1988, however, radiation was detected in the huge mounds of excavated earth abandoned around the old mine.

The mounds formed low hills, already overgrown with weeds and shrubs, and Doi and a group of local residents launched a petition for their removal. But it was not until 18 years later that the mounds were finally removed

after repeated negotiations and lawsuits with the former Power Reactor and Nuclear Fuel Development Corporation (present-day Japan Atomic Energy Agency) and the prefectures and municipalities concerned.

"Forget, ignore, lose or procrastinate" seems to be the way of radiation management in Japan as well as France. This is with cases that are only a few decades old, not 10,000 years.

Speaking from his experience as an activist, Doi scoffed, "If you think anyone can keep nuclear waste in safe storage, welcome to the world of sci-fi fantasy." Doi pointed out technical challenges as well as problems inherent in society. Over the centuries to come, there will be political upheavals, there may be wars, and almost all companies currently in existence will disappear.

"Then who's left to take responsibility? Even those mounds of dirt (from the uranium mine) took years to clear away," Doi said. "You can imagine just how herculean a task it will be to dispose of all the rubble in the Fukushima No. 1 nuclear power plant and scrap the crippled reactors."

Radiation works to its own time schedule, while we humans muddle through and repeat our mistakes on our time. I can see how increasingly difficult it will get to "synchronize" those two time frames.

In 2009, the Nuclear Regulatory Commission (NRC) of the United States indicated its decision to think not only 10,000 years ahead, but 1 million years ahead, with respect to the estimated radiation level from a permanent high-radiation nuclear waste disposal facility being planned in Nevada. Reverse the clock again, and our planet of 1 million years ago was inhabited by the Pithecanthropus Erectus ape men.

If we can rely on anything to enable us to properly manage radioactive materials, perhaps it is not so much scientific or social progress as our evolution into a species that can build a stable and safe society.

Hirohito Ohno is the Op-Ed Section editor of The Asahi Shimbun.

"Flirting with Catastrophe: Atomic Power in a Destabilized Climate"

[An op-ed by Beyond Nuclear's Kevin Kamps has been published by *Counterpunch*.](#) Prompted by historic floods in Nebraska threatening atomic reactors on the Missouri River, as well as historic wildfires in New Mexico threatening plutonium-contaminated wastes at the Los Alamos nuclear weapons lab, it describes how the location of atomic reactors on seacoasts, rivers, and the Great Lakes makes them vulnerable to worsening severe weather caused by the accelerating climate crisis. Beyond Nuclear has prepared two backgrounders on this issue: ["Far from 'solving global warming,' atomic energy is too risky to operate in a destabilized climate,"](#) and ["Climate chaos and nuclear](#)

[power.](#) Previously, Beyond Nuclear's Paul Gunter also wrote "[Natural Disasters and Safety Risks at Nuclear Power Stations](#)." The vulnerable locations of the 104 operating U.S. atomic reactors are mapped in Beyond Nuclear's pamphlet "[Routine Radioactive Releases from Nuclear Power Plants in the United States: What are the Dangers?](#)"

[A recent op-ed in the New York Times by Heidi Cullen of Climate Central, "Sizzle Factor for a Restless Climate,"](#) reveals that extreme weather such as the current heat wave across most of the United States will become the norm if we don't solve the climate crisis. IEER's [Insurmountable Risks: The Dangers of Using Nuclear Power to Combat Global Climate Change](#), written five years ago by Dr. Brice Smith, debunked the Nuclear Energy Institute's false myth that nuclear power is any kind of solution to the climate crisis.

Adding a one-two punch at *Counterpunch*, Beyond Nuclear board member Karl Grossman also published an article entitled "[What Could Truly End the Space Program: A Nuclear Disaster Overhead](#)" in the same weekend edition.

Greenpeace souligne les failles de l'EPR en cas de panne électrique

LEMONDE.FR avec AFP | 25.07.11 | 13h19 • Mis à jour le 25.07.11 | 13h52

Le site de Flamanville, en France, où un réacteur nucléaire de troisième génération est en cours de construction.AFP/JEAN-PAUL BARBIER

L'organisation écologiste Greenpeace a pointé des failles, lundi 25 juillet, dans la sûreté du futur réacteur nucléaire de troisième génération, l'EPR, en cas de coupure prolongée de l'alimentation

électrique. Une situation qui s'était notamment produite à la centrale de Fukushima, à la suite du séisme et du tsunami du 11 mars.

"Les mesures de sécurité reposent sur l'hypothèse que soit l'électricité fournie par le réseau électrique soit les groupes électrogènes de secours primaires peuvent être rétablis dans un délai de vingt-quatre heures", souligne Greenpeace, qui rappelle qu'"à Fukushima, la panne totale d'électricité a duré onze jours". L'association écologiste s'appuie sur un rapport commandé à Helmut Hirsch, expert autrichien du nucléaire auprès des gouvernements allemand et autrichien, et membre du groupe d'experts de l'Agence de l'énergie nucléaire de l'OCDE.

"AREVA SOUS-ESTIME LE RISQUE"

Selon ce rapport, *"la principale leçon de Fukushima, c'est que les réacteurs sont vulnérables en cas de coupure de l'alimentation électrique des systèmes de secours fondamentaux". Or, selon cet expert, une situation similaire à celle connue au Japon sur un EPR ne permettrait notamment pas de "refroidir l'eau du réacteur en-dessous de 100 °C et de parvenir à un arrêt froid (arrêt stable et sûr) du réacteur".*

"Areva sous-estime le risque de coupure d'électricité (...) au point d'avoir amoindri les mesures de précaution entourant l'EPR" par rapport aux centrales existantes, assure même Greenpeace. Selon l'organisation, "le nombre de groupes électrogènes de secours a été réduit" et ils doivent être "activés manuellement, ce qui augmente le risque d'erreur de la part d'un opérateur".

"L'EPR SERA LE RÉACTEUR LE PLUS SÛR AU MONDE."

Le 16 mars, cinq jours après le séisme et le tsunami qui avaient touché le Japon, Anne Lauvergeon, alors présidente du groupe nucléaire Areva, avait estimé que l'EPR aurait évité les fuites radioactives à Fukushima. *"S'il y avait des EPR à Fukushima, il n'y aurait pas de fuites possibles dans l'environnement, quelle que soit la situation",* avait-elle déclaré à la presse après une audition à l'Assemblée par les parlementaires.

Invité ce matin de la [matinale de France Inter](#), le ministre de l'industrie, Eric Besson, a réagi à ce rapport. Il a notamment remis en cause l'expertise du chercheur autrichien Helmut Hirsch, et le sérieux de l'association écologiste. Il a ainsi estimé que *"Greenpeace a dit tellement de bêtises sur ce sujet depuis tellement longtemps, je ne connais pas le rapport en question, simplement, je vois ce que disent les meilleurs experts internationaux, pas français, ils considèrent que, en l'état actuel des connaissances, l'EPR sera le réacteur le plus sûr au monde".*

La mise en service de l'EPR de Flamanville (Manche), le premier réacteur de troisième génération, n'est plus attendue que pour 2016, avec [deux ans de retard](#) sur la date initiale, a annoncé mercredi dernier EDF.

Eisenhower quelled Japanese fears about nuclear weapons with "atoms for peace"

Eisenhower delivering "Atoms for Peace" speech at UNHow could it be that the only nation ever attacked with nuclear weapons would choose to embrace atomic energy just a decade later? [The Japan Times Online has reported](#), based upon declassified U.S. federal government documents from the Eisenhower administration, that the American promotion of nuclear power in Japan in the mid-1950s was aimed at quelling Japanese fears about, and protests against, U.S. nuclear weapons testing in the Pacific region. The Eisenhower State Department recognized the Japanese outrage about the exposure of Japanese fishermen aboard the Lucky Dragon No. 5, downwind of the Bikini Atoll hydrogen bomb test in 1954, as the most severe strain between the U.S. and Japan since the atomic bombings of Hiroshima and Nagasaki 9 years earlier. President Eisenhower feared Japan's loss from the U.S. camp to the U.S.S.R.'s influence, and his State Dept. secretly recommended "It is important to our relations with Japan that we seek to remove the strong Japanese notion that atomic and nuclear energy is primarily destructive. We should accordingly attempt at an early point to include Japan in bilateral and multilateral actions intended to develop peaceful uses of atomic energy."

Eisenhower had delivered his famous (or is infamous a more appropriate word, given what it has led to?) "Atoms for Peace" speech at the United Nations General Assembly on December 8, 1953 (see photo at left). Dr. Arjun Makhijani and Scott Saleska, in their 1999 book [The Nuclear Power Deception](#), documented that "Atoms for Peace" was a public relations ploy to calm American fears about the nuclear arms race, and justify the expansion of atomic enterprises in the name of societal benefit, when in fact the effort was more geared to U.S. nuclear weapons production, as well as to court foreign governments in the Cold War competition with the Soviets.

"Uncanny Terrain," a documentary about organic farmers facing Japan's nuclear crisis

["Uncanny Terrain"](#) is a documentary in progress, about organic farmers facing Japan's nuclear catastrophe. A Chicago-based, Japanese American film making team will spend up to a year in the radioactively contaminated regions of northeast Japan downwind of the devastated Fukushima Daiichi nuclear power plant, which is still releasing radioactive steam onto the winds nearly five months after the radioactive catastrophe began. Fukushima and neighboring prefectures are famous for their small, family-run, independent organic farms. Husband and wife team Junko Kajino and Ed M. Koziarski

have already captured powerful video testimonies, and are [requesting monetary donations](#) to enable them to continue their work.

July 25, 2011

Govt to buy back cesium-contaminated beef

The Japanese government says it will buy back beef containing unsafe levels of radioactive cesium that has already reached the distribution chain.

Agriculture minister Michihiko Kano announced the step on Tuesday, adding that the contaminated beef will be purchased through a private-sector body.

Kano said the measure is designed to allay consumer concerns over the feeding of cattle with rice straw containing cesium in excess of the government-set limit.

NHK has learned that nearly 2,900 head of cattle allegedly given such feed have been shipped to 46 of Japan's 47 prefectures, excluding Okinawa.

Excessive levels of cesium have been detected in beef in 6 of the prefectures, including Fukushima, where work continues to contain a nuclear plant accident.

Beef with radioactive cesium at levels within the safety limit will not be bought back. But, the government will subsidize the cost of storing it for the time being.

Agriculture minister Kano assured consumers that these measures will ensure that only safe beef reaches market.

The costs of purchasing and storing the beef will be eventually passed on to Tokyo Electric Power Company, the operator of the disabled nuclear plant.

The government will also help livestock farmers affected by restrictions and price declines by offering them 50,000 yen, or about 640 dollars, for each head of cattle that was supposed to be shipped.

Tuesday, July 26, 2011

New decontamination unit to arrive at Fukushima

A new system to decontaminate radioactive water will arrive at the troubled Fukushima Daiichi nuclear power plant on Tuesday. The current system, the key to cooling the reactors, has been plagued with problems.

The new equipment, SARRY, consists of 14 cylindrical tanks containing minerals. It is designed to reduce radioactive substances in water, such as cesium, to less than one millionth.

The first shipment of tanks and parts left a port in Iwaki, Fukushima on Monday.

The existing device at the plant was hit with problems from Sunday to Monday. Its operating rate has been reduced to 53 percent, far below the goal of 90 percent.

The plant's operator Tokyo Electric Power Company plans to use the new system, along with the existing one.

The utility will bring the remaining components to the Fukushima plant in 2 more shipments. It then aims to begin operating the new system around early August.

Tuesday, July 26, 2011

Power companies' generation figures called into question amid push for reactor restarts

As Japan strives to conserve power following the closure of nuclear reactors in the wake of the meltdowns at the Fukushima No. 1 Nuclear Power Plant, **suggestions have arisen that power companies are underestimating their generating capacity.**

Recently one opposition lawmaker questioned whether power companies, which want to restart their nuclear reactors, have been giving low estimates of the nation's power supply. **Prime Minister Naoto Kan, meanwhile, has shown increasing distrust toward the Ministry of Economy, Trade and Industry (METI), and ordered a review of the nation's power supplies.**

According to METI, the generating capacity of thermal power generation and hydroelectric power generation in fiscal 2009 was 192 million kilowatts. In comparison, peak demand during the high-use summer period ranged between 170 million and 180 million kilowatts. In light of these figures, Social Democratic Party leader Mizuho Fukushima has declared that electricity needs can be covered without nuclear power.

Thermal power generation, however, requires regular inspections, and with hydroelectric power, a drop in water supply in the summer means the facilities can't be used to their full potential, according to the Federation of Electric Power Companies of Japan.

Industry minister Banri Kaieda told the House of Councillors Budget Committee on July 25 that Japan can supply "about 157 million kilowatts" of electricity from non-nuclear sources.

At the end of July, about 70 percent of the 57.2 million kilowatts provided by Tokyo Electric Power Co. was produced through thermal generation, while hydroelectric generation accounted for 20 to 25 percent.

The company has pumped-storage facilities that can generate about 9.6 million kilowatts of electricity, but since the nuclear power plants that have supplied the electricity for pumps are down, only about 7 million kilowatts has been included in figures.

Kansai Electric Power Co. had facilities at the end of fiscal 2010 with a generating capacity of 34.88 million kilowatts, but the listed generating capacity for August stands at 29.43 million kilowatts. Only 14.18 million kilowatts of the 16.91 million kilowatt capacity of the firm's thermal plants has been included in figures. A total of 2.4 million kilowatts cannot be produced due to the suspension of facilities due to aging and other reasons, and company president Makoto Yagi says it would take two to three years to restart them.

The generating capacity of Kansai Electric's hydroelectric power facilities, meanwhile, is 8.2 million kilowatts, but based on past figures, the highest amount that can be expected from them is 6.24 million kilowatts. The company's Sakai solar power generation station that will be completed in October with a generating capacity of 10,000 kilowatts can already produce 6,290 kilowatts. However, as generating ability is swayed by the weather and other factors, the company has not included figures from the station in its total.

Document suggests government estimated 1,600 workers exposed to radiation

The Ministry of Economy, Trade and Industry estimated that approximately 1,600 workers partaking in efforts to rein in the disaster at the Fukushima No. 1 Nuclear Power Plant will be exposed to over 50 millisieverts of radiation, according to a document that emerged July 26 after a citizens' group lodged a request for access to government information.

The internal ministry document was released to the public domain in June after the Japan Occupational Safety and Health Resource Center (JOSHRC) requested the public disclosure of government information. The document originating from the ministry said: "Those who in the days ahead will be exposed to over 50 millisieverts of radiation are expected to number around 1,600."

Based on this estimate, the document, created on April 25, expressed concerns that **"it will be difficult to secure the safety of other nuclear power plants unless those who have been exposed to more than 50 millisieverts of radiation continue to engage in radiation work."** The document also noted that workers should be instructed not to be exposed to over 100 millisieverts of radiation in a five-year period.

The law stipulates that the maximum level of radiation exposure that radiation workers are permitted per year in normal times is 50 millisieverts. According to the operator of the stricken power plant, Tokyo Electric Power Co. (TEPCO), as of July 13, six company employees had been exposed to over 250 millisieverts of radiation -- the amount permitted for workers in emergency situations. Meanwhile, a total of 416 workers from both TEPCO and subcontractors working at the plant have been exposed to more than 50 millisieverts.

A representative for the ministry's Nuclear and Industrial Safety Agency (NISA) says that the agency has yet to confirm revelations concerning the document, including whether or not the ministry actually ran calculations to come up with an estimate.

Temple priest stores residents' radioactive dirt

Temple priest Koyu Abe stands by a pile of bags of radioactive soil at Joenji temple in Fukushima. (Mainichi)

FUKUSHIMA -- A temple priest here is storing radioactive dirt from local residents' properties on temple grounds, calling it his duty to help.

Koyu Abe, 47, has accepted around 160 bags of soil, which now sit piled atop a small hill on the grounds of the temple he manages, called Joenji. Due to the ongoing disaster at the Fukushima No.1 Nuclear Power Plant, soil in many areas has been contaminated with radioactive material, but the national and local governments' response has been delayed.

"The people here are threatened, and I cannot leave them without help," says Abe. "Sacrificing oneself and taking on burden is the duty of a priest."

"Up through the Edo Period (1603-1867), temples served roles similar to today's municipal governments," explains Abe.

Abe's dosimeter reads the soil he has taken on at around 8 microsieverts per hour, but he laughs away the danger, saying "the dirt that's brought in has lower radiation levels than the topsoil."

At the end of May, Abe formed a citizens' group that distributes seeds and seedlings of sunflowers, which are said to absorb radioactive material. He is planning to distribute 20 million seeds by April

next year and, after the flowers have grown and absorbed radioactive material, accept them at the temple.

Abe says that when he explained his plans to take on radioactive soil and flowers, local residents did not object. Around 100 volunteers composed of local residents and temple supporters, as well as a local business that Abe has old ties with, are helping with the work.

"Though I am only a single priest, because of relationships of trust with the community I am able to do this much. The fact that the government's response has been so slow shows that their relationship of trust with the people is broken," says Abe.

Abe says that even after the earthquake, people come to the temple from the early morning to share their troubles. "I just want to return everyone's happiness," says Abe.

UN disarmament meeting focuses on nuclear safety

The United Nations opened its 23rd Conference on Disarmament in Matsumoto city, central Japan, on Wednesday morning.

In a keynote speech at the start of the 3-day event, International Atomic Energy Agency chief Yukiya Amano called the accident at the Fukushima Daiichi one of the most serious and complicated crisis human beings have ever faced.

But he said nuclear power generation will continue to be an important option for many countries, and that the use of nuclear energy will increase in the decades to come.

Amano added that the IAEA will play a leading role to ensure nuclear safety.

Japan has hosted the annual disarmament conference since 1989 as the only country to have experienced atomic bomb attacks.

The focus of the event is on united actions toward a nuclear weapons-free world, including issues such as the US-Russian nuclear disarmament treaty and nuclear development in Iran and North Korea. This year, in the wake of the accident at the Fukushima Daiichi nuclear plant, participants are also discussing nuclear safety.

The conference is being attended by about 90 government officials and experts from 24 countries.

Wednesday, July 27, 2011

Nuclear plant workers developed cancer despite lower radiation exposure than legal limit

The late nuclear power plant worker Nobuyuki Shimahashi's radiation exposure monitoring databook indicated "Y" or yes for jobs he could engage in before some of them were corrected to say "N" or no. (Mainichi)

Of 10 nuclear power plant workers who have developed cancer and received workers' compensation in the past, nine had been exposed to less than 100 millisieverts of radiation, it has been learned.

The revelation comes amid reports that a number of workers battling the crisis at the Fukushima No. 1 Nuclear Power Plant were found to have been exposed to more than the emergency limit of 250 millisieverts, which was raised from the previous limit of 100 millisieverts in March.

According to Health, Labor and Welfare Ministry statistics, of the 10 nuclear power plant workers, six had leukemia, two multiple myeloma and another two lymphatic malignancy. Only one had been exposed to 129.8 millisieverts but the remaining nine were less than 100 millisieverts, including one who had been exposed to about 5 millisieverts.

Nobuyuki Shimahashi, a worker at the Hamaoka Nuclear Power Plant, where operations were recently suspended by Chubu Electric Power Co., died of leukemia in 1991 at age 29. His 74-year-old mother Michiko remembers her son dropping from 80 kilograms to 50 kilograms and his gums bleeding.

Shimahashi was in charge of maintaining and checking measuring instruments inside the nuclear power plant as a subcontract employee. He had 50.63 millisieverts of radiation exposure over a period of eight years and 10 months.

His radiation exposure monitoring databook, which was returned to his family six months after his death, showed that more than 30 exposure figures and other listings had been corrected in red ink and stamped with personal seals.

Even after he was diagnosed with leukemia, the databook had a stamp indicating permission for him to engage in a job subject to possible radiation exposure and a false report on his participation in nuclear safety education while he was in reality in hospital.

"The workers at the Fukushima nuclear power plant may be aware that they are risking their lives while doing their jobs. However, the state and electric power companies should also think about their families. If I had heard it was 'dangerous,' I would not have sent Nobuyuki to the nuclear power plant," Michiko Shimahashi said. "The workers who have done nothing wrong should not die. The emergency upper limit should be cut immediately."

Workers' compensation for nuclear power plant workers rarely receives a mention.

Koshiro Ishimaru, 68, leader of a civic group in the Futaba district in Fukushima Prefecture, notes that six workers at the stricken Fukushima nuclear power plant applied for workers' compensation before the nuclear disaster and four received recognition. Only two of the four identified themselves.

"There are many people who are benefiting from the nuclear power plant and do not want other members of this small community to know about compensation," Ishimaru points out.

When it comes to being entitled to workers' compensation due to diseases other than cancer, the hurdle is much higher.

Ryusuke Umeda, a 76-year-old former welder in the city of Fukuoka, worked at the Shimane Nuclear Power Plant run by Chugoku Electric Power Co. in Matsue and the Tsuruga Nuclear Power Plant run by Japan Atomic Power Co. in Tsuruga, Fukui Prefecture, between February and June 1979.

He soon had symptoms such as nose bleeding and later chronic fatigue before having a heart attack in 2000. He suspected nuclear radiation, applied for workers' compensation in 2008 but was rejected.

His radiation exposure stood at 8.6 millisieverts. Umeda says, "Nuclear power plant workers have been used for the benefit of plant operators. If left unchecked, there will be many cases like mine."

The current guidelines for workers' compensation due to radiation exposure only certify leukemia among various types of cancer. In these cases compensation is granted only when an applicant is exposed to more than 5 millisieverts of radiation a year and develops leukemia more than one year after being exposed to nuclear radiation. For other types of cancer, the health ministry's study group decides if applicants are eligible for workers' compensation.

Chubu Electric unable to remove damaged nuclear fuel rod for 17 years

SHIZUOKA (Kyodo) -- Chubu Electric Power Co. revealed Thursday it has been unable to remove a spent fuel rod that was damaged in an accident 17 years ago from its Hamaoka nuclear power plant in Shizuoka Prefecture.

While spent nuclear fuel is normally sent to the reprocessing plant in Rokkasho, Aomori Prefecture or elsewhere, the damaged rod remains inside the fuel pool of the plant's now decommissioned No. 1 reactor, in a special container, it said.

The company said it had asked domestic research organizations and foreign nuclear fuel firms to take it but to no avail, and is still pondering how to get the rod outside in the absence of clear government rules on how to dispose of damaged fuel that requires more delicate handling.

Chubu Electric denied the same day that it had urged employees and workers at the Hamaoka plant to express support for its so-called pluthermal nuclear power generation project in a government-sponsored promotion event in 2007 when it let them know the event would be held in advance.

After Kyushu Electric Power Co. recently became embroiled in a scandal in which it admitted to an attempt to fake public backing in a similar event, the Economy, Trade and Industry ministry has required electric power companies in Japan to see if they have had similar problems and submit results of internal probes by Friday.

The company serving central Japan asked its employees and workers from its contractors to attend a symposium hosted by the ministry in August 2007 for local people to get a better grasp of the pluthermal project planned for the plant, sources close to the matter said Thursday.

Pluthermal power generation uses plutonium-uranium mixed oxide fuel in an existing reactor and is an important pillar of Japan's nuclear program.

Of 524 people who attended the event, 357 expressed support for the project, the sources said.

The Nagoya-based utility, which postponed the project after the Fukushima nuclear crisis erupted in March and then shut down the Hamaoka plant later at the government's request, says it will inform the ministry as soon as it compiles results of an in-house investigation.

Kyushu Electric has admitted a total of 141 people, including 45 of its employees, sent comments to a government-sponsored television program, aired June 26, via e-mail and fax amid a secret campaign to boost support for the company's plan to reactivate its nuclear reactors.

Researchers invent new substance for decontaminating radioactive water

Researchers have developed a new material highly effective in cleaning the radioactive substances strontium and radioiodine out of contaminated water, the National Institute for Materials Science (NIMS) announced on July 27.

The discovery comes as those trying to cleanse vast quantities of radioactive contaminated water at the crisis-stricken Fukushima No.1 Nuclear Power Plant seek to boost the decontamination rate. NIMS and the Japan Atomic Energy Agency will cooperate to put the new material to practical use as soon as possible.

The material is silica with countless holes in it just 2 to 20 nanometers in diameter, each hole coated on their inner walls with a special compound. Depending on the type of material used, it binds to either radioiodine or strontium, taking the radioactive substances out of the water.

According to NIMS, one gram of the silica material can absorb 20 milligrams of radioiodine or 13 milligrams of strontium, or about 65 billion becquerels worth of strontium 90, produced in nuclear reactors.

The materials currently being used for decontamination also tend to filter out chlorine -- similar to iodine -- magnesium and calcium -- similar to strontium. As sea water -- used to cool the Fukushima reactors -- has high concentrations of chlorine and magnesium, much of the cleansing material's capacity is taken up filtering these elements, pushing down the decontamination rate. The new silica-based material, however, does not have this problem, and in the case of radioiodine, can even be reused.

"If factory-made, you can create tons of this material a day, and even at the laboratory level it costs just 60-70 yen per gram to make," says project Chief Engineer Sherif El Safty. "It is extremely effective for decontamination."

(Mainichi Japan) July 28, 2011

Water treatment system running below capacity

A water decontamination system at the Fukushima Daiichi nuclear power plant has been operating below its target capacity, resulting in delays to the firm's timetable of about 2 months.

Tokyo Electric Power Company started running the decontamination system in late June to remove radioactive substances from water pooled in reactor buildings' basements. Treated water is sent back

into the reactors as coolant.

TEPCO says the system operated at 63 percent capacity from June 17th until Tuesday, though it aimed to run it at 70 percent capacity.

The company was planning to decrease the amount of contaminated water to a safe level by early August. But, it now says the timetable is likely to be pushed back until late September.

The failure to reach the target is mainly attributed to the fact the system's working capacity is at about 30 percent below designed levels. The system has also stopped repeatedly due to various operational problems.

TEPCO says problems seen in the early stages of the operation have been solved, and that it will try to increase the system's treatment rate from now.

Households in radioactive hotspots recommended for evacuation begin leaving

An electronic signboard set up in front of the city office in Date, Fukushima Prefecture, displays radiation levels on June 16. (Mainichi)

DATE, Fukushima -- Four households here were given the keys to public housing on July 28, becoming the first to receive government assistance over an evacuation recommendation issued in late June over radioactive "hotspots."

On June 30, 113 households in four districts of the city were recommended to evacuate due to the detection of the hotspots. Of the households, 10 had already evacuated, and 39 others, including the four that began leaving on July 28, are expected to finish evacuating by the end of August. Another 28 who have expressed the desire to evacuate but are hoping to move out of the prefecture or into private housing do not yet know where they'll go.

As the 113 households were given an evacuation recommendation as opposed to an evacuation order like that issued for the exclusion zone around the Fukushima No. 1 Nuclear Power Plant, the decision of whether or not to leave is left to residents. After the June 30 designations the city government surveyed residents' intentions, and the national and city governments have said they will "respect the opinions" of residents who choose not to evacuate and will not pressure them to leave.

As they handed over the keys to the four households, officials said that the city would attempt to decontaminate the areas while the families are gone. The city is also providing support such as free rent at the city-managed housing.

A 37-year-old woman who lives in one of the four evacuating households told the Mainichi, "We were thinking of evacuating on our own if the city didn't find a place for us to go soon, so I'm relieved they did. But it's small and on the third floor, and though my children will come with me, I'm worried about my husband's parents and grandmother, who are staying behind in our home."

There is also controversy over evacuation recommendations being issued to individual households. Yuichi Takahashi, 41, a community representative who submitted a request to the city and national governments that evacuation recommendations be issued by district, says, "I am angry that the city and national governments are ignoring our request and letting the evacuation recommendations become set in stone. Communities will be destroyed."

(Mainichi Japan) July 29, 2011

TEPCO to extract air from troubled reactors

The operator of the Fukushima Daiichi nuclear power plant says it will extract air from troubled reactors at the plant to measure the amount of radioactive substances. The work is part of efforts to curb the amount of radioactivity released into the atmosphere.

Up to around one billion becquerels of radioactive substances are believed to be released every hour from reactors No.1, 2 and 3. It is not known how accurate this figure is because it was worked out by taking readings of the air on the plant's premises.

Tokyo Electric Power Company plans to extract air inside the containment vessels of the reactors through pipes. The extracted air will be analyzed by a device set up on the first floor of the reactor buildings.

The operation is intended to obtain accurate data on what kind of radioactive substances are being released and in what quantity.

The air extraction is expected to begin later on Friday for the No.1 reactor and in early August for the No.2 unit. No plans have been decided for the No.3 reactor due to high radiation levels in part of its building.

TEPCO hopes the findings may also help the company grasp the extent of leakage of nuclear fuels into the containment vessels.

Under the second phase of its plan to stabilize the plant, TEPCO aims to minimize the release of nuclear materials and bring the reactors to a stable state called a cold shutdown over the next 6 months.

Friday, July 29, 2011 09:43 +0900 (JST)

1,500 tons of radioactive sludge cannot be buried

Nearly 50,000 tons of sludge at water treatment facilities has been found to contain radioactive cesium as the result of the accident at the Fukushima Daiichi nuclear power plant. **Over 1,500 tons is so contaminated that it cannot be buried for disposal.**

Water treatment facilities in eastern and northeastern Japan have been discovering sludge containing cesium.

The health ministry says there is 49,250 tons of such sludge in 14 prefectures in eastern and northeastern Japan.

A total of 1,557 tons in 5 prefectures, including Fukushima and Miyagi, was found to contain 8,000 or more becquerels per kilogram. This sludge is too radioactive to be buried for disposal.

The most contaminated sludge, with 89,697 becquerels per kilogram, was discovered at a water treatment facility in Koriyama City, Fukushima.

The ministry says 76 percent of the roughly 50,000 tons of radioactive sludge is being stored at water treatment plants and they have no ways to dispose of most of it.

It says more than 54,000 tons of additional sludge has not been checked for radioactive materials.

The ministry plans to study how to dispose of the radioactive sludge.

Friday, July 29, 2011 04:35 +0900 (JST)

Japan drops promotion of nuclear power from 5-year science plan

The governmental Council for Science and Technology Policy (CSTP) on July 29 dropped plans to expand nuclear power generation from its newest five-year science program.

The program for fiscal 2011-2015, the fourth in a series, calls for new research and development as Japan plots its future energy and nuclear power policies.

The Cabinet was originally scheduled to approve the program in March but was forced to review it due to the March 11 Great East Japan Earthquake and tsunami, as well as the ongoing Fukushima nuclear crisis. The revised program is expected to be adopted by the Cabinet in late August.

The CSTP, chaired by Prime Minister Naoto Kan, has added a section on "the unprecedented crisis in Japan" to the original version to call for scientific examination of the twin natural disasters and particularly the nuclear incident, and carefully and honestly release its findings to the world.

The council also vowed to actively promote scientific and technological innovation for restoration and revival as disaster-stricken regions struggle to get themselves back on their feet.

The program also recommends beefing up the safety of ports, railways and other infrastructure and strengthening disaster-prevention mechanism for public facilities.

Citing fatigue due to prolonged stays at evacuation centers and posttraumatic stress disorder caused by experience of the megaquake and tsunami, the program vowed to step up research leading to health surveys and analysis, diagnosis and treatment.

Besides the March 11 disasters and the nuclear crisis, the CSTP says the five-year program addresses the environment and health, and emphasizes promotion of technological development to solve the country's problems. The council says it will set up a science and technology innovation strategy council to achieve this objective.

The council envisions earmarking more than 4 percent of gross domestic product for public and private sector investment in research and development over the five-year period, with the state allocating 1 percent or about 25 trillion yen.

Although the R&D investment target faced being prioritized below ongoing reconstruction efforts, it was kept in the revised program at the same amount as in the previous five-year program. Approximately 22 trillion yen was spent under the third five-year program.

(Mainichi Japan) July 29, 2011

Wastewater recycling partially halted at Fukushima

A problematic water decontamination system at the Fukushima Daiichi nuclear power plant has forced its operator to stop pumping out radioactive water pooled in the basements of reactor buildings.

The Tokyo Electric Power Company, or TEPCO, said on Friday that **a waste disposal facility where radioactive water is kept before being decontaminated is almost full because of a delay in the decontamination process.**

As a result, TEPCO suspended the transfer of contaminated water to the facility from the plant's No. 2 and 3 reactor buildings.

The utility uses a wastewater system that decontaminates radioactive water and recycles it as coolant for reactors.

But since a June 17th test run of the system, it has been plagued with glitches and its operating rate has remained below the target of 70 percent.

TEPCO says, however, that the radioactive water in the basements is very unlikely to overflow since the system is working, and that the transfer can resume in 2 days.

TEPCO also reported that one of the system's pumps in a device for removing radioactive cesium has stopped working, but that the failure has not affected the system's operating rate.

Friday, July 29, 2011 16:03 +0900 (JST)

Chubu Electric: NISA tried to deceive public forum

Chubu Electric Power Company says the government's nuclear agency asked it to make sure that questions in favor of nuclear power be asked at a government-sponsored symposium in 2007.

In a report submitted to the government on Friday, the utility said the Nuclear and Industrial Safety Agency requested that it gather participants and have local residents pose prearranged questions at the forum held in Shizuoka Prefecture, central Japan.

The utility said it refused NISA's request to arrange the questions, citing difficulties with ensuring compliance. But senior officials of the Hamaoka nuclear power plant sent e-mails to employees and visited affiliate companies in an effort to comply with the request.

An official of Chubu Electric Power Company said on Friday that his firm issued calls to the public to participate in the forum.

He said he doesn't think the act was an outright breach of the law. But he added that it could have led to the misunderstanding that his firm was trying to manipulate public opinion, and he offered apologies.

The revelation comes after Kyushu Electric Power Company came under fire for submitting fake e-mails in support of a restart of idled nuclear reactors in a government-sponsored meeting for local residents in June.

Following the scandal, the industry ministry ordered the 6 Electric Power Companies to conduct an internal investigation of its activities aimed at winning local support for nuclear power.

Friday, July 29, 2011

NISA doesn't remember issuing any such request (conclusion of the video on NHK)

Japan to seek to scale back on nuclear power in new energy strategy

In this photo taken on Thursday, March 31, 2011 by Japan Maritime Self-Defense Force and released by Japan Defense Ministry Friday, April 1, Top parts of explosion-damaged reactors from left, Unit 4, Unit 3, Unit 2 and Unit 1 of the tsunami-stricken Fukushima Dai-ichi nuclear complex are seen with ravaged waterfront facilities in Okumamachi, Fukushima Prefecture, northeastern Japan. (AP Photo/Japan Defense Ministry)

TOKYO (Kyodo) -- The Japanese government decided Friday to draw up a scenario for reducing the country's reliance on nuclear power in its energy strategy to be worked out next year following the nuclear crisis at the Fukushima Daiichi power plant, but recognized the need to use atomic reactors to deal with imminent electricity shortage problems.

The government also unveiled a set of near-term measures to tackle the power crunch that has emerged as a result of the crisis, showing an estimate that the country's power supply capacity could be about 9.2 percent short of peak demand next summer if no reactors are in operation by that time.

Japan is reviewing its earlier policy to promote atomic energy as the nuclear crisis, triggered in the wake of the March 11 earthquake and tsunami, has raised serious doubts among the public about the safety of nuclear reactors.

The government plans to compile a basic policy of its energy strategy by the end of the year, and the strategy itself next year, based on an outline of its energy policy decided Friday. But the outline did not touch on whether Japan should seek to become a society that does not depend on nuclear energy, as stated by Prime Minister Naoto Kan as his "personal view."

"As for the reduction of the ratio of the country's reliance on nuclear power plants, we should decide how we should act by deepening public discussions," a government paper said.

It also said that "nuclear power plants that have been confirmed as safe should be used" in the meantime as power supply and demand are unstable.

In this March 20, 2011 aerial file photo taken by a small unmanned drone and released by Air Photo Service, the crippled Fukushima No. 1 Nuclear Power Plant is seen in Okumamachi, Fukushima prefecture. From top to bottom: Unit 1, Unit 2, Unit 3 and Unit 4. (AP Photo/Air Photo Service)

Kan told a press conference later Friday, "Based on today's decisions, we would further engage in discussions (on energy matters)... The government will push for the reduction of nuclear reliance systematically and in stages."

In addition to fears of power shortages, the government also said there is a risk that the country's electricity generation costs may rise by more than 3 trillion yen if all nuclear power were replaced by thermal power using oil or liquefied natural gas.

To keep the imminent power supply crunch and rise in electricity bills to a minimum, the government said it plans to promote the introduction of energy-efficient products such as light-emitting diodes and to intensively deploy in the next five years "smart meters" that help control electricity consumption.

The spread of smart meters would help achieve more swiftly a "smart grid" next-generation power delivery network, which is also expected to make much greater use of renewable energy sources such as solar and wind, the paper said.

The government also encouraged the separation of electricity generation and transmission to create a competitive environment in the country's electricity businesses.

Before the quake, nuclear power accounted for about 30 percent of the total electricity generated in the country, which has 54 commercial nuclear reactors. But none of the reactors undergoing checkups has been able to restart since the March nuclear crisis, and others now operating will eventually have to be suspended for such checks.

The government also made clear in the paper that it would take thorough safety measures in using atomic power, but prospects are uncertain whether such a stance would lead local governments hosting the atomic power plants to approve the restart of reactors.

An artist's drawing of a solar power generation system that the University of Tokyo's endowed chair is planning to build in Saudi Arabia. (Courtesy of the University of Tokyo)

Japan's basic energy plan endorsed in June 2010 sought to increase the ratio of the country's reliance on nuclear energy to 53 percent by 2030, but Kan said earlier that the government had no choice but to scrap that plan in the wake of the Fukushima crisis.

The envisioned new energy strategy will be considered through three time frames -- short term covering the next three years, the medium term to 2020, and the long term between 2020 and 2030 or between 2020 and 2050.

(Mainichi Japan) July 30, 2011

Full operation of cooling device begins

The operator of the damaged Fukushima Daiichi nuclear plant has begun full operation of a device to cool a spent fuel storage pool.

The pool holds 1,535 fuel rods, the most for any of the plant's reactors. The wall supporting the pool was damaged in a blast on March 15th.

The Tokyo Electric Power Company reinforced the wall with steel pillars and concrete, and installed a cooling device with a heat exchanger to set up a circulatory cooling system.

TEPCO conducted a test-run of the cooling device at the **Number 4 reactor's spent fuel pool** on Sunday morning. It gradually increased the volume of water flowing into the device before shifting to full operation in the afternoon.

TEPCO says the water temperature of the pool remained above 86 degrees Celsius in the morning and it was around 82 to 84 degrees as of 5 PM.

The company plans to lower the water temperature to around 55 degrees within a month to cool the reactor in a stable manner.

TEPCO is already cooling the water in the spent fuel pools at the Number 2 and 3 reactors. It plans to do the same for the Number 1 reactor soon.

Sunday, July 31, 2011

AOÛT 2011

Fukushima residents join antinuclear group's summer campaign

FUKUSHIMA (Kyodo) -- Fukushima residents joined the chorus calling for the elimination of nuclear power as one of Japan's leading antinuclear groups on Sunday kicked off its nationwide summer campaign in the city of Fukushima, located around 50 kilometers from the crisis-hit Fukushima Daiichi power plant.

It was the first time for the Japan Congress Against A- and H-Bombs to start its annual campaign in the city since its founding in 1965, ahead of the anniversaries of the U.S. atomic bombings of Hiroshima and Nagasaki, as it sought to press its case for the scrapping of nuclear power this year.

Koichi Kawano, a Nagasaki atomic-bomb survivor who heads the organizing group, told more than 800 participants at the opening event in a hotel, "We have opposed nuclear weapons and nuclear power plants under the slogan 'Human beings and atomic power cannot coexist.' But we have to admit our responsibility for causing the accident. We failed to make enough efforts to prevent it."

Koshiro Ishimaru from the town of Tomioka, which hosts some of Tokyo Electric Power Co.'s nuclear reactors, said, "There is nothing more irrational, unreasonable than nuclear power plants. It also creates unfairness among the generations."

Ishimaru, who has been active in opposing nuclear plants for over 40 years, also said he is determined to work so that the call for the elimination of nuclear plants reaches people outside Fukushima.

Anton Vdovichenko, a survivor of the 1986 Chernobyl disaster, was among the participants in the meeting calling for solidarity with people affected by the nuclear crisis in Fukushima. Matashichi Oishi, a former crew member of the Japanese trawler Fukuryu Maru No. 5, which was exposed to radiation from a U.S. hydrogen bomb test at Bikini Atoll in 1954, and Eiji Okumura, an atomic-bomb survivor from Nagasaki, also attended the event.

Prior to the ceremony, more than 1,500 people, including those affected by the crisis at the Fukushima plant triggered by the March 11 earthquake and tsunami, mounted an outdoor rally in the city and called for early containment of the accident.

Noriko Matsumoto, 49, mother of two girls from the city of Koriyama in the prefecture, said, "I wouldn't have come here if this disaster had not happened. I didn't even know there were 10 nuclear reactors in the prefecture and I believed that nuclear power was a clean energy source."

"Since the disaster, one of my daughters has had nosebleeds and says her stomach is upset, so I decided to make her stay at my sister's house in Tokyo. We were forced to evacuate on our own, without any compensation. TEPCO is not thinking about us."

Kenta Sato, from the village of Iitate, near the plant, said, "We were exposed to radiation without choice. And the only thing we know now about such radiation is that there is no certainty about its risks to human health."

Hiromasa Yoshida, 45, a teacher from the no-go zone in the town of Namie, said, "My students have suffered psychological shock. They ask me what we can do to improve the situation, but I have no answer even though I have been a teacher for many years."

The group will hold similar events in Hiroshima and Nagasaki in early August to coincide the 66th anniversaries of the U.S. atomic-bombings of the cities.

Niveau record de radiations mesuré à Fukushima

LEMONDE.FR avec AFP | 01.08.11 | 18h43

Un niveau de radiations anormalement élevé a été mesuré, lundi 1^{er} août, entre les bâtiments de deux réacteurs de la centrale nucléaire accidentée de Fukushima, a indiqué la compagnie Tokyo Electric Power (Tepco), exploitante du site mis à mal par le séisme et le tsunami du 11 mars.

Selon Tepco, le niveau de rayonnement atteint au moins 10 sieverts par heure à proximité de débris accumulés entre les réacteurs un et deux de cette centrale endommagée par le violent tremblement de terre et le tsunami qui ont dévasté le nord-est du Japon il y a près de cinq mois.

Le précédent niveau le plus élevé de radiations dans l'enceinte de la centrale Fukushima Dai-Ichi avait été relevé le 3 juin : il était de trois à quatre sieverts par heure à l'intérieur du réacteur numéro un.

TEPCO INCAPABLE D'EXPLIQUER LA HAUSSE

"Nous sommes toujours en train de vérifier la cause de tels niveaux élevés de radioactivité", a expliqué une porte-parole de Tepco.

Le gouvernement et Tepco prévoient toujours de stabiliser la situation à Fukushima en conduisant les réacteurs vers un état dit d'"arrêt à froid" d'ici au mois de janvier. Diverses actions se poursuivent depuis l'accident pour faire progressivement baisser la température du combustible, notamment grâce à la mise en place d'un système de circulation d'eau de refroidissement.

Environ 80 000 personnes, résidant précédemment à moins de 20 kilomètres de la centrale ou dans des localités ayant été particulièrement contaminées, ont été forcées de quitter leur domicile en raison de risques pour la santé.

Time to dismantle dangerous nuclear reactors, scrap nuclear fuel cycle program

The Great East Japan Earthquake and tsunami that occurred five months ago and ensuing nuclear crisis have reminded the public that natural disasters are unpredictable and that an accident at a nuclear power station could cause irreparable damage to extensive areas.

Risks of serious accidents at nuclear power plants cannot be overlooked in quake-prone Japan. We have proposed that an order of priority for shutting down nuclear plants be set based on their danger, and that the number of such power stations be gradually decreased.

To do so, it is necessary to closely assess the risks of each nuclear power plant.

The massive tsunami generated by the March 11 quake triggered a serious crisis at the Fukushima No. 1 Nuclear Power Plant run by Tokyo Electric Power Co. It is necessary to verify how far human factors -- such as the insufficiency of the plant's preparedness for a serious disaster and a delay in the plant operator's initial response to the disaster -- contributed to the nuclear crisis. Still, it must be kept in mind that all nuclear power plants in Japan are at risk of being badly damaged by earthquakes and tsunami.

Chubu Electric Power Co. has shut down its Hamaoka Nuclear Power Plant in Shizuoka Prefecture, as we had called for, at the strong urging of the central government. The utility and the government should further consider dismantling the plant in view of the inability to predict how much damage will be caused by an earthquake in the Tokai region, which is feared to devastate central Japan.

Numerous members of the public are worried about risks involving aging nuclear reactors. The service life of nuclear reactors is not covered by domestic law. Nuclear reactors must be evaluated after 30 years of operation to see if they have passed their service life, but they often continue to be used for another decade or two. The reasons behind such service life extensions are difficulties in finding locations to build new nuclear plants and power suppliers' attempts to lessen their financial burdens.

However, there are serious problems involving such aging nuclear power plants. Newly developed technology can hardly be utilized to solve safety problems involving the design of aging reactors and entire nuclear power plants. The age-related degradation involving buildings housing such complexes is feared to be overlooked.

Fukushima plant's No. 1 to 4 reactors, which had been in operation for 33 to 40 years, are Mark I reactors that U.S.-based General Electric developed in the 1960s. Risks involving Mark I reactors have been pointed out even in the United States.

The ongoing crisis at the Fukushima No. 1 plant may be attributable to its old design. Its key devices were situated in locations where they could be easily hit by tsunami and there were reportedly problems involving the venting of the reactors.

Of the 54 nuclear reactors across the country, 16 have been in operation for between 30 and 39 years and three have been in operation for 40 or more years. Aging reactors, particularly those that have been in use for at least 40 years, should be shut down and dismantled. Furthermore, whether to dismantle those that have been operated for more than 30 years and less than 40 years should be determined after examining whether their condition has deteriorated because of age.

Even keeping the risks of large earthquakes in mind, we have pointed out that it is unrealistic to immediately shut down all existing nuclear power plants.

Still, it is highly questionable to continue the construction of nuclear power plants that are already under way. The construction work should be suspended to assess the risks. The planned construction of new nuclear power plants should be frozen and whether to go ahead with the construction should depend on an overall nuclear power policy that the government will work out.

In conducting assessments of nuclear power plants, risks must not be deliberately underestimated in order to give the green light to their operations. Instead, the government and power suppliers must judge whether to approve operations at such power stations strictly based on the results of their risk assessments.

The ongoing Fukushima nuclear crisis has also uncovered risks involving spent nuclear fuel pools that have no protection barriers. Thorough safety measures must be taken to ensure the safety of such pools.

As the core of its nuclear power policy, Japan has promoted the nuclear fuel cycle program -- in which plutonium is extracted from spent nuclear fuel and used in fast-breeder nuclear reactors.

However, serious doubts have been raised over the feasibility and safety of nuclear fuel cycle systems since long before the Fukushima crisis. Prospects for operations at the nuclear fuel reprocessing plant in Rokkasho, Aomori Prefecture, and the "Monju" prototype fast-breeder nuclear reactor in Tsuruga, Fukui Prefecture -- the two key facilities in the program -- remain unclear because of repeated technical problems.

The reprocessing plant was originally scheduled to be completed in 1997, but its completion has already been postponed 18 times, and costs for its construction have increased nearly three-fold. The Monju reactor was shut down because of a blaze that occurred immediately after the start of its operations. It developed trouble again immediately after the resumption of its operations last year -- 14 1/2 years after the fire. The schedule to put fast-breeder nuclear reactors into commercial use has been delayed whenever a plan is announced. The feasibility of these reactors is highly doubtful.

Last month, the government announced its policy of decreasing Japan's reliance on nuclear power plants for domestic electric power. In view of this new policy, the government should quickly abandon its nuclear fuel cycle program. Funds set aside for the program should rather be used for efforts to bring the Fukushima No. 1 plant under control.

Nuclear fuel spent at nuclear power stations should be disposed of without being reused. Regardless of whether it is reprocessed, it is difficult to find a final disposal site. Still, if the number of nuclear plants decreases, the accumulation of spent fuel will also slow down.

Even if Japan abandons nuclear fuel cycle systems, the amount of plutonium reprocessed both domestically and overseas is estimated to surpass 40 metric tons. Measures to process such a massive volume of plutonium should be worked out at an early date from the viewpoint of nuclear non-proliferation.

Many experts have expressed grave concern that expertise will be lost if Japan decreases its dependence on nuclear power stations and abandons its nuclear fuel cycle program. It is necessary to

develop and secure a certain number of experts if Japan seeks to safely and efficiently dismantle nuclear reactors while continuing to operate a certain number of nuclear power plants for now.

For example, how about setting up a research base in Fukushima to develop technology for ensuring nuclear power safety, dismantling reactors, radiation management and decontaminating radioactive substances, and attracting experts from all over the world to the facility? Knowledge and technology developed there should be fully used on a global scale.

The importance of technology for the safe management of nuclear reactors and dismantling reactors will increase globally. It is the responsibility of Japan that caused the nuclear accident to make effective use of its experience from the crisis.

(Mainichi Japan) August 2, 2011

Safety agency slams TEPCO for lax ID checks on nuclear plant workers

TOKYO (Kyodo) -- The government's Nuclear and Industrial Safety Agency reprimanded Tokyo Electric Power Co. on Monday for failing to conduct adequate identity checks on workers at the Fukushima Daiichi nuclear plant.

The agency found about the lax security as a result of an on-site investigation it conducted on July 7 after the utility was unable to contact more than 180 workers engaged in operations to bring the crippled nuclear plant under control.

The utility only checked photocopies of identification such as drivers' licenses in judging whether workers should be allowed to enter the premises of the plant, breaching the utility's in-house rules to prevent the theft of uranium and plutonium, the agency said in a statement.

The agency also found cases where TEPCO did not individually distribute entry passes to plant workers but handed them to their supervisors, it said.

In this April 18, 2011 photo released Wednesday, April 20, 2011 by Ehime University Medical Department Prof. Takeshi Tanigawa, workers, mostly employees of Tokyo Electric Power Co., engaged in operations at the tsunami-damaged Fukushima Dai-ichi Nuclear Power Plant, take rest inside a gymnasium that serves as their temporary dormitory at Fukushima Dai-ni Nuclear Power Plant in Naraha, 14 kilometers (9 miles) south of the

former plant in Fukushima Prefecture, Japan. (AP Photo/Ehime University Medical Department Prof. Takeshi Tanigawa)

A nuclear safety agency official said the agency, however, decided against revoking TEPCO's license to install and operate nuclear reactors as the inadequate identification checks "do not constitute systematic and deliberate wrongdoing" and were rather a result of situations created by the crisis at the plant.

TEPCO spokesman Junichi Matsumoto told reporters "So far there has been no case of suspicious persons entering the plant's premises."

In late June, TEPCO alerted the nuclear safety agency that it was unable to contact some Fukushima plant workers as it sought to determine workers' internal radiation exposure.

(Mainichi Japan) August 2, 2011

TEPCO to start work by year-end to block radiation water leak to sea

In this June 12, 2011 photo released on July 5, 2011 by Tokyo Electric Power Co., masked workers in protective outfits prepare to drop one of sliding concrete slabs into a slit of the upper part of the sluice screen for Unit 2 reactor at the tsunami-crippled Fukushima Dai-ichi nuclear power plant in Okuma, Fukushima Prefecture, northeastern Japan, in their effort to decrease the leak of radiation contaminated water to the ocean. (AP Photo/Tokyo Electric Power Co.)

TOKYO (Kyodo) -- Tokyo Electric Power Co. said Monday it will start building by the year-end an 800-meter-long shield between the Nos. 1-4 nuclear reactors at its crippled Fukushima Daiichi power plant and the coastal line to prevent radiation-contaminated water from flowing into the sea.

The work to hammer the shield to a depth of 20 meters in the ground is expected to take some two years for completion, the utility said.

The company, known as TEPCO, plans to work out a basic design for the shield by the end of August.

The designing work was part of the "Step 2" or the second phase of work to bring the plant under control, slated for three to six months from mid-July. On July 19, however, TEPCO changed the schedule and decided to move the design work forward.

The company is also considering surrounding the four reactors with the shield in the end.

TEPCO also said radiation doses of as high as 10 sieverts per hour were detected outside the buildings for the Nos. 1 and 2 reactors.

The dosage, which was detected at the bottom of a principal exhaust pipe between the two reactors by three plant workers at about 2:30 p.m., may be larger than the measured amount as it exceeds the capacity of measuring equipment.

TEPCO will inspect causes of the high dosage, making the area off-limits.

U.S. pressing for deal with other countries to build nuclear fuel repository in Mongolia

Momentum has been quickly building behind the scenes for an ambitious and controversial project led by the United States and Japan to build a nuclear fuel repository in Mongolia as Washington is trying to secure a memorandum of understanding (MOU) with other countries concerned by the end of this year.

After the Mainichi reported on the proposal in May, the United Arab Emirates (UAE), which wants to be able to buy nuclear fuel from Mongolia, joined the list of countries pursuing the project, and earlier this month the U.S. Department of Energy sounded out other countries concerned about signing a memorandum of understanding on the program by the end of this year. The project itself is to build a mechanism in which advanced countries force the maintenance of nuclear waste, which takes at least 100,000 years to break down to become harmless, onto developing countries.

On May 6, 2009, three men landed at Chinggis Khaan International Airport in the Mongolian capital of Ulan Bator. Two men from an American think-tank and a bureaucrat from the Japanese Economy, Trade and Industry Ministry held talks with then-Mongolian Foreign Minister Sukhbaataryn Batbold (currently the prime minister) and Defense Minister Luvsanvandan Bold, telling them, "Mongolia should become the Switzerland of the East." They then presented a proposal written in English on a spent nuclear fuel repository.

Mongolia, sandwiched between China in the south and Russia in the north, has long suffered from repeated interference by the two giants. Drawing on Switzerland, which declared itself a permanent neutral country and boosted its security by hosting United Nations organizations, the three men tried to persuade the Mongolian officials by saying, "If your country builds a storage facility for spent nuclear fuel and has it managed by an international organization, China and Russia will no longer be able to

meddle carelessly in your affairs. In doing so, your country will be able to contribute to the strengthening of security in Northeast Asia."

The proposal is to build a nuclear fuel production facility, nuclear reactors, a research lab and a storage facility for spent nuclear fuel in an area near uranium mines in the Gobi Desert, southern Mongolia, and let the International Atomic Energy Agency (IAEA) manage the facilities.

Their explanations to the Mongolian side focused on security for Mongolia. The Obama administration withdrew its plan late in 2009 to build a storage facility for spent nuclear fuel in an area near Yucca Mountain in Nevada due to strong resistance from local residents. Playing key roles in thrashing out the Mongolian plan were the U.S. Energy Department, which now found itself on a search for an alternative repository site abroad, and Toshiba Corp (including its subsidiary Westinghouse Electric Co.) -- the biggest nuclear reactor manufacturer in both the U.S. and Japan -- which predicts that securing a storage facility for spent nuclear fuel would boost its sales of nuclear power plants overseas.

According to the IAEA, an estimated 330,000 metric tons of spent nuclear fuel exist in the world. About 15,000 tons of such fuel is produced annually and 8,500 tons of such fuel is stored for disposal and 2,000 tons is reprocessed. Even if spent nuclear fuel is reprocessed, it will generate high levels of radioactive substances, and therefore it will need to be contained for the same length of time as that for spent nuclear fuel that is being disposed.

It is extremely difficult to build a nuclear waste repository in the United States and Japan due to fierce opposition from local residents. Therefore, Mongolia, which boasts the lowest population density among U.N. members and sits on solid ground, was singled out for the ambitious and contentious nuclear project.

(Mainichi Japan) August 1, 2011

Highly radioactive water flows into another place

Highly radioactive water has been found in the basement of a building at the Fukushima Daiichi nuclear power plant near the storage facility for contaminated water.

Tokyo Electric Power Company said on Monday that it discovered about 700 tons of contaminated water on Saturday in the basement of an on-site building.

The utility said the water contained 19,000 becquerels of radioactive cesium 134 per cubic centimeter, and 22,000 becquerels of cesium 137 --- both very high levels.

Until June, the building was connected by a hose with another building where highly radioactive water is now being stored. The buildings are located next to each other and are part of the plant's waste disposal facility.

The utility is investigating how the leak happened. But it says it that there is no danger of the contaminated water leaking out of the building.

Monday, August 01, 2011 21:00 +0900 (JST)

Highest radioactivity level detected at nuke plant

The operator of the Fukushima Daiichi nuclear power plant says it has detected 10,000 millisieverts of radioactivity per hour at the plant. The level is the highest detected there since the nuclear accident in March.

Workers of Tokyo Electric Power Company, or TEPCO, on Monday measured the extremely high level of radioactivity near pipes at the bottom of a duct between the No.1 and neighboring No.2 reactor buildings.

According to the science ministry's brochure, if a human received 10,000 millisieverts, they would likely die within a week or two.

TEPCO has restricted access to the site and the surrounding area.

The utility says the workers taking measurements on Monday were exposed to up to 4 millisieverts.

The utility says the high level of radioactivity was detected because the pipes were used to vent air containing radioactive substances from the crippled No.1 reactor on March 12th.

The utility had detected a maximum of 1,000 millisieverts per hour outdoors in debris, and also found a maximum of 4,000 millisieverts per hour indoors in one of the reactor buildings.

Tuesday, August 02, 2011 06:33 +0900 (JST)

TEPCO to check plant radiation levels carefully

The operator of the crippled Fukushima nuclear complex is searching for radioactive hotspots after finding record high radiation near an exhaust pipe at the plant.

Tokyo Electric Power said on Monday that over 10,000 millisieverts per hour had been detected at the bottom of the exhaust pipe in between reactor buildings No.1 and No.2. That's the highest level detected since March when the quake and tsunami disabled the plant.

A photo released on Tuesday shows workers taking measurements with a detector attached to the tip of a 3-meter-long arm. The level of radiation where the workers stood reportedly reached 40 millisieverts per hour.

TEPCO says the exhaust pipe was used when radioactive air was vented from the No.1 reactor's containment vessel one day after the March 11th disaster.

The company subsequently revealed that the reactor had suffered a nuclear fuel meltdown. The utility believes highly radioactive substances that leaked from the container flowed into the pipe and accumulated inside.

The utility has declared the area off-limits, and is planning to seal it off with mats stuffed with lead. It will also carefully check whether there are other highly contaminated sites within the premises that may hamper cleanup work.

Tuesday, August 02, 2011 12:34 +0900 (JST)

No-entry decontamination to start next month

Japan's minister in charge of the nuclear crisis says full-scale decontamination measures will begin next month for the 20-kilometer evacuation zone around the Fukushima Daiichi nuclear plant.

Goshi Hosono made the remark on a commercial TV channel on Monday.

Hosono said the government will begin decontamination on a large scale and continue monitoring radiation levels. He said the government is aiming for a complete cleanup of the evacuation zone.

The minister added that radioactive materials must be removed from the zone so that residents can return home by early next year. January will mark the end of the second stage of a plan to achieve a cold shutdown of the damaged nuclear reactors.

Tuesday, August 02, 2011 06:33 +0900 (JST)

2 TEPCO workers died in tsunami after following orders to check nuclear plant damage

In this March 11, 2011 photo released Monday, April 11, 2011 by Tokyo Electric Power Co.,(TEPCO), the access road at the compound of the Fukushima Dai-ichi nuclear power plant is flooded as tsunami hit the facility

following a massive earthquake in Okuma town, Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.,)

Two Tokyo Electric Power Co. (TEPCO) workers whose bodies were found at the Fukushima No. 1 Nuclear Power plant some three weeks after the March 11 Great East Japan Earthquake and tsunami were struck by the tsunami while inspecting an underground facility under orders, the Mainichi has learned.

The deceased pair, Kazuhiko Kokubo, 24, and Yoshiki Terashima, 21, were ordered by their shift supervisor to check for leaks in the basement of the plant's No. 4 reactor turbine building when they were hit by the tsunami. At the time a major tsunami warning was in place. It is the first time that details on the background to their deaths have emerged.

In an accident report released in June, TEPCO said that the safety of workers had been confirmed after the quake, and that workers were aware of the earthquake and tsunami, but the latest finding suggests that not all workers knew about the impending tsunami.

At the time of the earthquake, the No. 4 reactor was under inspection, and the fuel rods had been removed. TEPCO officials and other sources said that the two workers were in the central control room at the time, inspecting the power operations of the No. 4 reactor and the opening and closing of valves. After the earthquake struck, an alarm went off, indicating that the water level in the cooling tank of the No. 4 reactor turbine building had dropped. The shift manager accordingly ordered the workers to go and check for leaks. Electricity to the building had been cut, so the pair headed to the underground location of the tank pipes with flashlights.

Terashima phoned his parents' home in Mutsu, Aomori Prefecture, at about 3 p.m., and it is believed that he went to inspect the pipes after this.

Japan's Meteorological Agency released a major tsunami warning for Fukushima Prefecture and other areas at 2:49 p.m. on March 11, three minutes after the magnitude 9.0 earthquake struck. The first wave of the tsunami, measuring about four meters in height, hit the Fukushima No. 1 Nuclear Power Plant at around 3:27 p.m. Eight minutes later, a second wave believed to be more than 10 meters high arrived, surging over a coastal levee and practically submerging all of the buildings at the plant.

On March 12, TEPCO announced that two workers were missing. The company later conducted a search in the basement of the turbine building, but high radiation levels in water hampered its efforts. Police found the bodies of the pair on March 30, after the water subsided, and an announcement on the discovery of their bodies was made on April 3.

In this March 11, 2011 file photo released by Tokyo Electric Power Co., waves of tsunami come toward tanks of heavy oil for the Unit 5 of the Fukushima Dai-ichi nuclear complex in Okuma, Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

In a news conference the same day TEPCO said it was "investigating" why the workers went into the turbine building, not mentioning that they had been ordered to conduct inspections.

In a report on the company's response to the accident, which was released June 18 under the title "Response at Fukushima No. 1 Nuclear Power Plant," TEPCO stated that the safety of workers was confirmed and that a paging system was used to inform workers about the earthquake and tsunami. However, it made no mention of the inspection orders issued to the two workers.

A TEPCO representative admitted that the shift manager had ordered the two workers to conduct inspections. The representative said the workers in the central control room were aware of the major tsunami warning but the company was unable to confirm whether the information had reached the two workers.

(Mainichi Japan) August 2, 2011

Nuclear energy can be replaced with renewable energy

The elimination of nuclear power plants cannot be achieved over a short period of time. Therefore, we basically support the government's intention to consider the matter from short-, medium- and long-term perspectives. It is necessary to set a clear timeline if the government is to draw a realistic roadmap toward the goal.

In the short run, there is no choice but to switch to thermal power generation using natural gas. The government should promptly initiate its work to do so because it normally takes about a decade to complete a thermal power station, considering the time required to select and procure a site for the facility.

Circumstances surrounding natural gas have drastically changed. The amount of natural gas produced has sharply increased since the technology of extracting gas from shale was established in the United States. Shale gas fields are being developed in China and many other countries in the world. The

International Energy Agency estimates that the amount of gas consumed on a global scale will increase by 50 percent by 2030. The natural gas age has arrived.

Germany, which has decided to pursue a society without nuclear power, intends to make up for a shortage of electric power with that generated by thermal power stations. However, the price of natural gas will certainly rise because its demand is expected to sharply expand. Measures should be taken on a global scale to not only guarantee contracts to purchase gas but also to expand interest in gas field exploitation.

Of thermal power plants using fossil fuels, those powered by coal emit the largest amount of carbon dioxide, a type of greenhouse gas. However, coal can be stably procured from all over the world, and its price is relatively low. Electric power generated by such plants accounts for approximately 25 percent of electricity consumed in Japan. To ensure a stable supply of electricity, Japan will need to maintain its coal-powered thermal electric power plants. Germany relies on coal-powered electric power plants for 41 percent of electricity consumed domestically, far above the ratio in Japan.

In short, there is no choice but to make up for a shortage of electric power as a result of decreasing nuclear power plants with power generated by thermal power stations until the ratio of power generated by renewable energy sources rises significantly.

However, there are problems involving such efforts including a rise in the costs of generating electric power and an increase in greenhouse gas emissions.

According to an estimate made by the Institute of Energy Economics, Japan, if all domestic nuclear power plants are shut down, the cost of Japan's imports of fuel will increase by 3.473 trillion yen next fiscal year, increasing the monthly average electricity charge by 1,049 yen per household and by 36 percent for businesses.

Business leaders have expressed grave concern that if a shortage of electric power becomes chronic and electric power rate rises as a result, it will force businesses to shift their factories abroad, speeding up the hollowing out of Japan's industry. Some view the shortage of electric power as a unique opportunity to transform Japan's economy, which consumes a massive amount of electric power, into one that relies less on energy. However, adverse changes in the economy, such as a sharp rise in the unemployment rate, must be avoided by all means.

The hollowing out of domestic industry is very complex and it cannot be attributed solely to a rise in energy expenses. Behind the problem are also various factors such as the sharp appreciation of the yen, inadequate infrastructure for manufacturing, a shortage of human resources that have received advanced education, high corporate tax rates and a lack of leadership ability on the part of the government, which cannot decide whether Japan should participate in the Trans-Pacific Partnership Agreement. The government needs to clarify its stance toward supporting businesses and implement specific measures to that end.

If Japan's reliance on nuclear power plants declines, it will be difficult for the government to achieve its goal of reducing greenhouse gas emissions by 25 percent from 1990s levels. Therefore, it should review its goal.

After the Kyoto Protocol on greenhouse gas emission expires, a new system should be created under which Japan's exports of devices that help reduce greenhouse emissions to developing countries can be recognized as reductions in Japan's greenhouse gas emissions. It should not use taxpayers' money to buy surplus emission credits from other countries in a desperate bid to achieve its numerical target.

In the medium- and long term, Japan should develop and use more renewable energy. Germany's policy of seeking to eliminate nuclear power stations is coupled with its strategy of seeking to be a leader in the field of renewable energy. The level of Japan's environmental protection technology is equal to that of Germany's. Japan has the potential to become a leader in an environment-friendly energy revolution.

The Environment Ministry estimates by 2030, approximately 330 billion kilowatts per hour can be generated in Japan solely with renewable energy if its land is fully utilized. The figure is about 30 percent of electric power currently generated throughout Japan and equal to the amount of power currently generated by all nuclear power plants across the country. Theoretically, all atomic energy used for power generation in Japan can be changed to renewable energy. It is not easy to achieve this but the government should try by setting this as a target.

Among various electric power generation methods using renewable energy sources, Japan has placed priority on solar power generation. At one point, Japan was the No. 1 country in the world in terms of the amount of power generated by solar panels. Various experiments are being conducted, such as storing electric power generated by solar panels in batteries for electric vehicles. The problem involving solar power generation is its high costs. However, as the method becomes widespread, the costs will certainly decrease.

Wind power generation is the most widespread in the world because its costs are relatively low. Japan is ranked only 12th in the world in the volume of power generated by wind power generators. There are various challenges that must be overcome, such as their noise. However, there are many such generators in the Tohoku and other regions, and their potential is particularly high. Floating wind power generators are fitted for Japan, which is surrounded by little sea with shoals. Moreover, the government should promote the introduction of geothermal power generation, which could be stable sources of electric power, and small- and medium-scale hydraulic power generation for local consumption.

One of the disadvantages of natural energy sources is that their ability to generate electric power depends on the amount of sunshine and wind and is therefore unstable. This is the main reason why electric power companies have been reluctant to connect such power generators to their power grids. To overcome this problem, power suppliers should expand their power interchange capacity between themselves and install special batteries to stabilize electric power in their respective grids. In the long run, power suppliers' regional monopoly needs to be reviewed.

Above all, reductions in energy consumption are most important. The Institute of Energy Economics, Japan estimates that by replacing all incandescent bulbs in Japan with light-emitting diode (LED) bulbs, electric power equal to that generated by four nuclear reactors can be saved. This is why it is said that "saving energy is creating energy."

Future generations will feel the limited nature of energy more than us. Japan must reform itself into a country that can efficiently function with smaller amounts of energy. The system to supply energy needs to be restructured into one based on local production for local consumption. Renewable energy is

most suitable for such an energy-supply system. Prompt action is called for to ensure energy safety and security for future generations.

(Mainichi Japan) August 3, 2011

Nuclear agency asked 2 more utilities to send staff to symposiums

TOKYO (Kyodo) -- A former senior official of Japan's nuclear safety agency acknowledged Wednesday that he asked two more power companies to mobilize their employees for government-sponsored symposiums on nuclear energy, in the latest revelations of alleged attempts to manipulate opinions at the events.

The official, who headed the public relations section at the Nuclear and Industrial Safety Agency, told Kyodo News that he made such requests to Kyushu Electric Power Co. ahead of an October 2005 symposium on the Genkai nuclear power plant in Saga Prefecture, and to Tohoku Electric Power Co. over the Onagawa plant in Miyagi Prefecture.

While the official could not specify when the Onagawa symposium was held, it is believed to be the one held in October 2006. The official also said he could not recall to whom and where he made the requests.

Meanwhile, Kyushu Electric dismissed the claim, saying it has found no record of such requests from the government after double checking with its staff and reviewing documents at the time.

A Tohoku Electric official said the company was looking into the matter and declined to comment.

Wednesday's revelations came after the official told Kyodo News a day earlier that he asked senior officials at Shikoku Electric Power Co. to make its employees attend a symposium in June 2006.

The nuclear safety agency said a third-party panel to be created shortly will look into the allegations.

(Mainichi Japan) August 3, 2011

Highest indoor radiation level detected at Fukushima Daiichi plant

In this photo released by Tokyo Electric Power Co. (TEPCO), a worker walks on the second floor of the No. 1 reactor building at the Fukushima Dai-ichi nuclear power plant in Okuma town, Fukushima Prefecture, northeastern Japan, early Monday, May 9, 2011.

TOKYO (Kyodo) -- Radiation dosages of 5 sieverts per hour were detected indoors on the second floor of the No. 1 reactor at the crisis-hit Fukushima Daiichi nuclear power plant on Tuesday, the highest figure yet indoors, plant operator Tokyo Electric Power Co. said.

The figure was detected in front of a pipe in an air-conditioning machine room, the utility said, adding the dosage may be larger than the measured amount as it exceeds the capacity of measuring equipment.

Radioactive substances are considered to be staying in the pipe after they entered there when pressure in the reactor's containment vessel was lowered on March 12, according to Tokyo Electric known as TEPCO.

The company has made the area off-limits.

TEPCO also said radiation doses of more than 10 sieverts, or 10,000 millisieverts, per hour were detected outdoors again Tuesday at the plant.

If exposed to such a high-level dosage of radiation in a short period of time, almost all people exposed would die, radiation experts said.

On Monday, Tokyo Electric said radiation doses of as high as 10 sieverts per hour were detected outside the buildings for the No. 1 and No. 2 reactors.

Gamma camera images which show radiation doses by color indicated red at the bottom of the main exhaust pipe between the two reactor buildings, which means radiation doses top 10 sieverts per hour, TEPCO said.

On Tuesday, more than 10 sieverts per hour were detected at an area near the scene, with those images also showing red at a height of 10 meters above ground on the back of the exhaust pipe.

TEPCO said radioactive substances might have adhered to the back of the exhaust pipe after they were emitted when the company vented at the No. 1 unit to lower pressures within the reactor pressure vessel and reactor container.

TEPCO said those places with high doses of radiation pose no major trouble for the company's work to contain the nuclear crisis and that **it has no plan to measure radiation doses in detail.**

On Monday, TEPCO said its plant workers confirmed the high-level doses of radioactivity Monday afternoon when they put the measuring device to the surface of the exhaust pipe. The level may have been higher than the measured amount of 10 sieverts per hour as it exceeds the capacity of measuring equipment.

This photograph shows a worker who measured radiation doses near the surface of an exhaust pipe between the No. 1 and 2 reactors at the Fukushima No. 1 Nuclear Power Plant on Aug. 1. (Photo courtesy of TEPCO)

Previously, the highest dose detected indoors was 4 sieverts per hour measured at the floor of the No. 1 reactor building.

Meanwhile, State Minister Goshi Hosono, who is in charge of the nuclear accident, called Tuesday for correctly analyzing the situation, saying at a news conference that a correct grasp is essential to settle long-term issues involving the Fukushima Daiichi plant that was crippled by the March 11 earthquake and tsunami.

Gov't to make radioactive material concentration map for farmlands

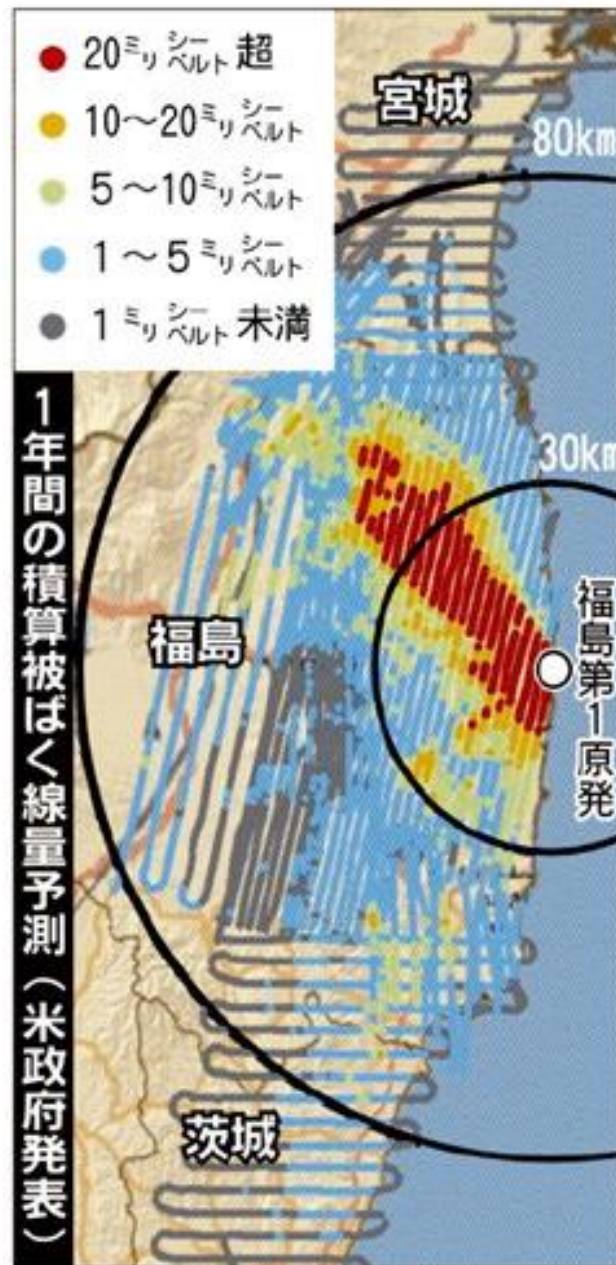

TOKYO (Kyodo)-- The government said Tuesday it plans to draw up a radioactive substance concentration map for farmlands and conduct a study on contaminated debris as part of measures to deal with radioactive material released from the crippled Fukushima Daiichi nuclear power plant.

The measures are to be implemented by the end of this year, with government ministries and agencies strengthening cooperation to deal with radiation contamination from the disaster-struck Fukushima No. 1 nuclear power plant.

But the government did not show how it will use findings from the study to decontaminate areas near the almost destroyed power plant.

According to measures compiled Tuesday, the Ministry of Agriculture, Forestry and Fisheries will analyze farm land at about 500 sites mainly in Fukushima Prefecture, where the wrecked nuclear plant is located, and draw up a radioactive material concentration map by the end of this month.

Also, the Environment Ministry is to check radioactive contaminated debris in the government-declared no-go zone near the plant.

The NNSA hazard map released by the U.S. federal government. The Fukushima No. 1 Nuclear Power Plant is marked by a white dot at right.

And the Ministry of Education, Culture, Sports, Science and Technology will install about 250 devices across Japan to monitor radioactive substances. Currently, there is just one of these devices installed in each of Japan's 47 prefectures.

By increasing the number of devices nationwide, the ministry aims to introduce a system by the end of this year to monitor levels of radioactive substances around the clock and disclose those levels to the public.

The ministry also plans to enhance studies of seawater off the coasts of Fukushima, Miyagi and Ibaraki prefectures in cooperation with the Fisheries Agency and the Japan Coast Guard.

Sellafield Mox nuclear fuel plant to close

- [Fiona Harvey](#), environment correspondent
- [guardian.co.uk](http://www.guardian.co.uk), Wednesday 3 August 2011 12.29 BST -
<http://www.guardian.co.uk/environment/2011/aug/03/sellafield-mox-plant-close>

The [Mox nuclear fuel plant at Sellafield](#) will be closed on Wednesday afternoon, with the loss of about 600 jobs.

The closure is a consequence of the [Fukushima incident in Japan](#), in March.

Workers at the plant were told on Wednesday morning that there was "considerable scope" for them to be re-employed in other parts of the Sellafield complex.

It will take several months for the plant to close fully.

The West Cumbrian mixed-oxide fuel plant has cost the taxpayer £1.4bn since it was commissioned in the early 1990s.

The plant, operated by the government-owned [Nuclear Decommissioning Authority](#), was set up to create mixed-oxide fuel for use in [nuclear power](#) plants, with its chief customers the Japanese nuclear industry, including the Fukushima complex.

The plant was built in 1996 and became operational in 2001.

NDA denied there were any repercussions for the troubled [Thorp reprocessing plant](#), although Thorp is also involved in generating Mox fuel, which is made from plutonium and uranium.

The announcement will officially be made public at 2.30pm on Wednesday afternoon.

Discussions begin on how to scrap Fukushima plant

A government-appointed panel has begun discussing the timetable for decommissioning the reactors at the Fukushima Daiichi nuclear plant.

About 30 people, including members of the Atomic Energy Commission and officials from the plant's operator, Tokyo Electric Power Company, took part in the panel's initial meeting on Wednesday.

Yuichi Hayase, who joined US researchers in studying the accident at Three Mile Island in 1979, briefed the participants on how that plant was brought under control.

Hayase explained that it took 11 years to extract all the fuel rods, as workers were coping with the world's first nuclear meltdown. It was also necessary to develop remote-controlled robots and technology to process contaminated wastewater.

Panel members discussed middle- and long-term challenges in the decommissioning process, such as how to repair the reactor containment vessels and decontaminate the buildings by remote control to enable extraction of the fuel rods.

One expert cited the need for long-term training of specialized personnel, while another said international expertise is essential in drawing up the timetable.

Kyoto University Professor Hajimu Yamana, who heads the panel, said he expects longer preparations for extracting the fuel rods, because the reactor cores at Fukushima are more badly damaged than at Three Mile Island.

The panel plans to finalize the timetable by early next year, at the end of the second stage of the process to bring the plant under control.

Wednesday, August 03, 2011 19:07 +0900 (JST)

Britain to close nuclear fuel plant due to Japan disaster

In this March 15, 2011 photo released by Tokyo Electric Power Co., smoke rises from the badly damaged Unit 3 reactor, left, next to the Unit 4 reactor covered by an outer wall at the Fukushima No. 1 nuclear complex in Okuma, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

LONDON (Kyodo) -- Britain's Nuclear Decommissioning Authority said Wednesday it is to close a nuclear fuel production facility following talks with Japanese customers.

The state-owned body said it will shut the Sellafield MOX Plant in northwest England in light of the ongoing crisis at the Fukushima Daiichi nuclear plant which was crippled by the devastating March tsunami in Japan.

The NDA, which operates the Sellafield plant, had a legal framework agreement with 10 Japanese utility firms to supply plutonium-uranium mixed oxide (MOX) fuel.

The MOX fuel was going to be made up using plutonium set aside from fuel which had already been reprocessed by Japanese utilities.

A statement from the NDA said, "The NDA Board has now assessed the changed commercial risk profile for SMP arising from potential delays following the earthquake in Japan and subsequent events."

It has concluded that "the only reasonable course of action is to close SMP at the earliest opportunity" to ensure that Britain's taxpayer does not carry a future financial burden from the plant.

An NDA spokesman said Chubu Electric Power Co.'s Hamaoka nuclear plant was to be the first user of Sellafield MOX fuel with the first shipment planned toward the end of the decade. Chubu Electric, however, shut down the plant in May at the request of the Japanese government following the Fukushima crisis.

This March 24, 2011 aerial photo taken by a small unmanned drone and released by AIR PHOTO SERVICE shows damaged Unit 3 of the crippled Fukushima Dai-ichi nuclear power plant in Okumamachi, Fukushima Prefecture, northeastern Japan. (AP Photo/AIR PHOTO SERVICE)

The spokesman said all parties agreed "with sadness" to take advantage of a break clause within the framework agreement.

He said the "small amount" of plutonium currently owned by the Japanese utilities will continue to be stored at Sellafield and discussions on its future will continue.

The Sellafield plant, which opened in 2001, carried out a few contracts for European utilities but the NDA was hoping that the Japanese contracts would ensure its long-term viability.

The British government is currently consulting on what to do with its stockpile of civilian plutonium and the preferred option is to reuse it by making new MOX fuel.

One source familiar with the issue, and speaking on condition of anonymity, told Kyodo News that this could lead to the creation of a new MOX plant. He added this could be used by the Japanese utilities if there was a change in the political climate toward nuclear power.

In 1999, a demonstration facility at Sellafield manufactured the first batch of MOX fuel for Japan and it was sent to a reactor in Takahama, Fukui Prefecture.

However, it later emerged that the quality assurance tests on the fuel had been fabricated and the consignment had to be shipped back to Britain. Compensation was paid to the client, Kansai Electric Power Co.

Since then, the Sellafield plant has been keen to win back the trust of Japanese utilities and win new MOX orders.

Following the Fukushima incident, the Japanese government has decided to review its nuclear policy with a view to reducing its dependency on this source of energy.

Gov't to require disposal of rice found cesium-tainted in 2-phase test

TOKYO (Kyodo) -- The farm ministry said Wednesday that municipalities should test rice to be locally harvested this year in two stages for possible radioactive pollution from the crippled Fukushima Daiichi nuclear power plant and dispose of all rice found to be contaminated above the government-set safety limit.

A preliminary test should be carried out about a week before harvesting in municipalities where more than 1,000 becquerels of radioactive cesium per kilogram of soil are detected or where radiation doses in the air are higher than normal levels, according to the Ministry of Agriculture, Forestry and Fisheries.

Municipalities designated by prefectural governors should also conduct the preliminary test.

The ministry will require a full-scale test to be implemented per 15 hectares of rice acreage by municipalities where more than 200 becquerels per kilogram of rice are detected in the preliminary test.

A municipality where rice tainted with cesium exceeding 500 becquerels per kilogram is confirmed in the second test will be required to issue a shipment ban and dispose of all rice cropped there, the ministry said.

Meanwhile, the Shizuoka prefectural government said neither cesium nor iodine was detected in a sample test using unmilled rice supplied by three growers in the city of Kikugawa.

The government collected 6 kg of rice, due to be cropped in August, from the growers on July 25 and sent 2 kg to a local private testing institute Tuesday.

Radiation limit for children will be lowered

The Japanese government says the yearly radiation limit for school children will be lowered as early as this month.

The government has set the limit for accumulated external radiation for children involved in outdoor activities at 20 millisieverts per year, in the wake of the Fukushima nuclear accident.

But many parents and teachers want the figure to be lowered. Some schools are restricting outdoor activities by their pupils even if radiation levels are below the government-set standard.

Education Minister Yoshiaki Takaki will visit an elementary school in Fukushima Prefecture on Thursday. He will inspect progress on work to replace the topsoil of its schoolyard and talk to school staff.

The ministry says it will make a final decision based on the outcome of the minister's tour and results of radiation monitoring in the areas near the troubled Fukushima plant. The limit will be most likely lowered in late August, when the ongoing summer recess is over.

Japan's largest labor organization questions nuclear energy policy

In this March 15, 2011 photo released by Tokyo Electric Power Co., smoke rises from the badly damaged Unit 3 reactor, left, next to the Unit 4 reactor covered by an outer wall at the Fukushima No. 1 nuclear complex in Okuma, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

HIROSHIMA (Kyodo) -- Japan's largest labor organization questioned the country's energy policy Thursday, including the promotion of nuclear power generation in the wake of the crisis at the Fukushima Daiichi plant.

"The basis of what Japan's energy policy should be, including nuclear power, is being questioned," Hiroyuki Nagumo, secretary general of **the Japanese Trade Union Confederation**, told an antinuclear gathering in Hiroshima.

"The Japanese people's trust in nuclear power generation has been lost," Nagumo told around 6,500 participants at the event organized jointly by the confederation, the Japan Congress Against A- and H-Bombs, and the National Council for Peace and Against Nuclear Weapons.

It was the first time that the confederation, known as Rengo, has mentioned the issue of nuclear energy since it began co-organizing in 2005 a series of annual peace events to commemorate the U.S. atomic bombings of Hiroshima and Nagasaki.

Hiroshima Mayor Kazumi Matsui and Hiroshima Gov. Hidehiko Yuzaki attended the gathering on Thursday.

But Nagumo did not elaborate further on the issue of nuclear energy, reflecting tensions within Rengo, which is the biggest supporter of the ruling Democratic Party of Japan and has labor unions representing workers at power utilities and nuclear reactor manufacturers under its wing.

"We have to start discussions concerning nuclear energy from the beginning to decide on what we should do in the future," Nagumo told a press conference earlier Thursday.

The confederation and the antinuclear groups have been united in opposing nuclear weapons and calling for better support measures for atomic-bomb survivors.

But the confederation and the council promoted nuclear power generation before the March 11 earthquake and tsunami crippled the Fukushima complex and led it to release a massive amount of radiation.

Rengo decided in May to freeze its policy of promoting the construction of new nuclear power plants. But the Japanese Electrical, Electronic & Information Union, a member of Rengo, called in July for restarting nuclear power reactors that have been shut down for regular checks.

Koichi Kawano, a Nagasaki atomic-bomb survivor and the head of the congress, said in his address to the event, "With many people questioning the safety of nuclear power plants, how can we go on without talking about the problem of nuclear plants?"

"A nuclear power plant accident and use of a nuclear weapon cause similar damage. Humans and atomic power cannot coexist," he said.

3 top Japanese nuclear officials axed amid nuclear crisis

TOKYO, Aug. 4, Kyodo

Japan's Economy, Trade and Industry Minister Banri Kaieda said Thursday he will sack vice minister Kazuo Matsunaga and two other top officials in charge of nuclear power to hold them responsible for the handling of the ongoing crisis at the Fukushima Daiichi nuclear power plant crippled by the March 11 earthquake and tsunami.

Kaieda said at a press conference that Nobuaki Terasaka, head of the Nuclear and Industrial Safety Agency, and Tetsuhiro Hosono, head of the Agency for Natural Resources and Energy, will also step down. Both agencies are under the Ministry of Economy, Trade and Industry.

Later in the day, the ministry announced that Kenyu Adachi, director general of the ministry's Economic and Industrial Policy Bureau, will succeed Matsunaga as vice minister on Aug. 12.

Adachi joined the Ministry of International Trade and Industry, the predecessor of METI, in 1977 and has been serving as head of the Economic and Industrial Policy Bureau, since July 2010.

Terasaka will be replaced by Hiroyuki Fukano, director general for commerce and distribution policy, on Aug. 12, while Ichiro Takahara, head of the Small and Medium Enterprise Agency, an organization under the ministry, will replace Hosono who will step down on Sept. 1 as head of the Agency for Natural Resources and Energy.

An artist's drawing of a solar power generation system that the University of Tokyo's endowed chair is planning to build in Saudi Arabia. (Courtesy of the University of Tokyo)

Kaieda told reporters in the afternoon that he has decided on the reshuffle of the personnel to drastically review nuclear regulations and promote new energy policy.

METI and the nuclear safety agency have drawn criticism for their handling of the nuclear crisis at the Fukushima plant, including delays in public announcements, power supply problems and alleged attempts to manipulate public opinion to show support for nuclear power.

The appointments will be officially announced following approval at a Cabinet meeting on Friday.

Adachi will be succeeded by Norihiko Ishiguro, head of the Commerce and Information Policy Bureau, as head of the Economic and Industrial Policy Bureau, while Takahara will be replaced by Masanori Suzuki, head of the Manufacturing Industries Bureau, as head of the Small and Medium Enterprise Agency.

Chief Cabinet Secretary Yukio Edano said at a press conference on Thursday that Kaieda reported the planned reshuffle of personnel to Prime Minister Naoto Kan on Tuesday but he did not refer to his resignation at that time.

(Mainichi Japan) August 5, 2011

Last year's rice being hoarded over radiation contamination worries

TOKYO (Kyodo) -- Consumers are beginning to hoard last year's rice as their dietary staple over concerns that freshly harvested rice may be contaminated with radioactive materials released from the troubled Fukushima Daiichi nuclear power plant, retailers said Friday.

The Agriculture, Forestry and Fisheries Ministry is working to establish a system for ensuring the safety of rice ahead of the harvest season in autumn, with plans to inspect the crop in two stages.

The buying spree, however, indicates deep public distrust of the government's handling of food safety issues in the wake of the nuclear crisis following a scare over contaminated beef.

A rice seller in Tokyo's Nerima Ward said regular customers began asking it to keep rice on stock just around the time the ministry disclosed its rice inspection plans on Wednesday.

A supermarket in Koto Ward, also Tokyo, said rice is selling at twice the normal pace at the outlet, while various rice brands were mostly sold out at a nearby shopping center.

"It's like a rice panic," said a store clerk at a supermarket in Chuo Ward, noting that given the strong demand for old rice, wholesalers are hesitant about quickly releasing their stock.

According to Kitoku Shinryo Co., a major rice wholesaler based in Tokyo, rice from the previous year does not sell much around this time of year ahead of the arrival on the market of freshly harvested rice. Retailers therefore tend to refrain from stocking it at their outlets, it said.

Noting that rice, which is mostly marketed after polishing, is not the kind of produce likely to show levels of contamination above the allowable limit, a Kitoku Shinryo official said, "The panic will probably subside once fresh rice starts to go around."

Some retailers are concerned, however, about how consumers would react if radioactive materials are found in rice even at levels below the limit.

"I know an acquaintance who has hoarded rice from last year," said a 53-year-old woman who was shopping at a mall in Tokyo's Koto Ward. "I would be lying if I said I'm not worried, because it's a staple."

Consumers are apparently motivated in part by their mistrust of the government for the way it has handled the contamination of cattle with radioactive cesium and the distribution of affected beef.

A 47-year-old designer in Chuo Ward said he believes that consumers must do what they can to protect themselves. "Contaminated beef got into the distribution chain. It would be too late if we were told afterwards that there were (excessive levels of radioactive materials in rice) after all."

Frazer-Nash helps EDF Energy to improve the UK's AGRs

5 August 2011

Engineering consultancy Frazer-Nash is providing support to **an experiment as part of an EDF Energy project to extend the life of the UK's advanced gas-cooled nuclear reactors (AGRs), which has long been a strategic priority for EDF.**

The study, being undertaken at the Materials Test Reactor in Petten, Holland, will see the engineering experts providing technical support and interpreting materials data for integration into EDF Energy's AGR safety case.

The experiment has been designed to accelerate the rate of material degradation, in order to simulate how the integrity of these materials within an AGR reactor will be affected over a longer period of time.

With the first phase of the project underway, Frazer-Nash is currently advising EDF Energy on what samples to put into the test reactor, as well as which types of environments to expose them to.

Read more: <http://www.theengineer.co.uk/sectors/energy-and-environment/frazer-nash-helps-edf-energy-to-improve-the-uks-agrs/1009587.article#ixzz1UFzXiAmm>

Sellafield High Level Waste (HLW) shipment sails for earthquake region of Japan

[3 August 2011] <http://www.corecumbria.co.uk/default.htm>

Sellafield High Level Waste (HLW) shipment sails for earthquake region of Japan □ a direct threat not only to the people and environment of Japan, but also to en-route communities in the Caribbean and Pacific and their marine environment.

The shipment, which comes less than five months after the devastating earthquake and tsunami hit the Pacific coast of northern Japan, and while the Fukushima-daiichi nuclear meltdown and accident is on-going, left the port of Barrow-in-Furness at approximately 0200 hrs this morning. **The cargo of nuclear waste is bound for Aomori, north-eastern Japan via the Caribbean and the Panama Canal.**

The vitrified HLW, delivered by rail from Sellafield in three TN28VT transport flasks yesterday, was loaded onto the **Pacific Grebe**, a British-flagged ship operated by Pacific Nuclear Transport Limited (PNTL). **Within the transport flasks were 76 cannisters of vitrified HLW, totalling over 40 tonnes of highly radioactive waste** which has been assigned to the Kansai, Shikoku and Kyushu Electric Power Companies in Japan respectively.

Last month CARICOM, which represents the nations of the Caribbean, had demanded a halt to all shipments in a statement condemning □ as unacceptable and injurious, the practice by the United Kingdom, France and Japan of transporting hazardous waste through the Caribbean Sea, thus risking the very existence of the people of the Caribbean □. The Pacific Grebe, making her maiden voyage to Japan, is expected to arrive in the Caribbean in mid-August, the Panama Canal on 18th August, and its HLW cargo scheduled to arrive in the port of Mutsu-Ogawara around 25th September.

CORE □'s spokesman Martin Forwood said today: □ It is incomprehensible that whilst Japan, its people and environment continue to suffer daily from the still unfolding Fukushima catastrophe, Sellafield should see fit to add to the country □'s woes by sending nuclear waste. This unwanted shipment of the most radioactive material on the planet is also being made in flagrant disregard of the long-standing opposition to such shipments by the Caribbean nations and others en-route. These dangerous transports are wholly unnecessary and must be stopped □.

The high level waste results from the reprocessing of Japanese spent reactor fuel at the Sellafield site in NW England □ the process which also recovers plutonium. Under contracts signed in the 1970's and 1980's, Japanese nuclear power companies shipped the waste to the UK and France for reprocessing with some of the waste and all of the plutonium to be returned. **The HLW, in glass block form, is sufficiently radioactive to deliver a lethal radiation dose to a person standing within one metre of an unshielded block in less than one minute.**

Today □'s shipment is the second return of HLW to Japan, the first undertaken early last year when 14 tonnes in one transport flask were returned on the Pacific Sandpiper. Some 15 years

late, these waste returns to overseas reprocessing customers were originally scheduled to be made in the mid-1990s.

A shipment of plutonium MOX fuel was scheduled to leave France the first week of April 2011 for Japan, including Fukushima. Due to the earthquake, tsunami and nuclear accident it was cancelled after it was revealed by Greenpeace France.

Gov't eyes halving area of high annual radiation exposure in 2 yrs

TOKYO (Kyodo) -- The government is considering setting a decontamination target of halving by March 2013 the area in which residents may be exposed to over 20 millisieverts of radiation a year as a result of the nuclear crisis at the Fukushima Daiichi power plant, informed sources said.

The goal for the two-year period after the nuclear crisis triggered at the plant by the March 11 earthquake and tsunami will be incorporated into a package of key decontamination goals that the government is expected to adopt and announce shortly, the sources said.

The government is drawing up the package to enable residents of Fukushima Prefecture who have evacuated due to radiation to return to their homes, the sources said.

The package, if adopted, would also set a "long-term" goal of reducing the annual radiation exposure of residents to 1 millisievert or less.

Prime Minister Naoto Kan told a news conference Saturday that the government "would like to implement thorough decontamination, while conducting firm monitoring" of the situation.

Decontamination entails the cleaning of buildings and road surfaces as well as the removal of mud and soil. There is a possibility that some of the water used in the decontamination process and mud removed from roadside ditches could contain large amounts of radioactive substances.

While the decontamination operations proceed, the country could be faced with a new problem of how to store and dispose of the contaminated water, mud and soil, they said.

Under the draft package, the government is considering classifying contaminated areas into three categories according to radiation level, they said.

Under the draft, the central government would be responsible for areas where radiation exposure is expected to top 20 millisieverts a year, while municipal governments would be responsible for areas where exposure would likely range between 1 to 20 millisieverts.

In areas where exposure of 1 millisievert or less is expected, residents themselves would be responsible for decontamination in line with safety guidelines devised by the government.

According to the road map drawn up by the government and Tokyo Electric Power Co. to bring the nuclear crisis under control, the plant's stabilization process is currently going through the "step two" stage, which is expected to last for 3 to 6 months from July.

Under the road map, TEPCO is seeking to reduce temperatures at the bottom of reactor pressure vessels to 100 C or less and to halt the release of radioactive substances from reactor containment vessels.

(Mainichi Japan) August 7, 2011

Underground electric cable damaged during survey at Fukushima plant

TOKYO (Kyodo) -- Tokyo Electric Power Co. said that an underground electric cable at the Fukushima No. 1 Nuclear Power Plant was erroneously damaged while workers were conducting a boring survey as part of efforts to prevent leakage of radiation-contaminated water into the sea.

The utility known as TEPCO discovered the development during an investigation into a power outage that occurred Thursday at an isolated building that serves as a base for bringing the disaster-triggered nuclear crisis at the plant under control, it said.

After the power failure occurred at the building at around 12:50 p.m. Thursday, backup power was activated a minute later to resume electricity supply and the normal power source was resumed about three and a half hours later, according to TEPCO.

In the survey, being taken before workers place shields in the ground to prevent contaminated water from flowing into the sea, workers were boring into the ground to check the flow of groundwater when a device touched and damaged the electric cable about 2.5 meters underground, it said.

TEPCO officials said they will check underground charts beforehand in continuing the survey.

(Mainichi Japan) August 7, 2011

Water treatment system at Fukushima plant stops for 7.5 hours, cause unknown

Tokyo Electric Power Co. (TEPCO) said a radioactive water treatment system at the Fukushima No. 1 Nuclear Power Plant stopped operating for 7.5 hours shortly after 8 a.m. on Aug. 7, prompting the Nuclear and Industrial Safety Agency (NISA) to instruct the utility to come up with preventative measures.

While the water treatment system was out of operation, processed water was used to cool down reactors, TEPCO, the operator of the crippled nuclear power station in Fukushima, said on Aug. 7. According to the utility, the trouble occurred in a water decontamination device developed by France's Areva SA. It said one of the pumps used in two separate water treatment systems to inject chemicals aiding precipitation of radioactive cesium stopped operating. In a similar development, another pump also stopped operating due to a glitch on Aug. 4.

Internal investigations found that the pump stopped operating on Aug. 7 because sticky chemicals injected into it had put too much of a load on it. The pump's operations resumed at around 3:30 p.m. on Aug. 7, after the amount of chemicals in each injection was reduced while the frequency of injections was increased. TEPCO suspects that the other pump may have stopped operating for the same cause on Aug. 4.

Each of the two water treatment systems has one pump for operations under normal conditions and a backup pump for use in times of trouble. The backup pumps in the two systems failed to operate on Aug. 4 and 7, respectively. Engineers are checking the system for the cause of the trouble.

Following a string of problems with the pumps, NISA instructed TEPCO to investigate the causes of the mishaps. The agency urged the utility to work out and submit preventative plans as well as to report a list of troubles other than those with the pumps.

At the same time, TEPCO for the first time started operating newly installed equipment to evaporate and concentrate saltwater within two of its eight water-treatment systems. The equipment is used to reduce the volume of highly concentrated saltwater that comes from a desalination device within the water treatment system. The volume of highly concentrated saltwater coming from the desalination device is about 1.5 times as much as that of desalinated water. The volume of highly concentrated saltwater is said to be reduced to about 30 percent by using the newly installed equipment

(Mainichi Japan) August 8, 2011

Govt to put nuke watchdog under Environment Min.

Japan's government has decided to establish a new nuclear watchdog under the Environment Ministry.

The decision was made at a meeting of Cabinet ministers on Friday as part of efforts to review the country's current nuclear administration following the Fukushima nuclear accident.

The ministers decided that the Nuclear and Industrial Safety Agency should be separated from the industry ministry, which promotes nuclear energy.

The ministers agreed to merge the agency with the Nuclear Safety Commission, currently under the Cabinet Office, and monitoring functions of the Education and Science Ministry.

The Environment Ministry has been handling disposal of radiation-contaminated debris around the damaged Fukushima Daiichi nuclear plant.

The new agency is expected to use the ministry's local offices to oversee nuclear reactors across the country and collaborate with local governments.

The government plans to submit related bills to the Diet early next year and launch the new agency in April.

Japan Held Nuclear Data, Leaving Evacuees in Peril

By [NORIMITSU ONISHI](#) and [MARTIN FACKLER](#)

FUKUSHIMA, Japan — The day after a giant tsunami set off the continuing disaster at the Fukushima Daiichi nuclear plant, thousands of residents at the nearby town of Namie gathered to evacuate.

Given no guidance from Tokyo, town officials led the residents north, believing that winter winds would be blowing south and carrying away any radioactive emissions. For three nights, while hydrogen explosions at four of the reactors spewed radiation into the air, they stayed in a district called Tsushima where the children played outside and some parents used water from a mountain stream to prepare rice.

The winds, in fact, had been blowing directly toward Tsushima — and town officials would learn two months later that a government computer system designed to predict the spread of radioactive releases had been showing just that.

But the forecasts were left unpublicized by bureaucrats in Tokyo, operating in a culture that sought to avoid responsibility and, above all, criticism. Japan's political leaders at first did not know about the system and later played down the data, apparently fearful of having to significantly enlarge the evacuation zone — and acknowledge the accident's severity.

"From the 12th to the 15th we were in a location with one of the highest levels of radiation," said Tamotsu Baba, the mayor of Namie, which is about five miles from the nuclear plant. He and thousands from Namie now live in temporary housing in another town, Nihonmatsu. "We are extremely worried about internal exposure to radiation."

The withholding of information, he said, was akin to "murder."

In interviews and public statements, some current and former government officials have admitted that Japanese authorities engaged in a pattern of withholding damaging information and denying facts of the nuclear disaster — in order, some of them said, to limit the size of costly and disruptive evacuations in land-scarce Japan and to avoid public questioning of the politically powerful nuclear industry. As the nuclear plant continues to release radiation, some of which has slipped into the nation's food supply, public anger is growing at what many here see as an official campaign to play down the scope of the accident and the potential health risks.

Seiki Soramoto, a lawmaker and former nuclear engineer to whom Prime Minister Naoto Kan turned for advice during the crisis, blamed the government for withholding forecasts from the computer system, known as the System for Prediction of Environmental Emergency Dose Information, or Speedi.

"In the end, it was the prime minister's office that hid the Speedi data," he said. "Because they didn't have the knowledge to know what the data meant, and thus they did not know what to say to the public, they thought only of their own safety, and decided it was easier just not to announce it."

In an interview, Goshi Hosono, the minister in charge of the nuclear crisis, dismissed accusations that political considerations had delayed the release of the early Speedi data. He said that they were not disclosed because they were incomplete and inaccurate, and that he was presented with the data for the first time only on March 23.

“And on that day, we made them public,” said Mr. Hosono, who was one of the prime minister’s closest advisers in the early days of the crisis before being named nuclear disaster minister. “As for before that, I myself am not sure. In the days before that, which were a matter of life and death for Japan as a nation, I wasn’t taking part in what was happening with Speedi.”

The computer forecasts were among many pieces of information the authorities initially withheld from the public.

Meltdowns at three of Fukushima Daiichi’s six reactors went officially unacknowledged for months. In one of the most damning admissions, nuclear regulators said in early June that inspectors had found tellurium 132, which experts call telltale evidence of reactor meltdowns, a day after the tsunami — but did not tell the public for nearly three months. For months after the disaster, the government flip-flopped on the level of radiation permissible on school grounds, causing continuing confusion and anguish about the safety of schoolchildren here in Fukushima.

Too Late

The timing of many admissions — coming around late May and early June, when inspectors from the International Atomic Energy Agency visited Japan and before Japan was scheduled to deliver a report on the accident at an I.A.E.A. conference — suggested to critics that Japan’s nuclear establishment was coming clean only because it could no longer hide the scope of the accident. On July 4, the Atomic Energy Society of Japan, a group of nuclear scholars and industry executives, said, “It is extremely regrettable that this sort of important information was not released to the public until three months after the fact, and only then in materials for a conference overseas.”

The group added that the authorities had yet to disclose information like the water level and temperature inside reactor pressure vessels that would yield a fuller picture of the damage. Other experts have said the government and Tokyo Electric Power Company, known as Tepco, have yet to reveal plant data that could shed light on whether the reactors’ cooling systems were actually knocked out solely by the 45-foot-tall tsunami, as officials have maintained, or whether damage from the earthquake also played a role, a finding that could raise doubts about the safety of other nuclear plants in a nation as seismically active as Japan.

Government officials insist that they did not knowingly imperil the public.

“As a principle, the government has never acted in such a way as to sacrifice the public’s health or safety,” said Mr. Hosono, the nuclear disaster minister.

Here in the prefecture’s capital and elsewhere, workers are removing the surface soil from schoolyards contaminated with radioactive particles from the nuclear plant. Tens of thousands of children are being kept inside school buildings this hot summer, where some wear masks even though the windows are kept shut. Many will soon be wearing individual dosimeters to track their exposure to radiation.

At Elementary School No. 4 here, sixth graders were recently playing shogi and go, traditional board games, inside. Nao Miyabashi, 11, whose family fled here from Namie, said she was afraid of radiation. She tried not to get caught in the rain. She gargled and washed her hands as soon as she got home.

“I want to play outside,” she said.

About 45 percent of 1,080 children in three Fukushima communities surveyed in late March tested positive for thyroid exposure to radiation, according to a recent announcement by the government, which added that the levels were too low to warrant further examination. Many experts both in and outside Japan are questioning the government’s assessment, pointing out that in Chernobyl, most of those who went on to suffer from [thyroid cancer](#) were children living near that plant at the time of the accident.

Critics inside and outside the Kan administration argue that some of the exposure could have been prevented if officials had released the data sooner.

On the evening of March 15, Mr. Kan called Mr. Soramoto, who used to design nuclear plants for Toshiba, to ask for his help in managing the escalating crisis. Mr. Soramoto formed an impromptu advisory group, which included his former professor at the University of Tokyo, Toshiso Kosako, a top Japanese expert on radiation measurement.

Mr. Kosako, who studied the Soviet response to the Chernobyl crisis, said he was stunned at how little the leaders in the prime minister’s office knew about the resources available to them. He quickly advised the chief cabinet secretary, Yukio Edano, to use Speedi, which used measurements of radioactive releases, as well as weather and topographical data, to predict where radioactive materials could travel after being released into the atmosphere.

Speedi had been designed in the 1980s to make forecasts of radiation dispersal that, according to the prime minister’s office’s own nuclear disaster manuals, were supposed to be made available at least to local officials and rescue workers in order to guide evacuees away from radioactive plumes.

And indeed, Speedi had been churning out maps and other data hourly since the first hours after the catastrophic earthquake and tsunami. But the Education Ministry had not provided the data to the prime minister’s office because, it said, the information was incomplete. The tsunami had knocked out sensors at the plant: without measurements of how much radiation was actually being released by the plant, they said, it was impossible to measure how far the radioactive plume was stretching.

“Without knowing the strength of the releases, there was no way we could take responsibility if evacuations were ordered,” said Keiji Miyamoto of the Education Ministry’s nuclear safety division, which administers Speedi.

The government had initially resorted to drawing rings around the plant, evacuating everyone within a radius of first 1.9 miles, then 6.2 miles and then 12.4 miles, widening the rings as the scale of the disaster became clearer.

But even with incomplete data, Mr. Kosako said he urged the government to use Speedi by making educated guesses as to the levels of radiation release, which would have still yielded usable maps to

guide evacuation plans. In fact, the ministry had done precisely that, running simulations on Speedi's computers of radiation releases. Some of the maps clearly showed a plume of nuclear contamination extending to the northwest of the plant, beyond the areas that were initially evacuated.

However, Mr. Kosako said, the prime minister's office refused to release the results even after it was made aware of Speedi, because officials there did not want to take responsibility for costly evacuations if their estimates were later called into question.

A wider evacuation zone would have meant uprooting hundreds of thousands of people and finding places for them to live in an already crowded country. Particularly in the early days after the earthquake, roads were blocked and trains were not running. These considerations made the government desperate to limit evacuations beyond the 80,000 people already moved from areas around the plant, as well as to avoid compensation payments to still more evacuees, according to current and former officials interviewed.

Mr. Kosako said the top advisers to the prime minister repeatedly ignored his frantic requests to make the Speedi maps public, and he resigned in April over fears that children were being exposed to dangerous radiation levels.

Some advisers to the prime minister argue that the system was not that useful in predicting the radiation plume's direction. Shunsuke Kondo, who heads the Atomic Energy Commission, an advisory body in the Cabinet Office, said that the maps Speedi produced in the first days were inconsistent, and changed several times a day depending on wind direction.

"Why release something if it was not useful?" said Mr. Kondo, also a retired professor of nuclear engineering at the University of Tokyo. "Someone on the ground in Fukushima, looking at which way the wind was blowing, would have known just as much."

Mr. Kosako and others, however, say the Speedi maps would have been extremely useful in the hands of someone who knew how to sort through the system's reams of data. He said the Speedi readings were so complex, and some of the predictions of the spread of radiation contamination so alarming, that three separate government agencies — the Education Ministry and the two nuclear regulators, the Nuclear and Industrial Safety Agency and Nuclear Safety Commission — passed the data to one another like a hot potato, with none of them wanting to accept responsibility for its results.

In interviews, officials at the ministry and the agency each pointed fingers, saying that the other agency was responsible for Speedi. The head of the commission declined to be interviewed.

Mr. Baba, the mayor of Namie, said that if the Speedi data had been made available sooner, townspeople would have naturally chosen to flee to safer areas. "But we didn't have the information," he said. "That's frustrating."

Evacuees now staying in temporary prefabricated homes in Nihonmatsu said that, believing they were safe in Tsushima, they took few precautions. Yoko Nozawa, 70, said that because of the lack of toilets, they resorted to pits in the ground, where doses of radiation were most likely higher.

"We were in the worst place, but didn't know it," Ms. Nozawa said. "Children were playing outside."

A neighbor, Hiroyuki Oto, 31, said he was working at the plant for a Tepco subcontractor at the time of the earthquake and was now in temporary lodging with his wife and three young children, after also staying in Tsushima. “The effects might emerge only years from now,” he said of the exposure to radiation. “I’m worried about my kids.”

Seeds of Mistrust

Mr. Hosono, the minister charged with dealing with the nuclear crisis, has said that certain information, including the Speedi data, had been withheld for fear of “creating a panic.” In an interview, Mr. Hosono — who now holds nearly daily news conferences with Tepco officials and nuclear regulators — said that the government had “changed its thinking” and was trying to release information as fast as possible.

Critics, as well as the increasingly skeptical public, seem unconvinced. They compare the response to the Minamata case in the 1950s, a national scandal in which bureaucrats and industry officials colluded to protect economic growth by hiding the fact that a chemical factory was releasing mercury into Minamata Bay in western Japan. The mercury led to neurological illnesses in thousands of people living in the region and was captured in wrenching photographs of stricken victims.

“If they wanted to protect people, they had to release information immediately,” said Reiko Seki, a sociologist at Rikkyo University in Tokyo and an expert on the cover-up of the Minamata case. “Despite the experience with Minamata, they didn’t release Speedi.”

In Koriyama, a city about 40 miles west of the nuclear plant, a group of parents said they had stopped believing in government reassurances and recently did something unthinkable in a conservative, rural area: they sued. Though their suit seeks to force Koriyama to relocate their children to a safer area, their real aim is to challenge the nation’s handling of evacuations and the public health crisis.

After the nuclear disaster, the government raised the legal exposure limit to radiation from one to 20 millisieverts a year for people, including children — effectively allowing them to continue living in communities from which they would have been barred under the old standard. The limit was later scaled back to one millisievert per year, but applied only to children while they were inside school buildings.

The plaintiffs’ lawyer, Toshio Yanagihara, said the authorities were withholding information to deflect attention from the nuclear accident’s health consequences, which will become clear only years later.

“Because the effects don’t emerge immediately, they can claim later on that [cigarettes](#) or coffee caused the [cancer](#),” he said.

The Japanese government is considering monitoring the long-term health of Fukushima residents and taking appropriate measures in the future, said Yasuhiro Sonoda, a lawmaker and parliamentary secretary of the Cabinet Office. The mayor of Koriyama, Masao Hara, said he did not believe that the government’s radiation standards were unsafe. He said it was “unrealistic” to evacuate the city’s 33,000 elementary and junior high school students.

But Koriyama went further than the government's mandates, removing the surface soil from its schools before national directives and imposing tougher inspection standards than those set by the country's education officials.

"The Japanese people, after all, have a high level of knowledge," the mayor said, "so I think information should be disclosed correctly and quickly so that the people can make judgments, especially the people here in Fukushima."

Norimitsu Onishi reported from Fukushima, and Martin Fackler from Tokyo. Ken Belson and Kantaro Suzuki contributed reporting from Tokyo.

Excessive radioactive cesium found in Fukushima fish: Greenpeace

TOKYO (Kyodo) -- Fish caught at a port about 55 kilometers from the crippled Fukushima Daiichi nuclear power plant contained radioactive cesium at levels exceeding an allowable limit, the environmental group Greenpeace said Tuesday.

The samples taken at Onahama port in Iwaki, Fukushima Prefecture, in late July, included a species of rockfish that measured 1,053 becquerels per kilogram. The reading, the highest among the samples, is well in excess of the government-set limit of 500 becquerels per kilogram, according to a study conducted by the environmental group.

The other samples, which were all rock trout, measured between 625 and 749 becquerels per kilogram, again exceeding the provisional limit.

The second such study of marine products was conducted over three days from July 22 in Iwaki and the town of Shinchi with cooperation of fishermen and those related to the fisheries industry in Fukushima. A total of 21 samples taken in the study were analyzed at a research institute in France, according to the group.

"There is no allowable limit for internal exposure that can conclusively be said not to pose any problems," Greenpeace said in a petition submitted to Prime Minister Naoto Kan on Tuesday, noting the need to keep consumption of the food containing elevated levels of radioactive materials to a minimum.

The petition also calls for tougher marine-product monitoring and for requiring businesses to display the level of radioactive materials contained in food products on the label.

Study says nuclear fuel at Fukushima reactor possibly melted twice

In this March 15, 2011 photo released by Tokyo Electric Power Co., smoke rises from the badly damaged Unit 3 reactor, left, next to the Unit 4 reactor covered by an outer wall at the Fukushima No. 1 nuclear complex in Okuma, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

TOKYO (Kyodo) -- Fuel inside one of the reactors at the crippled nuclear complex in Fukushima Prefecture, which was believed to have been kept cool at the bottom of the pressure vessel after its core suffered a meltdown, has possibly breached the vessel after melting again at the bottom of the vessel, an expert's study showed Monday.

The study by Fumiya Tanabe, an expert in nuclear safety, said most of the fuel at the No. 3 reactor may have fallen into the containment vessel underneath, and if so, the current method used to cool the reactor would need reviewing, which could force the plant operator to revise its schedule to contain the five-month-old disaster.

The plant operator, Tokyo Electric Power Co. earlier said the Nos. 1 to 3 reactors' cores are assumed to have suffered meltdowns, although the melted fuel is believed to be kept cool and solidified at the bottom of each reactor pressure vessel after water was injected into the vessel as an emergency measure.

After analyzing data made public by the operator, known as TEPCO, Tanabe argues that it became difficult to inject coolant water into the reactor's pressure vessel after pressure rose inside it from the early hours of March 21.

This March 24, 2011 aerial photo taken by a small unmanned drone and released by AIR PHOTO SERVICE shows damaged Unit 3 of the crippled Fukushima Dai-ichi nuclear power plant in Okumamachi, Fukushima Prefecture, northeastern Japan. (AP Photo/AIR PHOTO SERVICE)

He says the fuel at the bottom of the pressure vessel overheated and melted again during a four-day period from March 21 when only 11 to 32 percent of the water needed to cool the fuel was injected into the pressure vessel.

Elevated levels of radiation were actually detected for several days from March 21 in the Tohoku region, in which the Fukushima Daiichi power plant is located, and the nearby Kanto region, which includes Tokyo and its surrounding area.

"I presume that the fuel fell to the bottom of the containment vessel made of concrete and reacted violently with its cement, releasing large amounts of radioactive materials into the outside from the pressure vessel," said Tanabe.

TEPCO, meanwhile, casts doubt on Tanabe's assertion, saying most of the fuel probably remains inside the reactor's pressure vessel as temperature fluctuations were observed depending on the amount of water injected into it.

TEPCO to begin building cover over Fukushima reactor Wed.

TOKYO (Kyodo) -- The operator of the crippled Fukushima Daiichi nuclear power plant said Tuesday it will begin in earnest on Wednesday work to install **a giant covering over the plant's No. 1 reactor**, with plans to complete it by the end of next month.

The covering, a tent-like structure made of steel frames and air-tight polyester sheets, is meant to prevent radioactive materials from spreading from the crippled reactor and stop rainwater from entering the reactor building, said Tokyo Electric Power Co.

When completed, the covering will be between 42 and 47 meters long and about 54 meters high. About 60 components are being brought to the seaside plant via the Pacific.

On Wednesday, a steel structure about 6.9 meters high that weighs about 30 tons is expected to be pulled up by a crane and installed at the southeast corner of the No. 1 reactor building.

The building housing the No. 1 reactor and those housing the Nos. 3 and 4 reactors at the plant were badly damaged due to explosions after tsunami caused by a magnitude 9.0 earthquake struck the plant on March 11.

Once the installation is completed at the reactor, Tokyo Electric will consider installing similar coverings for the Nos. 3 and 4 reactors, the operator said.

Giant tent to go up over Japan nuclear reactor

In this Wednesday, Aug. 10, 2011 photo released by Tokyo Electric Power Co., building materials are pulled up by a crane by the No. 1 reactor, seen behind the crane, to build a tent to cover the reactor at the crippled Fukushima No. 1 Nuclear Power Plant in Okuma, Fukushima Prefecture. (AP Photo/TEPCO)

TOKYO (AP) -- The operator of Japan's damaged Fukushima Dai-ichi nuclear power plant is building a huge tent to cover one of the worst-hit reactors, officials said Friday.

Officials hope the cover will keep radioactive materials that have already leaked from spreading, prevent rainwater seepage and offer a barrier from possible leaks or blasts in the future.

The tent is being erected to provide a temporary replacement for the No. 1 reactor's outer housing shell, which was destroyed in an explosion caused by high pressure the day after Japan's deadly earthquake and tsunami on March 11.

Construction of the tent and its foundation began this week, Koji Watanabe, a spokesman for the power utility, said Friday.

The work couldn't begin until now because the location was too dangerous for workers to operate in.

The tent is made up of airtight polyester. It will stand 177 feet (54 meters) tall and stretch 154 feet (47 meters) in length. It is held up by a metal frame.

Tokyo Electric Power Co. officials have struggled to come up with ways to mitigate the dangers from the plant since the disaster struck five months ago, sending reactors into meltdowns, releasing radiative particles into the environment and causing the world's worst nuclear crisis since Chernobyl in 1986.

Work at the plant has been hindered by the continuing threat of radiation to workers.

Earlier this month, TEPCO said an area where potentially lethal levels of radiation were detected near Unit 1 has been sealed.

It said radiation exceeded 10 sieverts -- 40 times the highest level allowed for an emergency workers to be exposed to -- at two locations near a duct connected to a ventilation stack. The area required no immediate work and was closed off.

If the tent over reactor No. 1 proves successful, similar coverings will be constructed over other reactors on the plant. The areas around the other reactors are also highly risky to work in.

The tent is expected to be completed by the end of September, Watanabe said.

Outgoing nuclear agency chief was aware of possible meltdown at Fukushima plant

Nobuaki Terasaka, outgoing director general of the Nuclear and Industrial Safety Agency (NISA), said Aug. 10 that he was aware of the possibility of a meltdown at the Fukushima No. 1 Nuclear Power Plant due to the detection of cesium on March 12, a day after the Great East Japan Earthquake and tsunami crippled the plant.

"I thought the possibility (of a meltdown) cannot be ruled out," Terasaka said at a news conference. His comment drew close attention because a NISA spokesman in March was replaced shortly after he admitted such a possibility.

The government said in June that the No. 1 to 3 reactor cores experienced meltdowns shortly after the March 11 natural disasters.

In this image released Saturday, April 16, 2011, by Tokyo Electric Power Co., top of the container of the nuclear reactor, painted in yellow, of Unit 4 at the Fukushima Dai-ichi Nuclear Plant is observed from its side with a T-Hawk drone Friday, April 15, 2011 in Okuma, Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

Asked about NISA's handling of the nuclear crisis, he said, "I am really sorry as a representative of a regulatory agency to know that many people have evacuated and are inconvenienced. There has been criticism about the results, but I have done my best."

As for NISA's response to the loss of all of the Fukushima plant's power sources and the evacuation of residents near and around the stricken plant, Terasaka said only that an investigation committee is looking into those issues.

Regarding the delay in releasing radiation forecast data, known as the System for Prediction of Environmental Emergency Dose Information (SPEEDI), the NISA chief said he knew just before the

official announcement. He also said he was aware of the criticism that he rarely held news conferences after the outbreak of the nuclear crisis.

This Saturday May 7, 2011 image from video footage released on Sunday May 8, 2011 by Tokyo Electric Power Co., shows spent fuel storage pool of the Unit 4 reactor building at the crippled Fukushima Dai-ichi nuclear power plant in Okuma town, Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

Terasaka will be relieved of his duties on Aug. 12 over the handling of the nuclear crisis as well as over e-mail campaigns to solicit opinions in favor of nuclear power plants and projects ahead of state-sponsored symposiums.

Kazuo Matsunaga, administrative vice minister of the Ministry of Economy, Trade and Industry (METI) and Tetsuhiro Hosono, director general of the Agency for Natural Resources and Energy, will be sacked along with Terasaka in connection with the nuclear crisis. Both NISA and the Agency for Natural Resources and Energy are under METI's wings.

Sasebo mayor urges gov't to dispose of nuke waste at U.S. Navy base

TOKYO (Kyodo) -- The mayor of Sasebo, which hosts a U.S. Navy base, urged the central government Friday to swiftly dispose of low-level radioactive waste found to have been stored at the military facility, which was gathered during the U.S. forces' relief operations after the March 11 earthquake-tsunami disaster in northeastern Japan.

Sasebo Mayor Norio Tomonaga told reporters after meeting with Parliamentary Vice Foreign Minister Ikuro Yamahana that he protested at the central government's failure to notify the city on the storage of the nuclear waste at the Navy base.

The low-level radioactive waste includes cleaning cloths and other items used by the navy when decontaminating aircraft deployed to the quake and tsunami devastated areas in northeastern Japan during the Operation Tomodachi relief activities, according to the city in southwestern Japan.

The radioactive substances are believed to have spewed from the crippled Fukushima Daiichi nuclear plant.

"If those materials are being properly handled, the government should first disclose information, and reassure local citizens. It is never good to provide information later," the mayor said.

Yamahana apologized for the lack of the government contact on the matter and pledged to appropriately handle the waste, Tomonaga said.

The nuclear waste poses no harm to human bodies since its radiation amount is 3.2 microsieverts, he added.

(Mainichi Japan) August 12, 2011

Govt to put nuke watchdog under Environment Min.

Japan's government has decided to establish a new nuclear watchdog under the Environment Ministry.

The decision was made at a meeting of Cabinet ministers on Friday as part of efforts to review the country's current nuclear administration following the Fukushima nuclear accident.

The ministers decided that the Nuclear and Industrial Safety Agency should be separated from the industry ministry, which promotes nuclear energy.

The ministers agreed to merge the agency with the Nuclear Safety Commission, currently under the Cabinet Office, and monitoring functions of the Education and Science Ministry.

The Environment Ministry has been handling disposal of radiation-contaminated debris around the damaged Fukushima Daiichi nuclear plant.

The new agency is expected to use the ministry's local offices to oversee nuclear reactors across the country and collaborate with local governments.

The government plans to submit related bills to the Diet early next year and launch the new agency in April.

Radiation contamination leaves Fukushima schools unable to drain pool water

Many schools in Fukushima Prefecture are at a loss over what do to with their swimming pools, which can't be used or drained because the water is tainted with radioactive materials from the Fukushima No. 1 Nuclear Power Plant, it has emerged.

The Ministry of Education, Culture, Sports, Science and Technology has said schools should obtain consent from farmers when draining pool water into agricultural waterways, but the Fukushima Prefectural Board of Education has not formed any guidelines on the concentration of radiation in water that is drained -- leaving locals to sort out the issue themselves.

According to the education board, about 600 of the 735 pools at public kindergartens, elementary schools, junior high schools and high schools in Fukushima can't be drained. Most of these pools are located in eastern parts of the prefecture near the damaged nuclear plant or in central Fukushima Prefecture. One-third of the pools are designed to drain their water into sewage systems, while the rest have to drain the water directly into agricultural waterways or rivers.

The Education Ministry's School Health Education Division says there are no legal guidelines for draining pool water. The ministry instructed the prefectural education board to obtain consent from farming and other related organizations when draining pool water into rivers and agricultural waterways, and the board passed the information on to schools in May, but farmers have been reluctant to allow schools to drain pool water into waterways. There are also many cases in which schools have the option of draining water into sewage lines, but they have not done so out of consideration for local residents.

At Fukushima Daiichi Elementary School in the city of Fukushima, the bottom of the school pool is darkened with dust contaminated with radioactive materials, and algae has turned the water green.

"We're concerned about health, too, so we want to drain the pools quickly, but we don't know the extent of contamination of the water and the sludge, and we can't cause trouble for people around the school," the school's principal commented.

In the cities of Date and Minamisoma, decontamination work using zeolite and other agents that can absorb radioactive materials has been carried out, but the cost of such work is said to reach several million yen per pool.

Since May, the prefectural board of education has asked the Education Ministry to present standards and methods for draining pool water, but ministry officials have merely responded that they will consult with related government ministries and agencies, and have provided no response.

A representative of the ministry's School Health Education Division commented, "Creating standards is difficult, and there is no option but to have schools and other related parties come to an agreement."

When asked about the radiation, a representative of the Ministry of Economy, Trade and Industry's Nuclear and Industrial Safety Agency said, "We are not considering any particular response for pools alone." Meanwhile, a representative of the Ministry of Land, Infrastructure and Transport, which is in charge of sewage, said, "There is no problem with draining water into sewage lines, but when it comes to making arrangements with locals, that's out of our jurisdiction."

Muneyuki Shindo, a former Chiba University professor, said **guidelines on decontamination should be provided.**

"If jurisdiction over different parts of the work is divided, then officials should measure the concentration in accordance with clear instructions from the Cabinet, and present methods of

decontamination," he said. "This is a typical scenario highlighting the government's lack of ability to make decisions and get things done."

Kyoto scraps plan to use firewood from disaster area for bonfire over radiation concerns

This photo shows pieces of firewood in which radioactive cesium is detected on Aug. 11, 2011, after being delivered to the Kyoto Municipal Government from Rikuzentakata, Iwate Prefecture. (Mainichi)

KYOTO -- The Kyoto Municipal Government said on Aug. 12 that it would scrap its plan to use firewood from pine trees knocked down by the March 11 tsunami for the city's iconic bonfire festival after it detected radioactive cesium in pieces of the firewood sent from a disaster-stricken city in northeastern Japan.

One of five local groups tasked with preserving the "Gozan no Okuribi" in which five giant bonfires are lit on mountains surrounding the city of Kyoto had originally planned to use the firewood from Rikuzentakata, Iwate Prefecture, for the ancient festival on Aug. 16, the culmination of the Bon festival. But the group decided to abandon the plans after receiving a barrage of concerns over radiation contamination. The Kyoto Municipal Government was then bombarded with criticism that the cancellation of the plans could fan harmful rumors about radiation threats. Therefore, Kyoto Mayor Daisaku Kadokawa asked the preservation groups to get other batches of about 500 pieces of firewood from Rikuzentakata and use them for the festival. The groups had accepted the request.

According to the Kyoto Municipal Government, **about 1,130 becquerels of cesium per kilogram was detected in the outer layers of the new firewood from pine trees knocked down by the tsunami.** No cesium was detected in the trunks of the firewood. **There are no legal limits on burning radioactive substances outdoors.** When the Kyoto Municipal Government asked experts, they replied, "Because there are no standards set by the government, we cannot say it is safe."

The 500 pieces of firewood were brought to Kyoto on a truck from Rikuzentakata on Aug. 11 before being sent to Shimazu Techno Research, an inspection firm in the city. The city received a report from

the inspection company on the afternoon of Aug. 12. Fragmented outer layers of all the 500 pieces of firewood, weighing about 1 kilogram, went through inspections.

City mayor Kadokawa told a news conference, "I want to offer my heart-felt apology to the Rikuzentakata city and everyone affected by the Great East Japan Earthquake." He added, "We will cancel the event because the assumption that radioactive substances have not been detected cannot hold water. We did not base our decision on whether the firewood from the disaster-stricken area is safe or not." He also said the city government did not discuss whether to burn only the trunks of the firewood for the festival.

The firewood is being kept in a storage facility run by a private company in Kyoto. But no decision has been made on what to do with the firewood. Mayor Kadokawa said, "We want to deal with the issue without returning the wood."

Futoshi Toba, the mayor of Rikuzentakata, said on Aug. 12, "The good intentions of the people concerned ended up coming to something like this, causing trouble to our citizens." On the way the Kyoto Municipal Government handled the case, Toba said, "Harmful rumors are spreading and causing trouble to other disaster-stricken areas and the people of Kyoto. I wished (the Kyoto Municipal Government) had handled it more carefully." Kyoto Mayor Kadokawa expressed his intention to visit Rikuzentakata, but the Rikuzentakata Municipal Government told him, "Thank you for your concern, but this is quite enough for us."

On the levels of radiation detected in the firewood, experts say they are far from dangerous levels. Otsura Niwa, a main commission member of the International Commission on Radiological Protection (ICRP), said, "Even if you ate 1 kilogram of the outer layers of the firewood and absorbed them in your body, it (the effect of radiation) is of no significance." He added, "The decision to seek unnecessary pure firewood tramples upon the sentiments of the people of the disaster-stricken area."

Ikuo Anzai, professor emeritus in radiation protection at Ritsumeikan University, said, "'Gozan no Okuribi' has characteristics of rituals. That may be the reason why radiation was taken as something unclean. This is not a scientific issue but a cultural issue. It should be solved culturally. Memorial ceremonies should be held for the victims (of the disasters)."

Govt to compile decontamination plan

The Japanese government says it will prepare by the end of August a basic plan for decontaminating areas near the stricken Fukushima Daiichi nuclear plant.

Prime Minister Naoto Kan on Monday asked the nuclear crisis minister, Goshi Hosono, to begin compiling the steps that must be taken.

The government is planning to lift the designation soon of the zone extending from 20 to 30 kilometers away from the nuclear plant where residents have been told they must evacuate in the event of another emergency.

The measure would allow the return of some people who have left voluntarily, although worries about radiation persist among the affected communities.

The government plans to ease such concerns by adding more manpower to a taskforce in charge of decontamination.

The basic plan could also call for closer analyses of contaminated crops and plants to find out whether the radiation came from the air or soil.

Tuesday, August 16, 2011 09:46 +0900 (JST)

TEPCO tests Japan-made decontamination unit

Tokyo Electric Power Company is conducting a trial run of a Japan-built water decontamination unit at its troubled Fukushima Daiichi nuclear power plant.

TEPCO started testing the performance of the new equipment shortly past noon on Tuesday.

The domestic-made unit uses 14 cylindrical tanks, each 3.5 meters high and 1.4 meters across, that contain minerals to absorb radioactive materials.

The utility plans to continue the trial until Wednesday night, before starting full-fledged operations.

Since late June, TEPCO has been decontaminating highly radioactive wastewater from the reactors and then injecting the cleaned water back into the reactors to cool them.

But the decontamination system --- the key part of the water circulation process --- has been plagued with trouble and its foreign-made components have repeatedly stopped operating. TEPCO says it has been running at 66 percent of capacity, failing to meet the initial target of 90 percent.

The power company hopes the new, Japan-built decontamination unit will help achieve stable circulation for cooling.

TEPCO to use desalinating devices in pools

Tokyo Electric Power Company is planning to use devices to remove salt from spent nuclear fuel pools at the Fukushima Daiichi nuclear power plant.

The operator fears that **saltwater used to cool reactors 2 - 4 after the March 11 disaster could corrode stainless steel pipes and pool walls.**

The new devices will arrive on 5 trucks and use special membranes and electricity to desalinate water.

TEPCO plans to first use the machinery by the end of this week **at the number 4 reactor, which contains**

the most spent fuel. The concentration of salt is expected to be reduced by 96 percent in 2 months.

It will then follow up in reactors 2 and 3.

Water temperatures at all 4 reactor pools have been relatively stable since the installation of a circulating cooling system was completed on August 10th.

Reactor facilities to purify wastewater have all been equipped with desalinating filters.

Another device that uses the mineral, zeolite, to remove radioactive substances from circulating water has been installed in the cooling system of the number 2 to 4 reactors.

Through such measures, TEPCO hopes to stably operate the plant over the long-term until all the spent fuel is removed.

Tuesday, August 16, 2011 12:23 +0900 (JST)

Radioactive sludge piling up

Radioactive sludge from sewage facilities across Japan has been piling up in storage facilities, despite the government's plan to bury it.

NHK asked local governments in 17 prefectures in northeastern to central Japan how they are coping with sludge that's been contaminated by radioactive material from the Fukushima Daiichi nuclear plant.

Contaminated sludge from sewage facilities now totals more than 54,400 tons. 75 percent of it contains less than 8,000 becquerels per kilogram of radioactive cesium, the government-set limit for disposal by burial.

Despite this, some 27,700 tons of sludge --- 51 percent of the total --- remains in storage at water treatment plants.

Local governments say some burial projects have been rejected by residents near proposed sites.

In addition, 7 storage facilities in 4 prefectures have had to set up "no entry zones" where radiation levels have gotten too high.

Tuesday, August 16, 2011 22:51 +0900 (JST)

Probe finds TEPCO failed to predict hydrogen explosion at Fukushima nuclear plant

The damaged No. 1 reactor building, center left, at the Fukushima No. 1 Nuclear Power Plant is pictured on March 12. (Mainichi)

The operator of the tsunami-hit Fukushima No. 1 Nuclear Power Plant failed to predict the hydrogen explosion that occurred on March 12 following the disaster, sources involved in the investigation into the crisis said.

"Nobody was able to predict the explosion," an employee at Tokyo Electric Power Co. (TEPCO) was quoted as telling members of the government's fact-finding panel on the Fukushima nuclear crisis.

"We made a serious mistake as we failed to grasp important information on the power station," plant manager Masao Yoshida was quoted as telling the panel.

The investigation has also revealed that TEPCO did not prepare an instruction manual on procedures for venting to protect reactors' containment vessels when external power sources are lost.

As part of its investigation into the crisis, the fact-finding panel has questioned Yoshida and other TEPCO employees as well as officials with government regulators. It will closely examine the answers as well as data on the accident in order to get to the bottom of the crisis.

The hydrogen explosion occurred at the plant's No. 1 reactor at 3:36 p.m. on March 12, the day after the Great East Japan Earthquake and tsunami hit the plant. The blast blew off the upper part of the building housing the reactor.

Experts suspect that the hydrogen was generated after zirconium contained in fuel rods was heated and reacted with water.

TEPCO officials told the fact-finding panel that workers had never imagined that hydrogen would fill the reactor building and eventually explode because they were preoccupied with checking the conditions of the reactor and its containment vessel.

Because the plant had no instruction manual on venting, workers were forced to consider a procedure for venting by closely examining the blueprint of the reactor.

Since all the external power sources had been lost, workers at the plant procured batteries and other equipment to secure power sources. However, due to insufficient communications between workers on

the types of devices that were needed, various machines were brought into the plant, forcing workers to take time to select usable devices from among them.

Moreover, some of the devices were mistakenly delivered to the Fukushima No. 2 Nuclear Power Plant -- situated about 10 kilometers south of the crippled No. 1 plant -- and the J-Village soccer training ground, about 20 kilometers south of the No. 1 plant, where plant workers were staying, forcing workers to visit these facilities to pick up the devices.

"The TEPCO headquarters didn't extend sufficient support to us," one of the employees was quoted as lamenting during the questioning.

Furthermore, the panel has discovered that Yoshida and other top officials with the plant failed to notice the isolation condenser (IC), necessary to cool down the core of the No. 1 reactor in case of emergency, had stopped working, and considered countermeasures on the assumption that the IC was functioning properly.

Workers rush to decontaminate schools in Fukushima Pref. city before start of term

Workers spray and scrub the floors of Kashiwa Elementary School in Minamisoma, Fukushima Prefecture, on Aug. 16. (Mainichi)

MINAMISOMA, Fukushima -- Workers are rushing to finish decontaminating a elementary school here just north of the nuclear crisis exclusion zone in time for the beginning of the new term on Aug. 25.

"The schedule is pretty harsh, but we'd like to finish on time somehow," one worker at Kashiwa Elementary School told the Mainichi. Similar operations have been going on at municipal schools, kindergartens and nursery schools since Aug. 1, while the children are on summer break.

The workers are hosing down and scrubbing the walls and floors at the school and using heavy machinery to remove the top soil on the playground and flower beds to rid the building and grounds of radioactive substances. The top soil is being deposited in a 30-meter-long, 2-meter-deep pit for later burial.

Much of Minamisoma lies within a 30-kilometer radius of the crisis-stricken Fukushima No. 1 Nuclear Power Plant covered by exclusion and evacuation standby zones. Decontamination was ordered for all the city's schools outside that area, and similar operations are scheduled for the schools in the evacuation standby zone, between 20 and 30 kilometers from the plant, as early as the end of August.

(Mainichi Japan) August 17, 2011

Excessive levels of radioactive cesium found 100 km from plant

FUKUSHIMA (Kyodo) -- Excessive levels of radioactive cesium were found in sludge in a ditch at a district court branch in Fukushima Prefecture, about 100 kilometers west of the crippled Fukushima No. 1 nuclear power plant, the court said Tuesday.

The isotope in the sludge, sampled from a ditch at the Fukushima District Court's Aizuwakamatsu branch, measured about 186,000 becquerels per kilogram, the court said, adding it plans to remove the sludge after consulting with local governments.

Under government standards, sludge can be used in a landfill as long as the radioactive cesium contained in it measures 8,000 becquerels per kilogram or lower.

The court has barred entry within 1 meter of the area where the sludge was sampled and another where radiation levels were higher than other locations on the premises, but that has not disrupted court business, it said.

The nuclear power plant, operated by Tokyo Electric Power Co., spewed massive amounts of radioactive materials into the air and ocean after a series of explosions that followed the March earthquake and tsunami.

(Mainichi Japan) August 17, 2011

Cooling stoppage unknown to plant chief

Government investigators have found that the chief of the Fukushima Daiichi nuclear power plant did not know that a backup cooling system for one of the plant's reactors was manually shut down on March 11th, the day of the quake and tsunami.

The investigators learned that Masao Yoshida was unaware that a worker stopped the system to prevent it from being damaged. The worker told the investigators that the system appeared to be operating at boiling temperature but was not producing steam.

Yoshida reportedly said it was a major error that he and other leaders did not immediately know such important safety information.

The plant's operator, TEPCO, says a fuel meltdown took place at the reactor 5 hours after the quake, generating large amounts of hydrogen that caused an explosion on the following day.

University of Tokyo Professor Koji Okamoto said the reactor lost all cooling functions due to the stoppage, and that the reactor's core should have been cooled by all possible means.

Okamoto said the failure of communication may have worsened the situation by delaying orders for water injections and government evacuations of nearby residents.

Wednesday, August 17, 2011 22:20 +0900 (JST)

Radioactivity down to one-fifth of July levels

The Japanese government and Tokyo Electric Power Company say the amount of radioactive material being emitted from the Fukushima Daiichi nuclear plant has dropped to one-fifth that of a month ago.

The government and TEPCO said on Wednesday that maximum radiation levels around the plant during the past 2 weeks were 200 million becquerels per hour.

This is one-fifth the levels detected in July, and one-10 millionth the levels in mid-March, shortly after the troubles began at the plant.

The state minister in charge of the nuclear crisis, Goshi Hosono, said the maximum reading of **200 million becquerels is just an estimate because the exact emission levels cannot be accurately measured.**

He pledged to seek methods for making precise measurements and for containing radioactivity inside the plant.

The government and TEPCO said there is no major change in their timetable for bringing the plant under control, and that their goal continues to be to achieve cold shutdown of the reactors while processing contaminated wastewater and reducing radioactive emissions.

The government said it will draw up a plan for decontaminating the current evacuation zone by the end of August, and it will launch a model decontamination project early next month.

Experts say that before the government allows residents to return to the evacuation zone, it will be necessary to prevent new leakage of radioactive material, as well as decontaminate material already leaked and dispose of mud and sludge generated by the decontamination process.

Wednesday, August 17, 2011 22:23 +0900 (JST)

Head of Tokyo University Radioisotope Center calls for speedy decontamination

"Seventy-thousand people are wandering about after evacuating from their homes. What on earth is the Diet doing?!" Tatsuhiko Kodama, 58, head of the University of Tokyo Radioisotope Center, stood before the Committee on Health, Labor and Welfare of the House of Representatives at the end of July and angrily berated the government for its slack radiation policies in a speech that has attracted a strong response. Dr. Kodama is a specialist in cancer treatment, but is also known as an "action-oriented researcher" who is engaged in decontamination operations in Fukushima Prefecture's Minamisoma. In an interview with the Mainichi, Dr. Kodama talked about what he thinks the government should be doing.

Question: You have pointed out that existing methods are inadequate to deal with the present situation. Can you explain?

Answer: By our estimates, the radioactive material released from Fukushima No. 1 Nuclear Power Plant, in uranium equivalents, amounts to 20 times the radiation released by the atomic bombing of Hiroshima. What's more, the radiation will decrease at a much slower rate than after the A-bomb. When the amount of radiation is small, it's enough to consider on-the-spot radiation. But when the total volume is huge, we have to think about how the particles will disperse. This happens in a non-linear manner, which is very difficult to calculate scientifically, because concentration is apt to occur in unpredictable locations. This will keep happening, such as when feed-hay for cattle was contaminated by cesium, and when contamination was found in tea and leaf mulch.

Q: How should we deal with the contamination of food?

A: With state-of-the-art technology, we can use imaging detectors to assess food contamination in large batches. Japan leads the world in this kind of technology. Manufacturers say they can make these machines in three months. But the government has been doing nothing. Rice and seafood will soon be a problem. To maintain food safety, we urgently need to develop state-of-the-art measurement devices, get them out to every municipality and set up assembly-line-type operations to detect contamination.

Q: Families with children are worried about radiation around their homes and schools. What should they do?

A: I suggest that "on-the-spot detection squads" and "call centers" be set up in every municipality of the disaster area. When a call comes in, 20 or 30 minutes could be spent going around with the caller and checking out homes or wherever it is kids are spending their time. Locations with high-level radiation should be decontaminated at once. In Minamisoma, many families have evacuated their children and have broken their families up to do so, but some areas near the coast have relatively low radiation and are safe for children. We should be aware of these facts, and on-the-spot teams should be there to help with emergency decontamination.

Q: Different experts have different opinions about low-dose internal radiation exposure, and this is adding to the confusion. Why is this so?

A: Cancer is caused by multiple gene mutations over a period of several decades. After Chernobyl, it took 20 years to statistically confirm the increased incidence of thyroid cancer in children. We won't know until much later, so rather than deciding now if it's safe or not, the important thing is to devote ourselves to "measurement and decontamination."

Q: You said in your Diet speech that operations should be divided into two types: localized emergency decontamination and the permanent decontamination of whole regions. Can you elaborate?

A: To make the environment safe for children, we are conducting emergency decontamination of places like kindergartens. But the water we use to wash out gutters will remain in the environment, and there's a limit to how far we can bring down radiation levels with emergency measures. Permanent decontamination will provide a fundamental solution to these problems, but it will be an immense project that calls for the creation of a "decontamination research center" of some kind to assess the problem as well as the cost. Japan will really have to throw itself into the project and bring its finest decontamination technology to Fukushima. Decontamination methods should be discussed with local residents. And we must not let it become a public works project linked to vested interests. Japan's financial situation doesn't allow us the luxury of spending trillions of yen and then saying: "Sorry, we couldn't decontaminate it any further."

Q: The government is moving much too slowly, considering that this is a real emergency. What do you think?

A: After decontaminating, we can't just leave the contaminated earth lying around, so we're packing it into drums and bringing it back to Tokyo, which is actually illegal. This is because existing laws don't provide for situations of this kind. How can we protect our children when our hands are tied by old laws? I asked politicians to enact new laws, so that we can clean up some of the radiation they've unleashed. I mean, what have they been doing all these four months? Food contamination tests, on-the-spot decontamination squads and call centers, emergency decontamination, permanent decontamination -- these are the four things I'm asking for.

Dr. Kodama completed Medical School at the University of Tokyo and became an internist doing both clinical and research work. Since 1996, he has been a professor of Systems Biology and Medicine at the University of Tokyo's Research Center for Advanced Science and Technology, and in 2011 took on the additional job of head of the university's Radioisotope Research Center.

Because Dr. Kodama is working to develop cancer treatment methods using isotopes, he is well informed about the problems of internal radiation exposure. After the nuclear power plant incident, he has been visiting the city of Minamisoma in Fukushima Prefecture every weekend to conduct radiation measurements and decontamination at locations like kindergartens.

On July 27, Dr. Kodama gave testimony before the Committee for Health, Labor and Welfare of the Lower House of the Diet. He strongly criticized the negligence of the government in not channeling its energies into radiation tests for food when fears about food contamination are so widespread, and in not working to enact new laws to better protect children. "Unless the government commits itself to reducing radioactive materials, the Japanese people will not trust what it says about safety." Dr.

Kodama also proposed some specific measures. The hearing has been posted on numerous video-sharing websites and is attracting a large audience. (By Yuri Aono, Editorial Writer)

(Mainichi Japan) August 17, 2011

Questions remain over risks despite resumption of operations at Hokkaido nuke plant

Questions remain about the adequacy of the risk assessment of the No. 3 reactor at Hokkaido Electric Power Co.'s Tomari Nuclear Power Plant, whose commercial operations resumed after the Hokkaido Gov. Harumi Takahashi gave the green light on Aug. 17.

In a rare move, the reactor had been in a so-called "adjustment operation" -- part of the last stage of regular inspections -- for more than five months.

The government requires power suppliers to conduct a primary assessment of the stress tests on reactors as a precondition for reactivating nuclear reactors undergoing regular inspections.

Nuclear reactors in full operation are subject to a secondary assessment. Tomari's No. 3 reactor was actually generating electric power at full capacity even though it was undergoing regular inspections. Therefore, the utility as well as government regulators made a difficult judgment when they decided to shift to commercial operations.

However, the essential question is not whether the reactor should be subject to a primary or secondary assessment. Keeping in mind a lesson learned from the ongoing crisis at the tsunami-hit Fukushima No. 1 Nuclear Power Plant, the operator of the Tomari plant as well as government regulators should have conducted their best risk assessment and provided a sufficient explanation to the local community and the general public. They then should have decided whether to resume commercial operations at the reactor.

Nevertheless, confusion over procedures for resuming commercial operations at the Tomari plant's No. 3 reactor has shown that the central and local governments and the utility have decided to resume commercial operations based not on the results of their best risk assessment.

Rather, it has given the public the impression that the national and local governments' response was politically motivated, pushing aside discussions on the safety of the reactor. Such a response can neither ensure the security of local residents nor gain confidence from the public.

Safety measures that utilities have implemented at their respective nuclear power stations following the Fukushima accident are merely stopgap measures. It is also the case with Hokkaido Electric Power's deployment of vehicles equipped with power generators, emergency pumps and heavy machine tools in case of a natural disaster to remove rubble at the Tomari plant, as well as its establishment of procedures for releasing hydrogen from its reactor buildings.

Since concerns about risks involving the Tomari power plant's No. 3 reactor are far from being dispelled, Hokkaido Electric Power must not be relieved simply because commercial operations have been resumed at the reactor. Rather, the utility should regard the green light for its commercial operations as a "provisional license," and proactively go ahead with its safety assessment of the reactor and promptly release the results of such an assessment.

The national government attempted to settle the dispute over whether to resume operations at the reactor by subjecting the reactor to double checks by the Nuclear and Industrial Safety Agency (NISA) and the Nuclear Safety Commission of Japan (NSC). However, the NSC would not make its own judgment on the reactor's safety on the grounds that it neither is legally authorized to express opinions on such a matter nor has it been asked by the central government's headquarters to do so.

Such discord between the government's headquarters, NISA and NSC, which has been ongoing for years, only damages the public's confidence in the safety of nuclear power stations.

Following the Fukushima accident, the public's confidence in the government's nuclear power safety regulators and its safety standards has been lost. Each of these relevant entities must do their best to ensure the safety of nuclear power plants until the government sets up a new regulatory body and works out new safety standards.

This is the first time since the Fukushima nuclear accident that commercial operations at a nuclear power plant, which had been suspended for scheduled inspections, have been resumed. However, it is wrong to believe that it will give momentum to attempts to resume operations at other nuclear reactors suspended for inspections. A decision on whether to reactivate nuclear reactors or whether to continue operations should be made depending on the risk assessment of each nuclear reactor. Power companies are urged to strictly assess risks at their nuclear plants.

Nuclear safety agency advised Niigata gov't not to hold joint quake, nuke disaster drill

The Nuclear and Industrial Safety Agency (NISA) discouraged the Niigata Prefectural Government from holding a disaster drill envisaging the simultaneous occurrence of an earthquake and nuclear disaster, it has been learned.

A study by a government panel investigating the causes of the nuclear accident at the Fukushima No. 1 Nuclear Power Plant found that **NISA had advised the Niigata Prefectural Government not to hold the twin-disaster drill in 2010, saying it could cause fear and invite misunderstanding among residents.**

As a result, the Niigata Prefectural Government dropped the initial plan and instead conducted a drill envisaging a snow and nuclear disaster.

The revelation indicates that NISA forced on the prefectural government the myth that nuclear power plants were safe, and the government panel is poised to investigate if NISA's stance could have added to damage in the Fukushima accident.

According to internal documents obtained by the Mainichi Shimbun, the panel's damage limitation measures verification team started interviewing concerned parties on July 14 over the Fukushima

nuclear crisis. As of Aug. 9, the panel had questioned some 60 officials from NISA, the Cabinet Secretariat and the Nuclear Safety Commission of Japan. The panel is further to question a total of around 200 officials.

In the wake of an accident at Tokyo Electric Power Co. (TEPCO)'s Kashiwazaki-Kariwa Nuclear Power Plant in Niigata Prefecture in 2007, which was triggered by the Niigata-ken Chuetsu-oki Earthquake, the Niigata Prefectural Government started considering in May 2010 a disaster drill assuming the simultaneous occurrence of a quake and nuclear disaster.

NISA, however, told the prefectural government, "Conducting a multiple disaster drill presupposing an earthquake measuring lower 5 on the Japanese seismic scale of 7 and a nuclear disaster could cause fear and invite misunderstanding among residents."

In response, the prefectural government conducted a drill for a simultaneous snow and nuclear disaster in November 2010.

Furthermore, NISA underestimated the risk of a major natural disaster and a nuclear disaster occurring simultaneously or almost simultaneously in a report submitted to a subcommittee of the Advisory Committee for Natural Resources and Energy, a panel to the economy, trade and industry minister, in April 2009.

In the draft report filed by NISA on points to consider in preparing manuals for nuclear disaster prevention, the agency stated that "sufficient measures have been taken (at nuclear power plants) to ensure safety even in case of the most severe earthquake possible." The report also asserted that "the probability of a nuclear disaster actually occurring as a result of a major natural disaster is extremely low."

The revelation about the Niigata drill case surfaced while the fact-finding panel was investigating emergency drills that had taken place in Fukushima Prefecture before the nuclear accident. The panel is continuing to probe the case to see if NISA's disregard of a possible quake-nuclear disaster could have led to questionable advice to the Niigata Prefectural Government.

(Mainichi Japan) August 18, 2011

Fukushima plant leaking less radioactive material: TEPCO

TOKYO (Kyodo) -- Tokyo Electric Power Co. said Wednesday the amount of radioactive substances leaking from the crippled reactors at the Fukushima Daiichi nuclear power plant has declined over the past month, but stopped short of declaring that one of the conditions to achieve a cold shutdown has been cleared.

The data was included in the latest version of a road map to contain the nuclear crisis. It left unchanged the time frame to stabilize the reactors by January and highlighted a need to train and deploy experts on radiation dose management.

According to the plant operator TEPCO, the amount of radioactive substances leaking from the Nos. 1, 2 and 3 reactors dropped to a maximum 200 million becquerels per hour, from 1 billion becquerels per hour a month earlier.

The figure means that a person could be exposed to up to 0.4 millisievert when standing around the plant for one year, below the government-set reference limit of 1 millisievert per year.

The public exposure dose, in addition to the temperature of the reactors, is a key factor for judging whether the crisis-hit plant has achieved a state of cold shutdown. But TEPCO and government nuclear safety agency officials said the accuracy of the estimates of exposure dose is "rough."

At a joint press conference with TEPCO, nuclear disaster minister Goshi Hosono said improving the functioning of water decontamination facilities at the plant is a "major challenge" toward achieving a cold shutdown.

Restoration efforts moved onto the "step 2" phase of the road map in July, after TEPCO and the government declared the "step 1" goals of stably cooling the damaged reactors and reducing the radiation dose around the site had been achieved.

Completing the step 2 phase was estimated to take a further three to six months.

A senior government official who attended the press conference did not narrow down the time range, leaving uncertain when residents of areas around the plant can put their lives back in order.

Hit by a magnitude-9.0 earthquake and massive tsunami on March 11, the Fukushima nuclear plant lost nearly all its power sources, and consequently the ability to cool the reactors and spent fuel pools at the Nos. 1 to 4 units. The buildup of heat and gas inside subsequently led to a series of explosions which badly damaged three of the reactors.

TEPCO has created a new system that removes radioactive substances from polluted water accumulating inside the plant and recycles the decontaminated water to cool the crippled reactors. But the water processing system has been plagued with problems and its operating rate has averaged just 69 percent since the system began operating in June, according to TEPCO.

As radioactive polluted water is created by injecting water into the damaged reactors, it is important to reduce the amount of water accumulating within the plant so that it does not overflow, Hosono said.

Hosono also said the government plans to start from September experimental projects on cleaning the radiation-contaminated areas outside the plant before implementing full-scale decontamination such as within a 20-kilometer radius of the plant designated as a no-entry zone.

During the press conference, TEPCO showed a video that delivered a message from Masao Yoshida, head of the Fukushima power plant, who apologized for causing great inconvenience amid the world's worst nuclear crisis since the 1986 Chernobyl disaster.

It was the first time that TEPCO made Yoshida's voice public since the nuclear crisis. In the video, available on TEPCO's website, he expressed gratitude for "warm" messages of support received from in and outside the country.

Yoshida drew media attention over his decision to continue injecting seawater into one of the troubled reactors in the early days of the crisis as an emergency step, despite an order to suspend the injection, at one point suspected to be coming from Prime Minister Naoto Kan.

The company issued a warning to him for falsely reporting the facts, although his decision was widely seen to be appropriate.

Iran, Russia to seek resumption of nuclear talks

The foreign ministers of Iran and Russia have agreed to seek a resumption of talks with major Western countries based on a Russian proposal to reach a breakthrough in the standoff over Iran's nuclear program.

Iran's Ali Akbar Salehi met Russia's Sergei Lavrov in Moscow on Wednesday.

They discussed a Russian proposal for a phased easing of sanctions in exchange for Iran addressing international concerns over its nuclear program.

At a news conference after the meeting, Salehi said Iran is positive about the proposal and has agreed to begin talks on the country's nuclear program with UN Security Council permanent members and Germany.

Lavrov said he hopes the proposal will help things move forward and that negotiations will resume soon.

But the Iranian foreign minister added his country will not accept any kind of pressure, apparently in reference to Western nations.

Russia appears ready to continue mediating between Iran and the global powers. But Iran insists that its nuclear program is for peaceful purposes and rejects halting its uranium enrichment activity.

Thursday, August 18, 2011 09:08 +0900 (JST)

Agency didn't think to tell neighboring countries radioactive water was released into sea

Nobody in the Nuclear and Industrial Safety Agency (NISA) thought of notifying the governments of neighboring countries before water containing low levels of radiation at the tsunami-hit nuclear power plant was released into the sea, it has been learned.

The Foreign Ministry also learned of the measure only after being alerted by an official assigned to the Tokyo Electric Power Co. (TEPCO) accident task force, who happened to see a TEPCO document.

The revelations illustrate NISA's lack of a sense of crisis and problems involving the communication system between nuclear power plant operators and government regulators on crucial information.

The government's panel investigating the crisis at the Fukushima No. 1 Nuclear Power Plant found out about the lack of communication after questioning officials with NISA, the Nuclear Safety Commission of Japan (NSC) and others involved.

According to sources familiar with the investigation, TEPCO noticed in late March this year that water contaminated with high levels of radiation had accumulated in the basements of buildings that house turbines for the No. 1 to 3 reactors at the crippled power plant.

On April 1, a task force comprised of officials with TEPCO and other entities considered a plan to release water containing low levels of radiation from the plant's intensive waste disposal facility into the sea to make room for water contaminated with high levels of radiation at the turbine buildings.

The task force initially abandoned the plan after some of its members voiced stiff opposition to it.

However, after low-level radioactive water was transferred to the No. 4 reactor's turbine building, workers noticed on the morning of April 4 that the water level in the No. 3 turbine building had also risen. Workers stopped sending water to the No. 4 turbine building after suspecting that the two turbine buildings were connected underground.

The finding prompted TEPCO, NISA and the NSC secretariat to prepare to release the low-level radioactive water into the sea.

After gaining approval from Prime Minister Naoto Kan and advice from NSC, NISA notified TEPCO later in the day that it was unavoidable to release radioactive water into the sea.

The chief Cabinet secretary announced the decision at a news conference at 4 p.m. on that day. TEPCO began releasing contaminated water shortly after 7 p.m.

However, none of the officials with NISA, who were involved in the procedure for releasing radioactive water into the sea, thought to notify the governments of neighboring countries in advance, even though the agency is supposed to notify the governments of foreign countries of any nuclear accident in Japan, the sources said.

An official with NISA's international affairs division, who happened to see the chief Cabinet secretary's news conference on TV, notified the International Atomic Energy Agency by e-mail only one hour before the water was released.

The Foreign Ministry also learned that TEPCO was releasing radioactive water into the sea after being alerted by a junior official assigned to TEPCO's accident task force, who happened to see a draft of the utility's public relations document on the measure.

The contaminated water was released between April 4 and 10, sparking criticism from neighboring countries as well as local governments near the plant that they had not been notified in advance.

Map shows spot with high level of radiation near Fukushima plant

TOKYO (Kyodo) -- The science ministry published a map on Friday on cumulative radiation estimates five months after the Fukushima Daiichi nuclear power plant was crippled in March, showing a nearby town with a high level of radiation.

In giving specific estimates for 50 locations in the no-entry zone for the first time, the ministry said cumulative radiation of 278 millisieverts was estimated for a location in the town of **Okuma, 3 kilometers southwest of the troubled plant.**

The annual radiation exposure limit for ordinary people is 1 millisievert. The government has urged people living in areas around the plant where annual exposure is likely to exceed 20 millisieverts to evacuate.

The estimates for the five-month period were varied, with several millisieverts of cumulative radiation for some locations even within the no-entry zone.

The data would therefore be used as a guide when considering the lifting of the entry ban in the future, according to the Ministry of Education, Culture, Sports, Science and Technology, which oversees the readings.

The government is also considering allowing evacuees from areas within a 3-km radius of the plant to return home temporarily.

Cumulative radiation over the one-year period from the start of the disaster is projected to reach between several millisieverts and over 500 millisieverts at the 50 locations within the no-entry zone.

Outside the exclusion zone, cumulative radiation in the town of Namie, 22 km northwest of the plant, was estimated at 115 millisieverts over the five-month period, the highest among locations outside the zone and equivalent to 229 millisieverts over a 12-month period.

The cumulative radiation map is based on readings taken at 4,283 locations, with a focus on Fukushima Prefecture.

(Mainichi Japan) August 20, 2011

Cattle shipment ban lifted in Miyagi

The Japanese government has decided to allow Miyagi Prefecture to resume shipments of all cattle that clear radiation tests.

Chief Cabinet Secretary Yukio Edano told reporters on Friday that only properly managed cattle whose meat is safe to eat will be allowed to reach markets.

Edano said Miyagi Prefecture has put in place a system to prevent shipments of cattle whose levels of

radioactive cesium exceed the government's safety limit.

The restrictions were imposed after excess levels of cesium were detected in beef from cows fed on highly contaminated rice straw in the wake of the Fukushima Daiichi nuclear plant accident.

Before shipments are resumed, Miyagi will test all cattle that ate the contaminated feed. Blanket testing will also be conducted at farms whose straw feed has yet to be inspected. Other farms are required to test only the first animals they intend to ship out.

A ban on shipments is still in place in 3 other prefectures. Among them, Fukushima was due to see the measure lifted on Friday. But the government put off the move after unsafe levels of radioactive cesium were found in beef from a Fukushima cow not fed contaminated straw.

In the 2 other prefectures of Iwate and Tochigi, the government says shipments could resume once local authorities introduce safety controls similar to those adopted in Miyagi.

Friday, August 19, 2011 23:55 +0900 (JST)

Radioactive cesium detected in boar meat in Miyagi Pref.

SENDAI (Kyodo) -- Radioactive cesium at a level over four times the government-set safety limit has been detected in the meat of a wild boar captured in Kakuda city, Miyagi Prefecture, the prefectural government said Friday.

It is the first time that radioactive contamination exceeding the safety limit was found in a wild animal or bird in the northeastern Japanese prefecture, local officials said, adding **they will ask people in the prefecture not to eat meat of wild animals and birds for the time being.**

The meat of the boar, which local hunters caught in the mountains in Kakuda on Aug. 7 in response to a request by the city government to exterminate it, measured 2,200 becquerels of cesium per kilogram. The central government's provisional safety limit is 500 becquerels per kg.

Miyagi Prefecture borders Fukushima Prefecture, where the badly damaged Fukushima Daiichi nuclear power plant is located.

(Mainichi Japan) August 20, 2011

New office to address radioactive contamination

Japan's minister in charge of nuclear crisis has said that the government will establish a task force next week to address radioactive contamination in areas around the Fukushima Daiichi nuclear power plant.

Goshi Hosono made the comment at a meeting with Fukushima Governor Yuhei Sato on Saturday.

Hosono added that the central government will set up a team in Fukushima to facilitate radioactive

decontamination work.

Hosono said the government will allocate budgets to deal with the ongoing nuclear disaster as it bears heavy responsibility for the accident at the Fukushima plant.

Hosono said removal of radioactive substances is becoming the most important issue.

Saturday, August 20, 2011 14:46 +0900 (JST)

More contaminated cows from Fukushima

Beef from 5 more cows from a Fukushima farm has been found to be contaminated with radioactive cesium in excess of the government-set safety limit.

The revelation by Fukushima Prefecture on Saturday followed reports one day earlier that beef from 4 cows from the same farm had been found to contain radioactive cesium twice the safety standard.

This prompted the central government on Friday to put off lifting a shipment ban on Fukushima beef.

Fukushima authorities say the 9 cows were among a total of over 200 head of cattle shipped from the farm and slaughtered at a facility in Yokohama city between the March 11th nuclear accident and April. The meat of the 9 had been stored by a food producer.

The farm reportedly denied giving the cows rice straw suspected of being contaminated with radioactive cesium.

It stated it fed them imported hay that had been stored at another farm.

The local authorities are investigating to find out how the beef came to be contaminated.

Sunday, August 21, 2011 08:58 +0900 (JST)

Fukushima officials worry new discovery of radioactive beef will harm reputation more

FUKUSHIMA -- Officials here are disappointed that a new discovery of radioactive beef shipped from a Fukushima Prefecture farmer was discovered and caused the central government to delay lifting the ban on the prefecture's cattle shipments.

"Fukushima products have taken another blow to their reputation," said an official.

The central government had planned to lift bans on cattle shipments from Fukushima along with Miyagi Prefecture, but the ban lift for Fukushima was put off after levels of radioactive cesium exceeding safety standards were detected in beef shipped from an area near the Fukushima No. 1 Nuclear Power Plant.

The contaminated beef was from four cattle shipped from the Fukushima Prefecture town of Namie. The part of the town from where the cattle were shipped falls under a zone designated on April 22 to evacuate. All cattle shipped or evacuated from the zone since then have been screened for radioactive materials, but the cattle in question were shipped before the area was designated to evacuate.

The contaminated cattle were slaughtered on April 7 and 19, and their meat was being kept in refrigerated storage in Kawasaki by a Tokyo-based meat dealer.

According to the Kawasaki Municipal Government and the Ministry of Health, Labor and Welfare, the meat dealer did its own screening of the beef earlier this month and detected up to 1,000 becquerels of radioactive cesium per kilogram -- twice a provisional safety limit set by the central government. The Health Ministry also screened the beef on Aug. 19 and detected up to 997 becquerels.

The farmer who shipped the cattle had raised some 4,000 cattle in livestock barns in the Fukushima Prefecture village of Katsurao and city of Tamura, which both neighbor the town of Namie. The farmer evacuated outside Fukushima Prefecture after the accident at the power plant and since then is no longer farming.

The farmer reportedly explained that he or she did not give the cattle rice straw contaminated with radiation, which is thought to have caused other cases of irradiated cattle. To find the cause of the cattle's irradiation, the central and prefectural governments are investigating the conditions of the barns, water and feed given to the cattle.

Because refrigerated beef is sometimes stored for up to around two years, authorities intend to step up efforts to find any other contaminated beef that may be being held in storage.

In anticipation of the ban lifting, the Fukushima Prefectural Government has prepared a system to test all its cattle for radioactive material. "No more contaminated beef will hit the market," said a prefectural agricultural official.

"Even if shipments are resumed, farmers will not be able to make ends meet unless the price of beef returns to pre-nuclear disaster levels. We want the central government and Tokyo Electric Power Co. (which operates the stricken nuclear plant) to do all they can to dispel harmful rumors," said an official with JA Zen-noh Fukushima's stock breeding department.

(Mainichi Japan) August 20, 2011

Estimated yearly radiation dosage hits 508 mSv in town near nuke plant

High radiation levels of up to 508.1 millisieverts per year are estimated for areas within a 20-kilometer radius of the crisis-hit Fukushima No. 1 Nuclear Power plant in figures released by the government on Aug. 19.

The figures, released by the Ministry of Education, Culture, Sports, Science and Technology, are the first publicly released estimate of the yearly accumulated radiation dosage in 50 locations across eight municipalities in the 20-kilometer radius zone.

The highest figure was for the Koirino district of Okuma, Fukushima Prefecture, where the estimated yearly dosage was 508.1 millisieverts -- over 500 times the acceptable yearly level of 1 millisievert per year for artificial radiation dosage. The district is three kilometers west-southwest of the plant.

The figures are based on measurements taken at the 50 locations and a person being indoors for 16 hours and outdoors for eight hours every day. Estimations for March 12 through to Aug. 11 were based on those days' actual measurements. For Aug. 12 through to the end of the one year period, the average doses estimated from Aug. 9 and 11, the most recent data, were assumed to continue.

At 35 points, the level exceeded 20 millisieverts per year. The yearly radiation dosage at seven spots in the town of Okuma was estimated at over 100 millisieverts.

The Koirino district of Okuma was also highest for the most up-to-date estimate of hourly dosage, with 75 microsieverts per hour. That figure is below the 200 microsievert-per-hour figure used by the government as a basis for deciding whether residents can make short visits to their homes.

Other areas to receive high yearly estimates included the Kawabusa district of the town of Namie -- 20 kilometers northwest of the nuclear plant -- with 223.7 millisieverts per year, and the Nagatsuka district of Futaba -- five kilometers north-northwest of the plant -- with 172.4 millisieverts per year. However, in the Kitakiyohashi district of Namie, eight kilometers north of the plant, the level was 4.1 millisieverts per year, showing that radiation levels can vary greatly even within the same town.

Yoshihisa Matsumoto, an associate professor of radiobiology at the Tokyo Institute of Technology, said work to decontaminate the area will likely prove difficult.

"At the areas with high levels, the radiation exposure exceeds the amount that astronauts are exposed to during long stays on the International Space Station (about 1 millisievert per day), so decontamination is necessary for people to live there, but with radioactive materials spread all over in a wide area, the work will probably be very difficult. With regard to people making short visits to their homes, I don't think they will be adversely affected if they are only there for a few hours," he said.

(Mainichi Japan) August 20, 2011

Radiation fears hit Fukushima on multiple fronts

FUKUSHIMA -- This summer, some parks in this prefecture are devoid of children, parents having sent them on programs far away so they can play outside without worrying about radiation from the Fukushima No. 1 Nuclear Power Plant.

On Aug. 8, a group of 14 elementary and junior-high students were boarding a bus in the city of Date, one city where areas with high levels of radiation have been measured. The students had been invited by a prefectural support group to a two-week program in Aichi Prefecture in the southwest, where they would enjoy swimming and other sporting events. Many other support groups have organized similar programs.

Hiroaki Nagasho, 36, who sent his young daughter to participate in the Aichi trip, said, "I wanted to let her play outside as much as she wanted and release built-up stress."

A 41-year-old woman who had two daughters participating said, "I'm worried about what to do after they come back. It's not easy to move them to another school."

As of July 15, 7,672 elementary and junior high school students had been transferred to schools out of the prefecture. During the summer break, which is continuing now, an additional 1,081 were set for transfers. Furthermore, around 2,000 children at private kindergartens have been moved out of the prefecture.

As of July 28, the total number of people that had evacuated from the prefecture was at 48,903.

Tourism has also been hit hard. Normally, through educational field trips, Fukushima Prefecture is visited by about 8,000 groups a year for a total of around 700,000 visitors (counting repeat visitors as separate people.)

However, the Fukushima Prefecture Tourism & Local Products Association expects a 95 percent drop in those visitors this fiscal year. They say that even reservations for two to three years in the future are starting to be canceled.

Another area where the prefecture is hurting is in sales of its peach crop. Fukushima Prefecture is second only to Yamanashi Prefecture in its production of peaches, and now is peak harvesting season, but distrust of Fukushima products is dealing a heavy blow to sales. According to a Fukushima city tourism and agriculture organization, the peaches are being left off of department stores catalogs for the summer gift-giving period, and sales of peach gifts have fallen greatly.

Visitors are also sparse at shops and fruit orchards along "Fruit Line," a road in Fukushima city developed for tourism. Shinichi Katahira, chair of the tourism and agriculture organization, thinks the visitors during this year's Obon holiday were about one-tenth of what they were last year.

One orchard owner, Atsushi Konno, 59, said, "Peach trees don't wait. They just keep producing," as he continued picking fruits.

(Mainichi Japan) August 21, 2011

Radioactive decontamination unit to be set up in Fukushima

FUKUSHIMA (Kyodo) -- Nuclear disaster minister Goshi Hosono said Saturday that the government will **set up a task force to promote radioactive decontamination in areas surrounding the crippled Fukushima Daiichi nuclear power plant** probably next week.

The central government will also establish a decontamination promotion unit in Fukushima Prefecture to initially commence the process in the city of Date, Hosono said during a meeting with Fukushima Gov. Yuhei Sato at the prefectural government office.

In response, Sato told Hosono that the central government should take the initiative in the decontamination work.

After the meeting, Hosono visited areas in the towns of Futaba and Okuma located within 3 kilometers of the Fukushima plant and told reporters that the government will allow evacuees from the areas to visit their homes temporarily on Aug. 26 and Sept. 1 as scheduled.

The government has organized temporary home visits for many evacuees from the 20-km exclusion zone around the nuclear plant, which has been crippled since the March 11 earthquake and tsunami, to pick up personal belongings. But it has not yet permitted such visits for evacuees from areas located within a 3-km radius of the plant because of high radiation levels.

(Mainichi Japan) August 21, 2011

74 percent favor gradual reduction of nuclear power plants: Mainichi poll

Seventy-four percent of respondents to a poll by the Mainichi Shimbun expressed support for a gradual cutback on nuclear power plants in Japan, while only 11 percent demanded an immediate halt to nuclear energy.

The Mainichi poll also found that 56 percent are opposed to a proposed rise in the consumption tax and other taxes to help finance social security costs and reconstruction efforts in the aftermath of the March 11 Great East Japan Earthquake and tsunami while 41 percent were in favor.

The approval rating for Prime Minister Naoto Kan's Cabinet dropped 4 percentage points from the previous poll in July to 15 percent, the lowest since the launch of the government under the Democratic Party of Japan (DPJ) in September 2009. The Kan Cabinet's disapproval rating came to 63 percent, up from 56 percent in July.

Japan's energy policy and the pros and cons of a rise in the consumption tax from the current 5 percent are expected to be dominant topics in the upcoming DPJ presidential election to pick Kan's successor. The Mainichi poll's results are likely to have an impact on the election.

Kan has proposed an end to the nation's dependence on nuclear energy following the outbreak of the crisis at the Fukushima No. 1 Nuclear Power Plant, but it is not clear what direction his policy to promote renewable energy will take due to the prime minister's imminent departure.

Reflecting electricity shortages across Japan and anxiety about social and economic activities due to the ongoing Fukushima crisis, 74 percent were in favor of a gradual phase out of nuclear power plants while only 13 thought there was no such need.

When asked about food contamination by radioactive substances, 71 percent said they have harbored concerns, including 27 percent who are deeply worried, while 23 percent said they are not so anxious. Only 4 percent replied they have no apprehensions at all.

As for the DPJ's agreement with the largest opposition Liberal Democratic Party (LDP) and the New Komeito party on a review of its manifesto for the 2009 House of Representatives election, including child allowances, 69 percent supported the plan but 27 percent were against the move. The support rate for the review accord among DPJ supporters reached 68 percent.

One of two new solar arrays in the Ogishima district of Kawasaki is seen in this aerial photo on Aug. 5.
(Mainichi)

Under a divided Diet where the opposition camp controls the House of Councillors, 70 percent of respondents to the Mainichi poll expressed their support for "a partial coalition" by the ruling DPJ, the LDP and other parties depending on specific issues involved. Only 17 percent said they support "a grand coalition" by the nation's largest parties.

Public support for the ruling DPJ stood at 13 percent, unchanged from the previous poll while that for the LDP rose 6 points to 22 percent, a level seen at the end of the last LDP-led government in 2009. The poll found that 49 percent did not have any particular party to support, down 5 points from July.

(Mainichi Japan) August 22, 2011

Some areas near Fukushima plant to remain no-go zones: gov't sources

Workers spread lining sheets in a huge trench dug to bury radiation-contaminated topsoil collected from the ground of Yasawa Elementary School and Kindergarten in Minami-Soma, about 20 kilometers away from the

tsunami-crippled Fukushima Dai-ichi nuclear facility, in Fukushima Prefecture, northeastern Japan, Thursday, Aug. 18, 2011.(AP Photo/Hiro Komae)

TOKYO (Kyodo) -- The government has decided to keep certain areas showing high levels of radiation around the radiation-leaking Fukushima Daiichi nuclear power plant as no-go zones even after the damaged complex is brought to a cold shutdown, government sources said Sunday.

Areas within 20 kilometers of the plant that will not see the lifting of the no-go zone designation will be determined after results of radiation monitoring tests are examined in the future, the sources said, adding it is unavoidable some areas will remain no-go zones for a long time.

The government will consider purchasing those long-term restricted areas and owning them, the sources said.

Prime Minister Naoto Kan intends to visit areas affected by the nuclear crisis triggered by the massive March 11 earthquake and tsunami possibly next Saturday to explain how the government will support those still living as evacuees and unable to return to their homes, the sources said.

The government has set next January as a target deadline for completing the "step 2" phase of achieving a cold shutdown of the damaged reactors at the plant. The government also plans to start considering lifting the no-go zone on condition that the release of radioactive material will be strictly controlled.

According to the science ministry's estimation of annual accumulated radiation exposure, released Friday, over 100 millisieverts of radiation exposure were expected for 15 out of 50 surveyed points in the no-go zone, exceeding the International Commission on Radiological Protection's guideline of 20-100 millisieverts even at the time of an emergency.

Given the high levels of exposure, the government is now considering it will have to exclude some areas when lifting the no-go zone.

L'uranium enrichi au laser, nouvelle peur nucléaire

AFP | 21.08.11 | 19h28 • Mis à jour le 21.08.11 | 21h51

Le groupe industriel américain General Electric (GE) prévoit de relancer à grande échelle aux Etats-Unis un procédé d'enrichissement de l'uranium au laser, ce qui suscite des craintes relatives à la prolifération nucléaire, rapporte dimanche 21 août, le *New York Times*.

Le quotidien américain publie une longue enquête selon laquelle *"General Electric teste avec succès depuis deux ans un procédé d'enrichissement de l'uranium au laser"* dans une installation située près de Wilmington, en Caroline du Nord (Est des Etats-Unis). Cité par le quotidien, Christopher Monetta, le président de **Global Laser Enrichment, la filiale de GE et du groupe japonais Hitachi qui exploite cette**

installation, a indiqué: *"Nous sommes actuellement en train de parfaire les plans"* d'un projet d'extension.

Selon l'article, le groupe *"a demandé aux autorités fédérales l'autorisation de construire une usine d'un coût d'un milliard de dollars afin de produire du combustible nucléaire en grande quantité"* et s'est vu promettre une réponse *"d'ici à l'année prochaine"*. Le journal écrit que, selon M. Monetta, *"l'usine prévue enrichirait chaque année suffisamment d'uranium pour alimenter jusqu'à 60 grands réacteurs"*.

Selon le New York Times, le projet de GE et Hitachi suscite les craintes d'associations soucieuses de la non-prolifération. Elles redoutent que le procédé puisse tomber entre les mains d'Etats comme l'Iran ou de groupes terroristes et puisse être utilisé facilement à petite échelle pour fabriquer une bombe nucléaire, ou simplement *"la révélation au public qu'un demi-siècle d'échec de l'enrichissement au laser semble en train de s'achever"*.

L'enrichissement de l'uranium a pour but d'augmenter la teneur du minerai brut en isotope 235. Lorsqu'il est enrichi à environ 4 % en uranium 235, le matériau radioactif peut être utilisé comme combustible dans une centrale nucléaire. A 90 %, il peut servir à fabriquer une bombe atomique.

La technique de l'enrichissement de l'uranium au laser est connue depuis les années 1960 mais la recherche sur le sujet a été plus ou moins abandonnée, car la méthode apparaissait difficile à rentabiliser, jusqu'à ce que des chercheurs australiens mettent au point un procédé satisfaisant au milieu des années 1990, écrit le journal. Selon l'article, GE a racheté en 2006 leur brevet baptisé Silex, acronyme anglais pour *"séparation des isotopes par excitation au laser"*.

L'Iran, dont les activités d'enrichissement de l'uranium inquiètent les Occidentaux, utilise pour cela des centrifugeuses, ce qui demande de grosses installations industrielles, difficiles à camoufler.

En ordonnant en février 2010 la production d'uranium enrichi à 20%, le président iranien Mahmoud Ahmadinejad avait affirmé que son pays était désormais capable d'enrichir de l'uranium en utilisant le laser.

Fukushima gov't seeks lifting of ban on cattle shipments

FUKUSHIMA (Kyodo) -- The Fukushima prefectural government on Monday called on the central government to lift its ban on cattle shipments from the prefecture, saying the cause of newly discovered cattle's radioactive contamination has been determined.

The government of Fukushima Prefecture, where the crippled Fukushima Daiichi nuclear power plant is located, has reported that 12 cattle from the town of Namie, Fukushima Prefecture were found to be contaminated with radioactive cesium exceeding the government-set limit **because they were fed cesium-tainted hay**.

The central government decided Friday not to lift its ban on cattle shipments from Fukushima Prefecture at this time as contaminated beef from there has been newly detected. It did give the green

light to shipments from Miyagi Prefecture, after initially planning to lift the ban on Fukushima and Miyagi simultaneously.

The farm that shipped the cattle in question said contaminated rice straw had not been fed to those cows as they were fed imported hay. That prompted the central government to quickly adopt the position the cause of the contamination must be determined before the ban on cattle shipments from Fukushima can be lifted.

According to the Fukushima government's investigation, the 12 cattle in question from Namie **were raised in a cattle shed without side walls, thus allowing outdoor air to enter easily.**

The livestock farmer in Namie fed imported hay left in an aisle of the cattle house after the eruption of the nuclear crisis at the Fukushima power complex, triggered by the March earthquake and tsunami.

(Mainichi Japan) August 23, 2011

Gov't should take responsibility for decontaminating soil tainted with radiation

The Japanese government appears prepared to go ahead with the decontamination of soil tainted with radioactive substances leaking from the tsunami-hit Fukushima No. 1 Nuclear Power Plant after the ruling and opposition parties agreed to enact legislation to make up for a legal flaw.

The ruling Democratic Party of Japan (DPJ) and two key opposition parties -- the Liberal Democratic Party (LDP) and New Komeito -- have agreed on the details of a special measures bill on land decontamination and disposal of rubble contaminated with radioactive substances. The bill likely will be submitted to the Diet as a lawmaker-initiated bill and become law during the ongoing session.

The Waste Disposal and Public Cleaning Law does not cover the disposal of rubble contaminated with radioactive substances. If enacted, the new law would be the first to cover how to deal with radiation contamination outside the premises of nuclear power plants.

Under the bill, the environment minister would designate areas with high levels of radiation as "special areas." The national government would decontaminate the designated areas based on a plan it would work out after listening to the opinions of the local governments concerned. The minister would also designate areas where radioactive rubble must be disposed of, and the national government would collect such waste, and transport, store and dispose it at its own responsibility. The bill would require Tokyo Electric Power Co. (TEPCO), the operator of the crippled Fukushima power plant, to bear the costs of decontamination and disposal of rubble contaminated with radioactive substances as part of its compensation for the nuclear accident.

Even though the bill would clarify the central government's responsibility for radiation contamination countermeasures, many hurdles must be cleared before such measures are implemented. In particular, it is difficult to predict when the environment of the areas where residents have been evacuated can be improved to a level where they can come back and live safely **because such a large-scale decontamination operation is unprecedented anywhere in the world.**

Therefore, the national government is required to fully release information on how far it intends to reduce radiation levels in affected areas based on its monitoring and provide a thorough explanation.

The Education, Culture, Sports, Science and Technology Ministry has for the first time released its estimation of annual cumulative radiation levels at 50 locations in no-entry areas within 20 kilometers from the Fukushima No. 1 Nuclear Power Plant. **At 35 of the locations, the amount surpassed 20 millisieverts -- a level that requires residents to evacuate -- suggesting that extensive decontamination operations will be needed over a long period.**

The government should also fully release information suggesting that evacuated residents cannot easily return home.

Moreover, depending on radiation levels, it might not be realistic for residents to come home soon even if their neighborhoods were decontaminated in accordance with the bill.

Prime Minister Naoto Kan is expected to travel to Fukushima Prefecture later this week to explain to the local governments concerned as well as residents that even if decontaminated, some areas will likely remain unfit for living for many years.

If so, the prime minister must show concrete data and explain how long evacuated residents must wait until they are allowed to return home in order to win their understanding. Furthermore, Kan should also explain specific measures to extend assistance to residents of such areas, including where they will live for the time being.

Difficult challenges to removing rubble will likely emerge in the future, such as how to secure a site for the disposal of ash generated after rubble contaminated with radioactive substances is incinerated. Questions also remain as to whether the final disposal site should be created in Fukushima Prefecture or other areas. The national government must take all possible measures to ensure safety in disposing of contaminated rubble and **gain the understanding of local residents.**

(Mainichi Japan) August 23, 2011

Potent radiation leak halts water decontamination operations at Fukushima plant

Workers at the Fukushima No. 1 Nuclear Power Plant stand around the radioactive water decontamination system "Sally" in this photo provided by TEPCO.

Operations to decontaminate highly radioactive water at the crisis-stricken Fukushima No. 1 Nuclear Power Plant came to a 13-hour halt when **a section of pipe emitting 3 sieverts of radiation per hour in one decontamination system was discovered**, plant operator Tokyo Electric Power Co. (TEPCO) has announced.

According to TEPCO, the high radiation emissions from the pipe section were discovered at just after 7 a.m. on Aug. 22 while workers were doing the first ever change-out of a decontamination system part for absorbing radioactive cesium. Work on the part change was stopped immediately. After washing radioactive mud away from the area, radiation levels dropped, and decontamination operations resumed at about 8:15 p.m., though the delay pushed replacement of the cesium absorption component back to Aug. 23. TEPCO officials apparently still do not know what caused the radiation leak.

The water decontamination system, called "Sally," was built by electronics and heavy machinery giant Toshiba Corp. There are high expectations for Sally's performance after two other decontamination systems at the site -- one made in the United States and the other in France -- continued to have problems and delays.

This is the third time for high radiation emissions to be discovered at the plant in August. On Aug. 1, emissions of 10 sieverts per hour were detected coming from the substructure of exhaust pipes in the No. 1 and 2 reactor housings, while on Aug. 2 emissions of more than 5 sieverts per hour were found in the air conditioning room in the No. 1 reactor building.

(Mainichi Japan) August 23, 2011

Expert urges higher radiation exposure limit to be set for Fukushima

TOKYO (Kyodo) -- A Japanese nuclear expert called Tuesday for the planned annual radiation exposure limit for residents in areas close to the Fukushima Daiichi nuclear plant to be set at up to 5 millisieverts, instead of 1 millisievert as planned by the government.

The 5 millisievert limit would be more realistic for lifting evacuation advisories for residents as the government's planned annual limit of 1 millisievert or less may not be met in some areas, said Shunichi Tanaka, a former acting chairman of the Japan Atomic Energy Commission.

The government plans to include the annual limit of 1 millisievert when it drafts a basic radioactive decontamination policy on Friday.

"Past experience of decontamination has shown it would be very difficult to reduce annual radiation exposure to 1 millisievert," Tanaka told a regular meeting of the commission.

Tanaka has engaged in decontamination work in such areas as Iitate close to the nuclear plant, which released radioactive substances following explosions at reactor buildings after the March 11 earthquake and tsunami.

Last week, the government estimated annual radiation exposure of more than 100 millisieverts at 15 of 50 points located within a 20-kilometer radius of the plant. The highest estimate exceeded 500 millisieverts.

Tanaka also expressed doubt about the advisability of a Food Safety Commission recommendation that combined external and internal radiation exposure be limited to 100 millisieverts over a lifetime, saying it would be difficult for people to live in many areas of Fukushima Prefecture.

Tanaka noted that controlled storage sites may have to be designated in Fukushima Prefecture as **decontamination is expected to generate tens of millions of tons of radioactive waste including soil.**

Linda Gunter, Beyond Nuclear, 301.455.5655

Mother Nature sends warning as earthquake strikes where reactors sit

Takoma Park, August 23 – A 5.9 magnitude that was felt up and down the US east coast was centered in Mineral, Virginia, home to the two-reactor North Anna nuclear power plant operated by Dominion Energy. North Anna sits just 90 miles south of Washington, DC. The plant automatically shut down following a loss of offsite power, but electricity is still needed to cool the reactor core and fuel pools. "Once again, Mother Nature is warning us that nuclear power is the most brittle of electrical power systems," said Paul Gunter, director of Reactor Oversight for Beyond Nuclear. "In times of national crisis or natural disaster, nuclear power becomes more of a liability than an asset," he said. All but one of the four on-site emergency diesel generators at North Anna started up as needed for reactor cooling and safety systems. However, cooling systems for the two spent fuel pools loaded with nuclear waste do not automatically get switched over to emergency power systems. Several other reactor sites along the eastern seaboard reported "unusual events" to the U.S. Nuclear Regulatory Commission but no others were forced to shut down. "The Obama administration – which still presses for more nuclear plants – and the nuclear industry and its lapdog regulator refuse to learn the lessons of Fukushima even when they are brought right home by this powerful quake," said Linda Gunter, International Specialist at Beyond Nuclear. "Even the Japanese prime minister has acknowledged that Japan must move forward without using nuclear energy. Here at home it seems only public outrage can move our leaders. We got lucky again, this time, but at some point that luck will run out. We should not wait to pay that price but start a nuclear phase-out today."

The earthquake risks at North Anna were known as far back as 1970, a 1975 Washington Post article reveals. Then owner, Virginia Electric and Power Company, was fined an unprecedented \$60,000 for building the plant on a known fault line which consultants retained by Vepco claimed did not exist.

On-going updates about the post-quake status of US nuclear plants can be found on the Beyond Nuclear website, on Facebook and on Twitter.

Beyond Nuclear aims to educate and activate the public about the connections between nuclear power and nuclear weapons and the need to abandon both to safeguard our future. Beyond Nuclear advocates

Firms tied to mayor of Hokkaido town profited from local nuclear research center

Apartment blocks in Horonobe, Hokkaido, owned by a company connected to the town's mayor and rented to a JAEA nuclear research facility. (Mainichi)

HORONOBÉ, Hokkaido -- Two companies connected to the mayor here have been making some 40 million yen per year from a local nuclear research facility, it has been learned, sparking speculation that the facility holds undue influence over the leader of this northern town.

The Japan Atomic Energy Agency (JAEA)'s Horonobe Underground Research Center began renting two apartment complexes for its workers in fiscal 2001 from the firm Horonobe Shoji, where Mayor Akira Miyamoto's son serves as president and the mayor himself is a board member. The research center has furthermore contracted local security firm **Hokusei**, run by three of the mayor's family and where Miyamoto also served on the board of directors until just after he was elected mayor in 2002, to do security at the facility.

Miyamoto has stated that the contracts are not legally improper and that the business relationship with the research center is not a problem. According to the mayor and the nuclear facility, Horonobe Shoji has been paid about 9.6 million yen in rent for the two apartment blocks per year since the first contract in 2001, when the mayor was a town council member. Information obtained through public finance disclosure regulations reveals that Miyamoto continues to receive income from Horonobe Shoji, but exact amounts were not provided.

Meanwhile, the relationship between the research center and the second firm, Hokusei, began in 2003 with the rental of another apartment building for center staff at 4.8 million yen per year, as well as the first security contract. From fiscal 2003 to 2005 Hokusei was paid 5 million yen annually for security services at the nuclear facility. This has jumped to an annual income of 22 to 30 million yen after the introduction of competitive bidding in fiscal 2006, which Hokusei has won every year.

Regarding the apartments, Miyamoto has insisted there has been no wrongdoing, stating, "The local commerce and industry association received an inquiry from the underground research center saying it was short of housing for its workers. Several people and I worked together to take out loans and build housing. I have not been a part of the administration of either Horonobe Shoji or Hokusei since I became mayor."

The JAEA research center, meanwhile, insists that the limited tender contracts with the two firms were signed "because there was so little available to choose from," adding, "These contracts began before Mr. Miyamoto became mayor, so there is no problem."

Since construction of the research center began in 2003, Horonobe has received more than 100 million yen in subsidies for power-producing municipalities. According to town government calculations, the nuclear facility has poured some 500 million yen into the community in wages and work orders, of which the two firms connected to the mayor account for about 10 percent. In these years, Miyamoto conducted a public relations campaign to attract further research facilities to the town.

Hokkaido town agonizes over permanent radioactive waste disposal, 'nuclear money'

High-level radioactive waste is the "nuclear garbage" left over in the form of spent fuel. Japan has still not determined a permanent disposal site for this waste, but back in the 1980s, Horonobe, a small town in Hokkaido, became the only municipality in Japan to offer to host a research center for the storage of radioactive waste. This June, the town once again wrangled over the problem of "nuclear plant money."

Construction plans for a storage center in Horonobe were abandoned due to opposition from local residents and surrounding communities, and the town, the prefecture of Hokkaido and business operators eventually signed an accord that banned the introduction of radioactive materials. Today, Horonobe is the location of the "Horonobe Underground Research Center," where the Japan Atomic Energy Agency conducts research on disposal techniques.

At a municipal assembly session on June 16, Akira Miyamoto, mayor of Horonobe, unleashed controversy by saying that the matter of "documentary investigation" regarding the construction of a permanent disposal site that is being solicited by the Agency for Natural Resources and Energy of the Ministry of Economy, Trade and Industry is "an issue coming up for consideration."

In exchange for hosting the Underground Research Center, Horonobe receives more than 100 million yen annually, a subsidy stipulated by the so-called "Three Power Laws." Consenting to "documentary investigation" will entitle the town to an additional subsidy of 1 billion yen per annum, expandable to a maximum of 2 billion yen. This is a tempting offer for a town with a budget that barely exceeds 4 billion yen. The mayor retracted his statement after criticism from local residents, but said: "An associated facility that makes efficient use of the Underground Research Center might still be considered."

The above-mentioned accord forbids the selling or lend-leasing of the Underground Research Center to operators of permanent waste disposal businesses. Nevertheless, the Nuclear Waste Management Organization of Japan (NUMO), which conducts such operations, mentioned in a business report last year that "joint research at the Underground Research Center is being considered." (The remark was deleted after protests from civic groups.) The Agency for Natural Resources and Energy has also stated that the accord does not exempt Hokkaido from the possibility of documentary investigations.

The Underground Research Center held a meeting in July to explain the situation to local residents, who threw out questions like: "Can you assure us of the safety of a disposal site that has to last for 100,000 years, when they can't even contain the incident at Fukushima?" Yet both the national government and operators still show signs of wanting to proceed with permanent disposal operations.

Rokkasho, a village in Aomori Prefecture, is the location of a nuclear fuel reprocessing plant and also of a temporary storage facility for nuclear waste. Aomori Prefecture has exchanged a pledge with the government stipulating that "Aomori Prefecture will not be used as a permanent disposal site" and the village says it will insist that the promise be kept. However, with a large-scale nuclear facility already in place, feelings in Rokkasho are somewhat different from those in Horonobe.

One village assembly member said: "Lots of people are resigned to the idea, since they can't seem to find anywhere else to put it."

The temporary facility presently stores 1,457 vitrified rods of high-level nuclear waste. The storage building itself is of concrete, and a former high-ranking official of the municipal government comments: "If a disaster or a terrorist incident happens here, the damage will be incomparably worse than in Fukushima. Even for temporary storage, an underground facility is needed. If it's the best thing for our country, we're resigned to our village being the final disposal site."

Rokkasho went through a period of contention that split the village in two, but it decided to throw in its lot with national policy and accept the fuel reprocessing plant. Subsidies and property taxes have made

the municipality so rich that it could afford to spend 2.3 billion yen in providing each of its 4,500 households with videophones. An official of Rokkasho's Commerce and Industry Association is angry about Prime Minister Naoto Kan's call to "shift away from nuclear power."

"Petrochemical complexes and the nuclear-powered ship Mutsu -- the government keeps holding up these wonderful rose-colored projects, and then letting them come to nothing. We've been led around by the nose. Now they're saying: No more nuclear recycling. In that case, maybe we'll just have to insist that they remove all the waste they've left here."

Plant workers' radiation exposure from water-treatment piping within limit

Workers' exposure to radiation coming from piping in a water decontamination system at the Fukushima No. 1 Nuclear Power Plant was within the site's safety limits, the Tokyo Electric Power Co. (TEPCO) has announced.

According to TEPCO, the highest exposure a worker had was 3.47 millisieverts. The site's safety limit for workers' exposures is five millisieverts.

The radiation leak was found from piping in "Sally," a newly installed water decontamination system made by Toshiba. On the morning of Aug. 22, a high level of about three sieverts per hour was found while 23 workers were taking turns to replace a part of the system designed to absorb radioactive cesium.

"The clump (of cesium thought to have stuck to the piping where the high radiation levels were found) is thought to have been a few grams' worth, and we do not know why it stuck to the piping," said Junichi Matsumoto, deputy chief of TEPCO's nuclear power division.

TEPCO also revealed that a very small water leak had been found in equipment circulating and cooling the water for the No. 4 reactor unit's spent-fuel pool. The leak was discovered coming from a stainless steel pipe in the unit's waste-processing building, dripping about once every 30 seconds.

The concentration of radioactive material in the No. 4 reactor unit's spent-fuel pool is relatively low, at about 10 becquerels per liter. **A container was placed to catch the leak** and the circulation equipment is still running.

Virginia nuclear power plant on alert

Tuesday's magnitude-5.8 earthquake in the US state of Virginia has cut electricity to a nuclear power plant, prompting it to be placed on alert status.

The **two-reactor North Anna Power Station**, located about 24 kilometers from the quake's epicenter, shut down automatically after the power loss.

The alert status is the second-lowest of four emergency classifications set by the US Nuclear Regulatory Commission.

The watchdog said the shutdown is safe and poses no risk, as **power is being provided by three of four emergency diesel generators and the plant's cooling system is operating properly**.

The commission continues to monitor the situation as **one of the generators stopped working due to a coolant leak**.

The US East Coast rarely has earthquakes. Tuesday's quake was the first with a magnitude of more than 5.0 in Virginia since 1897.

Expert urges higher radiation exposure limit to be set for Fukushima

TOKYO (Kyodo) -- A Japanese nuclear expert called Tuesday for the planned annual radiation exposure limit for residents in areas close to the Fukushima Daiichi nuclear plant to be set at up to 5 millisieverts, instead of 1 millisievert as planned by the government.

The 5 millisievert limit would be more realistic for lifting evacuation advisories for residents as the government's planned annual limit of 1 millisievert or less may not be met in some areas, said Shunichi Tanaka, a former acting chairman of the Japan Atomic Energy Commission.

The government plans to include the annual limit of 1 millisievert when it drafts a basic radioactive decontamination policy on Friday.

"Past experience of decontamination has shown it would be very difficult to reduce annual radiation exposure to 1 millisievert," Tanaka told a regular meeting of the commission.

Tanaka has engaged in decontamination work in such areas as Iitate close to the nuclear plant, which released radioactive substances following explosions at reactor buildings after the March 11 earthquake and tsunami.

Last week, the government estimated annual radiation exposure of more than 100 millisieverts at 15 of 50 points located within a 20-kilometer radius of the plant. The highest estimate exceeded 500 millisieverts.

Tanaka also expressed doubt about the advisability of a Food Safety Commission recommendation that combined external and internal radiation exposure be limited to 100 millisieverts over a lifetime, saying it would be difficult for people to live in many areas of Fukushima Prefecture.

Tanaka noted that controlled storage sites may have to be designated in Fukushima Prefecture as **decontamination is expected to generate tens of millions of tons of radioactive waste including soil.**

Firms tied to mayor of Hokkaido town profited from local nuclear research center

Apartment blocks in Horonobe, Hokkaido, owned by a company connected to the town's mayor and rented to a JAEA nuclear research facility. (Mainichi)

HORONOBE, Hokkaido -- Two companies connected to the mayor here have been making some 40 million yen per year from a local nuclear research facility, it has been learned, sparking speculation that the facility holds undue influence over the leader of this northern town.

The Japan Atomic Energy Agency (JAEA)'s Horonobe Underground Research Center began renting two apartment complexes for its workers in fiscal 2001 from the firm Horonobe Shoji, where Mayor Akira Miyamoto's son serves as president and the mayor himself is a board member. The research center has furthermore contracted local security firm **Hokusei**, run by three of the mayor's family and where Miyamoto also served on the board of directors until just after he was elected mayor in 2002, to do security at the facility.

Miyamoto has stated that the contracts are not legally improper and that the business relationship with the research center is not a problem. According to the mayor and the nuclear facility, Horonobe Shoji has been paid about 9.6 million yen in rent for the two apartment blocks per year since the first contract in 2001, when the mayor was a town council member. Information obtained through public finance disclosure regulations reveals that Miyamoto continues to receive income from Horonobe Shoji, but exact amounts were not provided.

Meanwhile, the relationship between the research center and the second firm, Hokusei, began in 2003 with the rental of another apartment building for center staff at 4.8 million yen per year, as well as the first security contract. From fiscal 2003 to 2005 Hokusei was paid 5 million yen annually for security

services at the nuclear facility. This has jumped to an annual income of 22 to 30 million yen after the introduction of competitive bidding in fiscal 2006, which Hokusei has won every year.

Regarding the apartments, Miyamoto has insisted there has been no wrongdoing, stating, "The local commerce and industry association received an inquiry from the underground research center saying it was short of housing for its workers. Several people and I worked together to take out loans and build housing. I have not been a part of the administration of either Horonobe Shoji or Hokusei since I became mayor."

The JAEA research center, meanwhile, insists that the limited tender contracts with the two firms were signed "because there was so little available to choose from," adding, "These contracts began before Mr. Miyamoto became mayor, so there is no problem."

Since construction of the research center began in 2003, Horonobe has received more than 100 million yen in subsidies for power-producing municipalities. According to town government calculations, the nuclear facility has poured some 500 million yen into the community in wages and work orders, of which the two firms connected to the mayor account for about 10 percent. In these years, Miyamoto conducted a public relations campaign to attract further research facilities to the town.

Panel cuts estimated release of radiogens from Fukushima plant

In this Monday, Aug. 1, 2011 photo released by Tokyo Electric Power Co. on Tuesday, Aug. 2, a worker in protective gear measures radiation levels near a duct connected to a ventilation stack between the Unit 1 and Unit 2 reactors at the crippled Fukushima Dai-ichi nuclear power plant in Okuma, Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

TOKYO (Kyodo) -- The amount of radioactive substances emitted into the atmosphere from the crippled Fukushima Daiichi nuclear power plant is now estimated at 570,000 terabecquerels, down from an earlier estimate of 630,000 terabecquerels, the chairman of the Nuclear Safety Commission said Wednesday.

Given a large margin of error in an estimate of this kind, however, the figure "may change greatly" as more data on the nuclear accident become available, Haruki Madarame said.

The Nuclear Industrial and Safety Agency separately estimates the total amount of radioactive substances released into the air from the plant at 770,000 terabecquerels.

In the Chernobyl nuclear accident of 1986, an estimated 5.2 million terabecquerels of radioactive substances were discharged into the atmosphere.

The earlier estimate was revised based on new data on the release of radioactive substances in the four days from March 12, when the first of a series of explosions occurred following the earthquake and tsunami that hit the plant on March 11.

According to the recalculated estimate by the Japan Atomic Energy Agency, 130,000 terabecquerels of iodine 131 and 11,000 terabecquerels of cesium 137 were emitted into the air from the nuclear plant in Fukushima Prefecture from March 11 through April 5, Madarame said.

Gov't to lift cattle shipment ban for Fukushima, Iwate, Tochigi

TOKYO (Kyodo) -- The Japanese government will lift on Thursday its ban on cattle shipments from Fukushima, Iwate and Tochigi prefectures, a senior government official said.

The ban was imposed following the discovery of radioactive cesium-contaminated beef in the wake of the nuclear crisis at the Fukushima Daiichi plant triggered by the March earthquake and tsunami.

Nobutaka Tsutsui, senior farm vice minister, told reporters that Prime Minister Naoto Kan approved the lifting of the ban.

A similar ban in Miyagi Prefecture was lifted Friday.

Fukushima had been expected to see the ban lifted last Friday along with Miyagi, but the government decided against it as contaminated beef from there had been newly detected.

According to government sources, the ban is set to be lifted as measures to protect the livestock from radioactive contamination have been compiled.

(Mainichi Japan) August 25, 2011

Towns hosting Fukushima plant consider making nearby area a nuclear waste site

In this June 4 file photo, a Toyota Prius sits abandoned on an earthquake-damaged road in Okuma, Fukushima Prefecture. The government has estimated radiation in the town's Koirino district for a yearly period ending in March 2012 at 508.1 millisieverts, around 500 times the safety limit for regular citizens regarding non-naturally occurring radiation. (Mainichi)

A selfless idea has begun to surface on the lips of people who lived near the Fukushima No. 1 Nuclear Power Plant.

"After the reactors are decommissioned, the national government would buy up the surrounding few kilometers of land and uses it as a final storage spot for high-level radioactive waste. We're ready to consider such an option," says Ken Otsuka, 61. He is a former town council member of Futaba, the town that holds the Number 5 and 6 reactors of the Fukushima No.1 plant.

A person standing next to such high-level radioactive waste would take a lethal dose in less than 20 seconds. It is said that this kind of waste needs to be stored away from humans for over 100,000 years

before it becomes safe. However, no such storage spot exists in Japan yet, nor has a location for creating one been chosen.

Otsuka continues: "If we are going to move away from nuclear energy, then we have to deal with the problem of high-level nuclear waste. It's hard, but I feel that having received the benefits of nuclear energy, we hold certain responsibilities."

Part of the reason for Otsuka's thinking is a feeling that revival of the town is hopeless. In July, he made a temporary return to his home and went to some fruit orchards he managed around seven to eight kilometers from the plant. The branches were laden with peaches and blueberries, none of which could be harvested.

"I've lost the will to continue farming there...," he says.

The situation is similar for the town of Okuma, which holds the No. 1 through 4 reactors. Seventy-year-old farmer Eiichi Tsukamoto, who is from the town, revealed, "At a meeting of town area representatives, there was discussion on if we can't return to our homes, then the only option is to have the government buy up the land and use it for storing high-level nuclear waste."

Although Okuma Mayor Toshitsuna Watanabe, 64, says, "Residents will not accept the town being turned into a nuclear waste site. I want the national government to take responsibility and find another location," he struggles to envision what the town's future will be.

Senior officials of the town say, "We want to allow elderly residents (for whom long-term radiation effects are less of an issue) to return within two or three years. But young residents won't be able to return for around 10 years." Without the power of young people, though, the town's recovery will be shrouded in doubt.

Mayor Watanabe does have a vision for the town: becoming a base for national research on low-level radiation exposure and decontamination technology. "I want to turn this awful experience into something positive," he says.

Regardless, both towns now face a reality very different from the prosperity they hoped for when they invited the Fukushima plant.

Accident highlights close ties between local communities and nuke plants

The accidents at the Fukushima No. 1 and No. 2 nuclear power plants have underscored how deeply local communities are linked to the plants and their operator Tokyo Electric Power Co. (TEPCO).

Eiichi Tsukamoto, a 70-year-old man from the Fukushima Prefecture town of Okuma, had been a subcontract nuclear plant worker until five years ago.

"I was really happy that I didn't have to work away from home any longer," he said.

After graduating from high school in 1959, he worked away from home every winter. When he was a construction worker for the metropolitan expressways being built at a fast pace ahead of the Tokyo Olympics in 1964, he shared a room with 20 people and received 800 yen a day.

Five years later, he took part in the construction of the nuclear power plants, and his life completely changed. His daily wage surged to 1,000 yen to 1,500 yen, and he could even work on farms on weekends. At one point, his annual income reached 16 million yen, including agricultural income.

"I don't have any grudge against TEPCO. My whole family wants to be of help to TEPCO," he said.

His two sons are subcontract workers for a plant maker and are involved in work to bring the disaster-crippled Fukushima No. 1 Nuclear Power Plant under control.

In Okuma and the neighboring towns of Futaba and Tomioka -- which are hosts of the Fukushima No. 1 and No. 2 nuclear power plants -- TEPCO workers have also served as town assembly members while belonging to TEPCO's labor union.

One of them, Koji Igari, 59, a member of the Tomioka Town Assembly, works at the Fukushima No. 2 plant. His daily chores, however, are filled with work as a town assembly member.

"Because of the unique feature of nuclear power, I also work as a liaison between the administration (and TEPCO)," Igari said. He receives salaries both as an assembly member and as a TEPCO employee.

Following the revelation in 2002 that TEPCO had covered up trouble at its nuclear power plants, a liaison council was set up in 2003 involving TEPCO, the Economy, Trade and Industry Ministry's Nuclear and Industrial Safety Agency (NISA) and four municipalities hosting the Fukushima No. 1 and No. 2 nuclear power plants.

Each municipality selected five council members from its residents, and they held meetings regularly in an "attempt to ensure transparency," according to a TEPCO official. A newsletter was distributed to each household after every meeting.

Masazumi Ando, a 56-year-old council member from Tomioka, however, noticed that a tough question he had posed during a meeting was not carried in the newsletter several years ago. When he asked TEPCO about the matter, the utility admitted that the newsletter was edited by the firm.

"I got upset and told them, 'Isn't it a setup?' Since then, the town office has edited the newsletter," he said.

He says he felt there were too many council members with ties to TEPCO and authorities.

"Every time before a meeting started, members would have friendly chats, with one saying to the head of a nuclear plant, 'Thank you for treating me the other day,'" he said.

The council has not held a meeting since the nuclear accident in March.

'Hot spot' areas found in Fukushima city worry 'goya' growers

FUKUSHIMA -- A number of areas with comparatively high radiation levels, called "hot spots," have been found in the city of Fukushima in the wake of the accident at the Fukushima No. 1 Nuclear Power Plant, even though the prefectural capital is some 60 kilometers away from the plant.

One such area, the Onami district in the eastern part of the city of Fukushima, produces bitter gourds (goya) as a local specialty. Producers, however, are concerned about this year's shipment of goya.

The Onami district is next to Ryozenmachi in the Fukushima Prefectural city of Date, which was partially designated as a specially recommended evacuation location. In a prefectural survey in late July, high levels of radiation at 2.5 microsieverts or more per hour were detected at 37 out of 370 houses in Onami. At one of them, the radiation levels even measured 3 microsieverts per hour -- close to the 3.2 microsievert level set as a standard for special evacuation recommendations.

A local woman initiated goya growing in Onami in 1999. After her retirement from an insurance company, Hisako Kurihara, 76, was looking for some activities to attract women belonging to the local agricultural cooperative apart from Hula dance and other recreational activities.

One day, she saw goya at the agricultural cooperative and learned that growing goya does not require pesticide spraying because the plant is resistant to disease and pests. Kurihara proposed that members of the female department of the agricultural cooperative grow goya. They eventually started growing goya in their respective fields.

Since a distributor they buy goya seedlings from was affected by the nuclear accident, goya planting was delayed by two months this year. Furthermore, since some women gave up on growing goya out of concerns for harmful rumors, this year's shipment volume has plunged to a half that of a year earlier. Even though the amount of radioactive materials detected in their goya was less than about 1/30 of the government-set provisional safety limit, no supermarkets have accepted their products.

After her husband died in January this year, goya has been a source of emotional support for Kurihara whenever she distributed her products to her acquaintances.

"Goya is one of the only few vegetables that women at our age can grow without hard physical labor. If we evacuate here and leave our fields unattended, we would no longer be able to grow goya," another female grower said.

After the "hot spots" issue surfaced in May, the central government designated some households in Date as specially recommended evacuation spots on June 30. Since then, the number of such locations has been on the increase, with a number of areas in the cities of Soma and Fukushima now under consideration for designation.

"While the designation for emergency evacuation preparation zones is to be lifted, the number of special recommendation evacuation spots has been on the rise. We can't draw a road map for recovery," lamented a senior Fukushima Prefectural Government official.

So far, households where accumulated radiation exposure doses were estimated to reach 20 millisieverts a year and those with babies, infants and pregnant women near such households have been designated as specially recommended evacuation spots. Since designated households will be compensated by Tokyo Electric Power Co. (TEPCO), the operator of the crippled Fukushima No. 1 Nuclear Power Plant, many households -- mainly those with children -- call for their homes to be designated. There are, meanwhile, residents who don't welcome such a move, saying the designation would adversely affect the image or the liveliness of their towns.

The fact that local municipalities and private organizations have been conducting more meticulous radiation surveys have also contributed to the rise in the number of hot spots. Highly radioactive spots were newly found in the Fukushima Prefecture city of Nihonmatsu and other areas in August. More than 5 1/2 months after the nuclear accident, fear of radiation has been steadily growing among Fukushima Prefecture residents.

(Mainichi Japan) August 25, 2011

Japan to seek to reduce children's radiation dose by 60% in 2 yrs

TOKYO (Kyodo) -- Japan will seek to halve the amount of radiation in residential areas around the crisis-hit Fukushima Daiichi nuclear power plant and cut children's daily radiation dose by 60 percent over the next two years, a document on radiation decontamination policy showed Wednesday.

The policy is to be endorsed Friday by a government task force dealing with the nuclear crisis triggered by the devastating March 11 earthquake and ensuing tsunami.

The document also showed that the state will take responsibility for securing places to dispose of contaminated soil, while acknowledging the need to temporarily keep it in local areas for some time.

To realize the goals set in the emergency policy, the government will lead decontamination activities to scale down areas where radiation exposure is expected to top 20 millisieverts a year, such as the 20-kilometer radius of the plant designated as a no-entry zone, it said.

If there is a request, local governments can clean up the contamination based on the premise that safety is assured, receiving support from the state, according to the text.

Efforts to contain the nuclear crisis are showing some progress, with a new system to cool the crippled nuclear reactors activated at the Fukushima plant in northeastern Japan.

The government and plant operator Tokyo Electric Power Co. have set next January as a target deadline for completing what it calls the "step 2" phase of achieving a cold shutdown of the plant.

Gov't radiation decontamination team begins operations at Fukushima hotspots

A member of a government decontamination team checks radiation levels at a playground in Date, Fukushima Prefecture, on Aug. 24. (Mainichi)

A team formed by the government to start decontaminating areas of Fukushima Prefecture where radioactive materials have been scattered by the disaster at the Fukushima No. 1 Nuclear Power Plant began operations on Aug. 24.

The team is comprised of officials of the Environment Ministry, the Cabinet Office and the Japan Atomic Energy Agency (JAEA). It will conduct on-site tests in places with comparatively high radiation emissions, devise efficient methods for bringing the emissions down, and provide local governments with technical advice.

"The nuclear crisis has calmed down somewhat," state minister for the nuclear disaster Goshi Hosono said at the team's opening ceremony in the city of Fukushima. "But we haven't yet moved to deal with

the radioactive contamination problem. The future of Fukushima Prefecture hangs on decontamination efforts."

After the ceremony, Hosono headed to a radiation hotspot recommended for evacuation in the city of Date to inspect radiation testing that had begun the previous day.

"It won't likely take a long time before the government begins full-scale decontamination operations," Hosono told reporters. "I'd like to expand the operations at once after establishing effective methods."

A 61-year-old resident of the hotspot, meanwhile, said, "I'd really like to keep living in my house, so I hope they make quick progress with the decontamination."

Gov't to lift cattle shipment ban for Fukushima, Iwate, Tochigi

TOKYO (Kyodo) -- The Japanese government will lift on Thursday its ban on cattle shipments from Fukushima, Iwate and Tochigi prefectures, a senior government official said.

The ban was imposed following the discovery of radioactive cesium-contaminated beef in the wake of the nuclear crisis at the Fukushima Daiichi plant triggered by the March earthquake and tsunami.

Nobutaka Tsutsui, senior farm vice minister, told reporters that Prime Minister Naoto Kan approved the lifting of the ban.

A similar ban in Miyagi Prefecture was lifted Friday.

Fukushima had been expected to see the ban lifted last Friday along with Miyagi, but the government decided against it as contaminated beef from there had been newly detected.

According to government sources, the ban is set to be lifted as measures to protect the livestock from radioactive contamination have been compiled.

Virginia nuclear power plant on alert

Tuesday's magnitude-5.8 earthquake in the US state of Virginia has cut electricity to a nuclear power plant, prompting it to be placed on alert status.

The **two-reactor North Anna Power Station**, located about 24 kilometers from the quake's epicenter, shut down automatically after the power loss.

The alert status is the second-lowest of four emergency classifications set by the US Nuclear Regulatory Commission.

The watchdog said the shutdown is safe and poses no risk, as **power is being provided by three of four emergency diesel generators and the plant's cooling system is operating properly.**

The commission continues to monitor the situation as **one of the generators stopped working due to a coolant leak.**

The US East Coast rarely has earthquakes. Tuesday's quake was the first with a magnitude of more than 5.0 in Virginia since 1897.

Towns hosting Fukushima plant consider making nearby area a nuclear waste site

In this June 4 file photo, a Toyota Prius sits abandoned on an earthquake-damaged road in Okuma, Fukushima Prefecture. The government has estimated radiation in the town's Koirino district for a yearly period ending in March 2012 at 508.1 millisieverts, around 500 times the safety limit for regular citizens regarding non-naturally occurring radiation. (Mainichi)

A selfless idea has begun to surface on the lips of people who lived near the Fukushima No. 1 Nuclear Power Plant.

"After the reactors are decommissioned, the national government would buy up the surrounding few kilometers of land and uses it as a final storage spot for high-level radioactive waste. We're ready to consider such an option," says Ken Otsuka, 61. He is a former town council member of Futaba, the town that holds the Number 5 and 6 reactors of the Fukushima No.1 plant.

A person standing next to such high-level radioactive waste would take a lethal dose in less than 20 seconds. It is said that this kind of waste needs to be stored away from humans for over 100,000 years

before it becomes safe. However, no such storage spot exists in Japan yet, nor has a location for creating one been chosen.

Otsuka continues: "If we are going to move away from nuclear energy, then we have to deal with the problem of high-level nuclear waste. It's hard, but I feel that having received the benefits of nuclear energy, we hold certain responsibilities."

Part of the reason for Otsuka's thinking is a feeling that revival of the town is hopeless. In July, he made a temporary return to his home and went to some fruit orchards he managed around seven to eight kilometers from the plant. The branches were laden with peaches and blueberries, none of which could be harvested.

"I've lost the will to continue farming there...," he says.

The situation is similar for the town of Okuma, which holds the No. 1 through 4 reactors. Seventy-year-old farmer Eiichi Tsukamoto, who is from the town, revealed, "At a meeting of town area representatives, there was discussion on if we can't return to our homes, then the only option is to have the government buy up the land and use it for storing high-level nuclear waste."

Although Okuma Mayor Toshitsuna Watanabe, 64, says, "Residents will not accept the town being turned into a nuclear waste site. I want the national government to take responsibility and find another location," he struggles to envision what the town's future will be.

Senior officials of the town say, "We want to allow elderly residents (for whom long-term radiation effects are less of an issue) to return within two or three years. But young residents won't be able to return for around 10 years." Without the power of young people, though, the town's recovery will be shrouded in doubt.

Mayor Watanabe does have a vision for the town: becoming a base for national research on low-level radiation exposure and decontamination technology. "I want to turn this awful experience into something positive," he says.

Regardless, both towns now face a reality very different from the prosperity they hoped for when they invited the Fukushima plant.

Accident highlights close ties between local communities and nuke plants

The accidents at the Fukushima No. 1 and No. 2 nuclear power plants have underscored how deeply local communities are linked to the plants and their operator Tokyo Electric Power Co. (TEPCO).

Eiichi Tsukamoto, a 70-year-old man from the Fukushima Prefecture town of Okuma, had been a subcontract nuclear plant worker until five years ago.

"I was really happy that I didn't have to work away from home any longer," he said.

After graduating from high school in 1959, he worked away from home every winter. When he was a construction worker for the metropolitan expressways being built at a fast pace ahead of the Tokyo Olympics in 1964, he shared a room with 20 people and received 800 yen a day.

Five years later, he took part in the construction of the nuclear power plants, and his life completely changed. His daily wage surged to 1,000 yen to 1,500 yen, and he could even work on farms on weekends. At one point, his annual income reached 16 million yen, including agricultural income.

"I don't have any grudge against TEPCO. My whole family wants to be of help to TEPCO," he said.

His two sons are subcontract workers for a plant maker and are involved in work to bring the disaster-crippled Fukushima No. 1 Nuclear Power Plant under control.

In Okuma and the neighboring towns of Futaba and Tomioka -- which are hosts of the Fukushima No. 1 and No. 2 nuclear power plants -- TEPCO workers have also served as town assembly members while belonging to TEPCO's labor union.

One of them, Koji Igari, 59, a member of the Tomioka Town Assembly, works at the Fukushima No. 2 plant. His daily chores, however, are filled with work as a town assembly member.

"Because of the unique feature of nuclear power, I also work as a liaison between the administration (and TEPCO)," Igari said. He receives salaries both as an assembly member and as a TEPCO employee.

Following the revelation in 2002 that TEPCO had covered up trouble at its nuclear power plants, a liaison council was set up in 2003 involving TEPCO, the Economy, Trade and Industry Ministry's Nuclear and Industrial Safety Agency (NISA) and four municipalities hosting the Fukushima No. 1 and No. 2 nuclear power plants.

Each municipality selected five council members from its residents, and they held meetings regularly in an "attempt to ensure transparency," according to a TEPCO official. A newsletter was distributed to each household after every meeting.

Masazumi Ando, a 56-year-old council member from Tomioka, however, noticed that a tough question he had posed during a meeting was not carried in the newsletter several years ago. When he asked TEPCO about the matter, the utility admitted that the newsletter was edited by the firm.

"I got upset and told them, 'Isn't it a setup?' Since then, the town office has edited the newsletter," he said.

He says he felt there were too many council members with ties to TEPCO and authorities.

"Every time before a meeting started, members would have friendly chats, with one saying to the head of a nuclear plant, 'Thank you for treating me the other day,'" he said.

The council has not held a meeting since the nuclear accident in March.

'Hot spot' areas found in Fukushima city worry 'goya' growers

FUKUSHIMA -- A number of areas with comparatively high radiation levels, called "hot spots," have been found in the city of Fukushima in the wake of the accident at the Fukushima No. 1 Nuclear Power Plant, even though the prefectural capital is some 60 kilometers away from the plant.

One such area, the Onami district in the eastern part of the city of Fukushima, produces bitter gourds (goya) as a local specialty. Producers, however, are concerned about this year's shipment of goya.

The Onami district is next to Ryozenmachi in the Fukushima Prefectural city of Date, which was partially designated as a specially recommended evacuation location. In a prefectural survey in late July, high levels of radiation at 2.5 microsieverts or more per hour were detected at 37 out of 370 houses in Onami. At one of them, the radiation levels even measured 3 microsieverts per hour -- close to the 3.2 micorsievert level set as a standard for special evacuation recommendations.

A local woman initiated goya growing in Onami in 1999. After her retirement from an insurance company, Hisako Kurihara, 76, was looking for some activities to attract women belonging to the local agricultural cooperative apart from Hula dance and other recreational activities.

One day, she saw goya at the agricultural cooperative and learned that growing goya does not require pesticide spraying because the plant is resistant to disease and pests. Kurihara proposed that members of the female department of the agricultural cooperative grow goya. They eventually started growing goya in their respective fields.

Since a distributor they buy goya seedlings from was affected by the nuclear accident, goya planting was delayed by two months this year. Furthermore, since some women gave up on growing goya out of concerns for harmful rumors, this year's shipment volume has plunged to a half that of a year earlier. Even though the amount of radioactive materials detected in their goya was less than about 1/30 of the government-set provisional safety limit, no supermarkets have accepted their products.

After her husband died in January this year, goya has been a source of emotional support for Kurihara whenever she distributed her products to her acquaintances.

"Goya is one of the only few vegetables that women at our age can grow without hard physical labor. If we evacuate here and leave our fields unattended, we would no longer be able to grow goya," another female grower said.

After the "hot spots" issue surfaced in May, the central government designated some households in Date as specially recommended evacuation spots on June 30. Since then, the number of such locations has been on the increase, with a number of areas in the cities of Soma and Fukushima now under consideration for designation.

"While the designation for emergency evacuation preparation zones is to be lifted, the number of special recommendation evacuation spots has been on the rise. We can't draw a road map for recovery," lamented a senior Fukushima Prefectural Government official.

So far, households where accumulated radiation exposure doses were estimated to reach 20 millisieverts a year and those with babies, infants and pregnant women near such households have been designated as specially recommended evacuation spots. Since designated households will be compensated by Tokyo Electric Power Co. (TEPCO), the operator of the crippled Fukushima No. 1 Nuclear Power Plant, many households -- mainly those with children -- call for their homes to be designated. There are, meanwhile, residents who don't welcome such a move, saying the designation would adversely affect the image or the liveliness of their towns.

The fact that local municipalities and private organizations have been conducting more meticulous radiation surveys have also contributed to the rise in the number of hot spots. Highly radioactive spots were newly found in the Fukushima Prefecture city of Nihonmatsu and other areas in August. More than 5 1/2 months after the nuclear accident, fear of radiation has been steadily growing among Fukushima Prefecture residents.

Japan to seek to reduce children's radiation dose by 60% in 2 yrs

TOKYO (Kyodo) -- Japan will seek to halve the amount of radiation in residential areas around the crisis-hit Fukushima Daiichi nuclear power plant and cut children's daily radiation dose by 60 percent over the next two years, a document on radiation decontamination policy showed Wednesday.

The policy is to be endorsed Friday by a government task force dealing with the nuclear crisis triggered by the devastating March 11 earthquake and ensuing tsunami.

The document also showed that the state will take responsibility for securing places to dispose of contaminated soil, while acknowledging the need to temporarily keep it in local areas for some time.

To realize the goals set in the emergency policy, the government will lead decontamination activities to scale down areas where radiation exposure is expected to top 20 millisieverts a year, such as the 20-kilometer radius of the plant designated as a no-entry zone, it said.

If there is a request, local governments can clean up the contamination based on the premise that safety is assured, receiving support from the state, according to the text.

Efforts to contain the nuclear crisis are showing some progress, with a new system to cool the crippled nuclear reactors activated at the Fukushima plant in northeastern Japan.

The government and plant operator Tokyo Electric Power Co. have set next January as a target deadline for completing what it calls the "step 2" phase of achieving a cold shutdown of the plant.

Residents make first temporary visits to homes within 3 km of Fukushima plant

Residents dressed in clothing to protect them from radiation prepare to board a bus on Aug. 26 ahead of temporary visits to their homes within three kilometers of the crisis-hit Fukushima No. 1 Nuclear Power Plant. (Mainichi)

Residents from areas within a three-kilometer radius of the crisis-hit Fukushima No. 1 Nuclear Power Plant began returning to their homes for brief visits on Aug. 26, for the first time since the onset of the nuclear disaster.

A total of 117 people from 64 households in the Fukushima Prefecture town of Futaba made visits to their homes on Aug 26. In the town of Okuma, only residents of the rest home Sunlight Okuma, their families and home staff were eligible to return, and 35 people applied to do so.

Participants gathered at a gymnasium in Hirono, Fukushima Prefecture, on Aug. 26, and traveled to the restricted area by bus.

"I'm happy that we can temporarily return to our homes, but if this is going to be a place we can never come back to, I want the government to clearly tell us that," said 38-year-old Michiyo Suzuki, whose home is in Futaba.

Government officials say there are about 1,300 people from 400 households whose homes are located within three kilometers of the plant. A government survey on Aug. 24 found that the highest level of radiation was in Okuma, measuring 84.7 microsieverts per hour.

In the Hosoya district of Futaba, to which some residents temporarily returned, the radiation level measured 5 to 6 microsieverts per hour, while at the rest home in Okuma the level was 25 microsieverts per hour. Some residents of Okuma whose homes are within three kilometers of the plant will be allowed to make temporarily visits on Sept. 1.

(Mainichi Japan) August 26, 2011

Hokkaido Electric pressed staff to support 'pluthermal' nuke plan at symposium: JCP

SAPPORO -- The local branch of the Japanese Communist Party (JCP) is accusing Hokkaido Electric Power Co. of pressing employees to stage remarks during a 2008 symposium expressing support for a so-called "pluthermal" program at its nuclear power plant.

The revelations come as Kyushu Electric Power Co. has come under fire for asking workers and subsidiaries to make comments during a TV program expressing support for the planned resumption of operations at two reactors at its Genkai Nuclear Power Plant.

"The move was vicious and despicable, and betrayed the trust of Hokkaido residents," the JCP Hokkaido chapter said.

Hokkaido Electric's public relations division said it will conduct an in-house probe into the allegations.

Akira Terayama, director for crisis management at the Hokkaido Prefectural Government, also said the prefectural government is investigating the accusation.

The liaison division of Hokkaido Electric's Tomari Nuclear Power Plant sent an e-mail to 21 of the firm's divisions, urging employees to express support for the program at the plant's No. 3 reactor in the village of Tomari during a symposium that the prefectural government held in October 2008, the chapter said.

"In order to ensure that the program progresses smoothly, we hope that as many of you as possible will attend the symposium and express opinions in favor of the pluthermal program," the e-mail partly reads.

A total of 469 people attended the symposium, held in the neighboring town of Iwanai. An expert delivered a keynote speech on the program and a panel discussion was held during the event.

During a following question-and-answer session, nine of the participants asked questions, but most of them voiced opposition to or raised concerns about the program, while only a few expressed support, according to Tsutomu Ota, a JCP member of the Iwanai Municipal Assembly.

However, over half of the 237 people who responded to the organizer's survey following the symposium said the event largely cleared up their doubts about the program.

In the poll, 51 percent responded they felt that questions about the program were sufficiently discussed during the symposium, and 55 percent replied it helped deepen their understanding of the pluthermal program.

"The survey results were quite different from the atmosphere at the symposium, so I felt it was strange," assemblyman Ota said.

In March 2009, Gov. Harumi Takahashi announced that she had approved the program.

In response to an Economy, Trade and Industry Ministry probe conducted following the Kyushu Electric scandal, Hokkaido Electric claimed that there had been no problems involving another symposium that the national government held two months before the prefectural government's symposium.

Pluthermal refers to the use of plutonium-uranium mixed oxide fuel in light water nuclear reactors.

(Mainichi Japan) August 26, 2011

Gov't nuclear watchdog criticizes TEPCO for delayed release of tsunami estimate

A government nuclear watchdog has criticized the Tokyo Electric Power Co. (TEPCO) for not releasing an estimate it put together years ago that a tsunami over 10 meters high could hit the Fukushima No. 1 Nuclear Power Plant.

The estimate was put together in 2008 but not reported until March 7 this year -- only four days before the Great East Japan Earthquake.

"Even if it was only an estimate, TEPCO should have released the data earlier and explained it before experts because it far exceeded the previous estimate (that a tsunami of up to 5.7 meters could hit the No. 1 through No. 4 reactors)," said Yoshinori Moriyama, an official of the watchdog, the Nuclear and Industrial Safety Agency (NISA), during a press conference on Aug. 25.

TEPCO, however, refuted the criticism.

"We think that rather than relying on TEPCO to make its own estimations and evaluate the safety of the nuclear power plant, it was more rational to have the Japan Society of Civil Engineers (JSCE, which

decides tsunami-prevention measures for nuclear plants) make an evaluation, and TEPCO's report (to NISA) should come after that," said Junichi Matsumoto, deputy chief of TEPCO's nuclear power division.

Furthermore, while NISA maintains that its official in charge of earthquake-proof safety screening told TEPCO on March 7 after receiving the report that it needed to "take measures to safeguard the plant's equipment," TEPCO's Matsumoto denied this, saying, "That is not true."

TEPCO also revealed on Aug. 25 that the 2008 tsunami estimate was known about by its management. It says that in October 2008 it requested to the JSCE that it revise its guidelines for evaluating nuclear plants' tsunami-readiness, and that request was reported to Sakae Muto, then vice chief of TEPCO's nuclear power division. Muto later became TEPCO vice president and currently serves as an advisor to the utility.

(Mainichi Japan) August 26, 2011

NSC planning to set evacuation zones around nuclear power plants in advance

A working group in the Nuclear Safety Commission of Japan (NSC) is planning to set evacuation zones around nuclear power plants in case of a serious accident, NSC sources said.

Residents will be asked to evacuate from areas near nuclear power stations designated as preparatory action zones (PAZs) immediately if a serious accident occurs at a plant.

The panel is expected to set the specific areas of such zones by October, but it will basically follow **International Atomic Energy Agency guidelines, which stipulate that areas from three to five kilometers from nuclear plants should be designated as PAZs.**

PAZs will likely be incorporated in regional disaster prevention plans that local governments that host nuclear power stations will work out.

Currently, local governments designate areas within a radius of eight to 10 kilometers from atomic power stations as emergency planning zones -- where they will require residents to stay indoors and take other safety measures if a serious nuclear accident occurs. If a serious accident actually takes place, the local government concerned will be required to set evacuation zones while taking into account the anticipated spread of radioactive substances, such as those by the System for Prediction of Environmental Emergency Dose Information (SPEEDI).

However, local governments will require residents in PAZ areas to promptly evacuate from their neighborhoods if a serious nuclear accident occurs.

(Mainichi Japan) August 27, 2011

Local leaders steamed at government's 'buck-passing' radiation decontamination plan

Local leaders in areas contaminated by the disaster at the Fukushima No. 1 Nuclear Power Plant are **angry and disappointed at the central government's decontamination plan, which dumps much of the responsibility for the clean-up on municipalities.**

The central government's decontamination plan, finalized on Aug. 26, leaves clean-up of any sites emitting 20 millisieverts of radiation annually or less to municipal governments, while also calling on those same governments to create temporary storage areas for contaminated materials. Most of the sites with that level of radiation are in the emergency evacuation standby zone 20-30 kilometers from the stricken nuclear plant.

"It's very strange that the government would leave decontamination up to municipalities while at the same time seeking to bring down radiation emissions to 1 millisievert annually or less," said Motohoshi Yamada, mayor of Hirono, Fukushima Prefecture. Yamada apparently lambasted a visiting central government official on Aug. 25 over the plan. Hirono lies within the evacuation standby zone, though some 90 percent of the town's population has already fled.

"Our town's recovery will be delayed if we wait for the government's plan," Yamada continued, referring to the long list of tasks the municipality must undertake if it must tackle decontamination on its own, including finding a tainted material storage site and gaining support for it from local residents.

"There is just a mountain of issues to get through," the Hirono Municipal Government's disaster response headquarters commented.

Meanwhile, Mayor Katsunobu Sakurai of the city of Minamisoma -- a large part of which lies in the evacuation standby zone -- told the Mainichi, "I'd like to call on the government repeatedly to take its share of the responsibility for decontamination, including funding."

Minamisoma in fact already has an independent decontamination plan, which one senior city official said was put in place because "the central government and (plant operator) Tokyo Electric Power Co., which are supposed to take such action, aren't moving at all. I have no idea what they're thinking."

Hot-spot cleanups hampered by public resistance to local disposal sites

FUKUSHIMA -- Municipalities looking to clean up radiation "hot spots" caused by the disaster at the Fukushima No. 1 Nuclear Power plant are facing stiff local resident opposition as they search for temporary disposal sites for tainted materials.

Some 3,800 residents of Fukushima city's Watari district, site of a radioactive hot spot, carried out a major decontamination operation in late July, scraping out ditches and removing tainted topsoil. The city designated a site in the mountains as a temporary disposal area and trucked in the some 6,000 bags of contaminated material produced in the Watari operation. The disposal, however, was met with fierce opposition from locals around the mountain site.

"If the stuff had come from a local decontamination operation, then I'd just have to live with it. But I just can't agree with bringing it in from someplace else," said one 50-year-old housewife who lives only a few hundred meters from the disposal area. Aware of the local opposition, the city government has now begun looking for an alternate site.

Meanwhile, a Fukushima section of the Ministry of Land, Infrastructure, Transport and Tourism also hit a wall of public resistance when it tried to lay grass cut from the banks of a river in the city of Nihonmatsu on the river's bed. Previously, the grass had been used as animal fodder and compost. Since the grass has been contaminated by the nuclear disaster, however, the land ministry's Fukushima Office of Rivers and National Highways decided to lay the cuttings along the riverbed, at least temporarily. The public backlash against the plan began after a local resident saw the operation in progress.

"I've become very sensitive to the radiation issue so this is giving me a lot of stress," said one 44-year-old local resident. "Of course I don't want those cuttings to be left near my family."

(Mainichi Japan) August 27, 2011

No quick way to remove radioactive substances from soil: experts

Experts say there is no technology or machinery available that can quickly remove radioactive substances from soil. Steady and repeated efforts are required to gradually reduce radioactive substances by removing the surface from soil, mowing down grass, or scraping the matter off with water.

Under the government's basic scheme, radioactive substances can be removed from roads, roofs and playground equipment by rinsing with water in areas with radiation measuring less than 20 millisieverts per year.

But radioactive substances would spread if they seeped into soil or rivers. In the case of the Chernobyl nuclear accident in 1986, when radioactive substances on buildings were washed away, the levels of radiation where water reached rose several fold.

It is also difficult to secure places for radioactive waste disposal. According to an experiment conducted by the Date Municipal Government in Fukushima Prefecture, 35 metric tons of contaminated soil was produced when only soil around three houses was removed. The half-life of cesium-137 is 30 years, and therefore it needs to be stored and maintained for a long time.

Meanwhile, the government is responsible for removing radioactive substances in areas with radiation measuring 20 millisieverts or more. The cumulative level of radiation in Koirino in the Fukushima Prefecture town of Okuma is estimated to be 508.1 millisieverts per year. "It is difficult even to secure workers," said an official of the Japan Atomic Energy Agency, which has been helping with decontamination efforts. Even if the government-imposed target of reducing radiation levels by half in two years is achieved, it is far cry from 20 millisieverts -- the estimated level of radiation that is safe for local residents to return home.

(Mainichi Japan) August 27, 2011

Kan: Central storage plant planned in Fukushima

Prime Minister Naoto Kan has informed the governor of Fukushima Prefecture of a plan to build a central storage plant to temporarily manage nuclear waste, including contaminated soil.

At a meeting in Fukushima City on Saturday, Governor Yuhei Sato responded that he was troubled to hear about such a plan so suddenly.

He asked the government to take responsible action, as the plan would be extremely serious for the prefecture and relevant municipalities that have suffered greatly from the nuclear accident.

After the meeting, Kan told reporters that the government has no intention of making the plant a final facility.

He said he needed to make the request in order to pave the way to begin carrying out decontamination.

Sunday, August 28, 2011 02:15 +0900 (JST)

Experts split on how to decommission Fukushima nuclear plant

What is actually going to take place at the Fukushima No. 1 Nuclear Power Plant, where word is that the four reactors that were crippled in the Great East Japan Earthquake and tsunami will eventually be decommissioned?

The Ministry of Economy, Trade and Industry's Nuclear and Industrial Safety Agency (NISA) defines "decommissioning" as the process of removing spent fuel from reactors and dismantling all facilities. Ultimately, the site of a decommissioned reactor is meant to be reverted into a vacant lot.

In 1996, the then Japan Atomic Energy Research Institute (JAERI) -- now the Japan Atomic Energy Agency (JAEA) -- finished decommissioning its Japan Power Demonstration Reactor. The decommissioning process of the Tokai Nuclear Power Plant in the Ibaraki Prefecture village of Tokai began in 1998 and is set to end in fiscal 2020, while the No. 1 and No. 2 nuclear reactors at the Hamaoka Nuclear Power Plant in the Shizuoka Prefecture city of Omaezaki are slated for decommissioning by fiscal 2036. Around the world, only around 15 nuclear reactors have thus far been dismantled.

The standard decommissioning process entails six major steps: 1. Remove spent fuel rods, 2. Remove radioactive materials that have become affixed to reactor pipes and containers, 3. Wait for radiation levels to go down with time, 4. Dismantle reactors and other internal vessels and pipes, 5. Dismantle the reactor buildings, and 6. Make the site into a vacant lot.

"Cleaning," "waiting," and "dismantling" are the three key actions in this process. Needless to say, this all needs to be done **while simultaneously containing radioactive materials**.

In the case of the Tokai Nuclear Power Plant, the first commercial plant to undergo decommissioning, spent fuel was removed over a span of three years beginning in 1998, and was transported to Britain for reprocessing. Dismantling of the facilities began in 2001, with current efforts being made toward the dismantling of heat exchangers; workers have not yet begun to take the reactor itself apart. The entire process is expected to be an 88.5-billion-yen project involving 563,000 people.

Hitachi Ltd., which manufactures nuclear reactors, says that it "generally takes **about 30 years**" to decommission a reactor. The Hamaoka Nuclear Power Plant's No. 1 and No. 2 reactors operated by Chubu Electric Power Co. are also expected to take about 30 years before they are decommissioned.

In the case of the Fukushima No. 1 Nuclear Power Plant, meanwhile, the biggest challenge lies in how to remove the fuel, says Tadashi Inoue, a research advisor at the Central Research Institute of Electric Power Industry (CRIEPI), a foundation that conducts research on energy and environmental issues in relation to the electrical power industry. Inoue has long been engaged in research concerning nuclear fuel and reprocessing, and as a member of a special committee in the Cabinet Office's Japan Atomic Energy Commission (JAEC), is deliberating mid- to long-term technological milestones for the stricken Fukushima plant.

"But," Inoue continues, **"we must deal with rubble contaminated with radioactive materials that were scattered in the hydrogen blasts and treat the radiation-tainted water being used to cool nuclear fuel before we can go on to fuel removal."**

Currently, the Fukushima plant's operator, Tokyo Electric Power Co. (TEPCO), is desperately trying to treat the contaminated water. Huge challenges remain with regards to the contaminated rubble, as radiation levels of over 10 sieverts per hour were found near outdoor pipes on the plant grounds just the other day. Exposure to such high levels would mean death for most people.

Each step in the process toward decommissioning is complicated and requires great numbers of people. It's a race against time because the maximum amount of radiation that workers can be exposed to is 250 millisieverts.

Prefacing the following as "a personal opinion," Inoue says: "Building a car that can protect the people inside as much as possible from radioactive materials, and attaching an industrial robotic arm to the car that can be manipulated by those people could be one way to go about it."

Two types of fuel removal must take place. One is to take out the spent fuel in the containment pools, and the other is to remove the melted fuel from the reactor cores. Because the radiation levels of the water in the spent fuel pools have not shown any significant changes from before the crisis, it is believed that the spent fuel has not suffered much damage. However, removing it will require repairing and reinstalling cranes to hoist the fuel rods out.

The breached reactor core is a bigger problem. It is believed that raising water levels inside the reactor has been difficult because of a hole in the bottom of the vessel. It will be necessary to plug the hole, and continue filling the vessel with water while extracting the melted fuel. How to fill the vessel with water is still being debated. If the reactor can be filled with water, steps taken after the 1979 Three Mile

Island nuclear accident can serve as a guide because in that case, in which approximately 50 percent of the core had melted, workers were able to fill the reactor with water and remove the fuel within.

Inoue predicts that removal of spent fuel from the containment pools will begin about five years after the crisis, and about 10 years in the case of melted fuel from the reactor core. Work on the four reactors at the Fukushima plant will probably take several years.

"Unless we look at the actual reactors and take and analyze fuel samples, we can't know for sure," Inoue adds. Plus, even if workers succeed in removing the fuel, reprocessing it is an even more difficult task. **A review of processing methods and storage sites, moreover, has yet to take place.**

The Federation of Electric Power Companies of Japan (FEPC) calculated in 2007 that decommissioning one nuclear reactor costs approximately 66 billion yen. Inoue suggests, however, that the cost of decommissioning reactors after a disaster of this magnitude may be much higher.

Meanwhile, at least one expert says he doesn't believe that workers will be able to remove the melted fuel from the crippled plant.

"If there's 10 sieverts per hour of radiation outside, then the levels must be much higher closer to the reactor core," says Tadahiro Katsuta, an associate professor at Meiji University and an expert in reactor engineering and reactor policy who was once a member of an anti-nuclear non-profit organization called Citizens' Nuclear Information Center (CNIC). "The fuel has melted, and we haven't been able to cool it consistently. If work is begun five or 10 years from now when radiation levels have not yet sufficiently gone down, workers' health could be at serious risk."

Katsuta predicts that **it will probably take at least 10 years just to determine whether it is possible to remove the fuel. He adds that it could very well take 50 years before the task of dismantling the reactor and other facilities is completed.**

What Katsuta has in mind is a Chernobyl-style concrete sarcophagus, which would entail cloaking the melted tomb with massive amounts of concrete. "How could we simultaneously dismantle four reactors that have been contaminated to the extent that they have by radioactive materials?" asks Katsuta. "Japan has little experience in decommissioning reactors, and this case is quite different from standard decommissioning processes. It's not realistic to think we can revert the site back to a vacant lot. I think we should be considering options such as entombing the site with concrete or setting up a protective dome over the damaged reactor buildings.

As for decommissioning costs, Katsuta predicts the figure will not be as high as the construction cost of the reactors (300 billion to 400 billion yen per reactor) themselves, but close to it, due to the massive amounts of highly contaminated radioactive waste.

Regardless, what we face is a great unknown to all of mankind.

Above-limit cesium found at incinerators in 7 prefectures

Rice that was harvested early in Aizubange, Fukushima Prefecture, is checked for radiation in a germanium semiconductor detector in the prefectural city of Koriyama on Aug. 25. (Mainichi)

TOKYO (Kyodo) -- Incinerator dust and ash with too much radioactive cesium to allow it to be buried has been found at 42 facilities in Tokyo, Chiba, Iwate and three other prefectures as well as Fukushima, the Environment Ministry said Saturday.

The result of a survey of 469 facilities in 16 prefectures in northeastern and eastern Japan since late June was reported as a panel of experts at the ministry considers how to allow dust and ash containing over 8,000 becquerels of cesium per kilogram to be buried.

The government has already decided to allow dust and ash containing 8,000 becquerels or less of cesium to be buried in waste disposal sites only if residential houses are not built there in the future.

A worker exposed to such a level every day would still not exceed the annual limit of 1 millisievert for ordinary people.

But local governments are required to temporarily store such dust and ash at disposal sites until the panel reaches a conclusion.

The amounts detected were up to 95,300 becquerels in Fukushima, 70,800 becquerels in Chiba and 30,000 becquerels in Iwate.

Since 9,740 becquerels of cesium per kilogram was found in dust at an incineration plant in Tokyo's Edogawa Ward in June, other prefectures also covered in the ministry survey such as Gunma and Ibaraki have released similar findings.

(Mainichi Japan) August 28, 2011

Fukushima No. 4 unit explosion caused by hydrogen leak from No. 3

TOKYO (Kyodo) -- Tokyo Electric Power Co. has found evidence that the March 15 explosion at its Fukushima Daiichi nuclear power plant's No. 4 reactor unit was caused by hydrogen that had flown from the adjacent No. 3 unit, officials said recently.

When it measured on Thursday the radiation levels of filters of exhaust pipes from the No. 4 and the No. 3 unit before a common exhaust stack, the utility found evidence indicating radioactive steam and hydrogen had flown into the No. 4 reactor building, in an opposite flow from usual, the utility officials said.

The radiation was 6.7 millisieverts per hour near the junction but fell to 0.5 millisievert and 0.1 millisievert at the approach to the building, they said.

The plant operator known as TEPCO initially believed the explosion at the No. 4 unit was caused by hydrogen gas produced by the exposure of fuel stored under water in a pool in that building. But TEPCO officials said the new evidence points to the possibility, first suspected in May, that hydrogen gas had flown from the No. 3 unit as the fuel was not particularly damaged.

(Mainichi Japan) August 29, 2011

High radiation levels on land near Fukushima plant

The education and science ministry has identified land near the damaged Fukushima Daiichi nuclear plant where radiation levels are higher than IAEA-designated emergency levels.

The ministry released a map on Monday showing the contaminated land. It conducted a survey for radioactive cesium at some 2,200 locations mainly in Fukushima Prefecture in June and July.

The map shows 29.46 million bequerels of cesium on one-square-meter land in a location in Okuma Town, several hundreds meters from the nuclear plant.

The figure exceeds **the IAEA standard of 10 million bequerels per square meter under which people are required to temporarily evacuate.**

Two other monitoring spots northwest of the nuclear plant were also found contaminated with radioactive cesium exceeding the IAEA level.

In the 1986 Chernobyl disaster, people in areas contaminated with 555,000 bequerels of cesium per one square meter were required to temporarily relocate.

The latest survey has identified contaminated land outside the government's no-entry zones in Fukushima Prefecture that is similar to Chernobyl.

Monday, August 29, 2011 21:43 +0900 (JST)

Rice shipments begin in Fukushima

Rice farmers in Fukushima Prefecture have begun shipping early-harvested rice after it cleared tests for possible radioactive contamination. Rice is Japan's staple food.

The first batch of newly harvested rice was loaded onto trucks at a farm in Koriyama City on Monday.

Earlier this month, Fukushima checked radiation levels of early-harvested varieties of rice at paddies of all rice growers in the prefecture. Test results confirmed the safety of all the checked rice, although a small amount of radioactive cesium was detected in rice grown at one location.

A farmer who shipped his rice on Monday said he feels relieved as he is able to offer safe rice to consumers.

But he said **the early-harvested variety accounts for only 5 percent of his crop**, so he is still worried if he can ship other varieties, including the mainstay Koshihikari brand.

The freshly harvested rice will be available in local super markets from Tuesday.

Monday, August 29, 2011 13:06 +0900 (JST)

Map of radiation levels on farmland released

Japan's agriculture ministry has unveiled a map of radiation levels in agricultural areas. It shows **levels of radioactive cesium are higher than the government-regulated standard in some areas**.

The ministry drew up the map based on analysis of soil samples taken at 580 locations in 6 prefectures including Fukushima where the tsunami-damaged nuclear power plant is located.

The map released on Monday shows radioactive cesium exceeding the regulated level of 5,000 bequerels per kilogram in 9 locations. Vegetables and fruit are grown in the farmland.

The government has banned rice planting on farmland contaminated with radioactive cesium higher than 5,000 bequerels per kilogram, following the accident at the Fukushima Daiichi nuclear plant.

The map shows contamination of 8,571 bequerels on a field in Date City and 6,882 bequerels in Iwaki City, both in Fukushima Prefecture.

In areas where rice planting has been prohibited, including Namie Town and Iitate Village in Fukushima, the map shows radioactive cesium of over 20,000 bequerels per kilogram.

The agriculture ministry plans to increase monitoring around the highly contaminated farmland.

Monday, August 29, 2011 20:26 +0900 (JST)

No cesium detected in seawater near No.3 reactor

The operator of the Fukushima Daiichi nuclear power plant says **no radioactive cesium was detected in seawater around the No.3 reactor on Saturday. This was the first time the substance was not detected since the monitoring began.**

Cesium levels around the No.2 reactor were down slightly from those detected on the previous day.

Tokyo Electric Power Company, or TEPCO, monitors the concentration of radioactive substances in

seawater near the water intakes of the plant and offshore.

Seawater collected near the water intake of the No.2 reactor on Saturday recorded 0.077 becquerels of cesium-134 per cubic centimeter, which is 1.3 times higher than the government-set safety limit.

It also contained 0.075 becquerels of cesium-137, or 0.83 times the limit. Both figures were slightly down from the levels found on the previous day.

In April, the level of cesium-137 in seawater near the water intake of the No.2 reactor was found to be 1.1 million times the safety limit. Since then, the density has declined, and recently is leveling out.

Seawater sampled near the water intake of the No.3 reactor did not contain any cesium-134 or cesium-137.

No radioactive materials were found in seawater taken from 7 locations along the coast and offshore.

Fukushima Fallout: Worse than Hiroshima or Chernobyl?

by Gordon Edwards, August 29, 2011 - http://www.ccnr.org/Fukushima_vs_Chernobyl.html

Background:

No one has ever before experienced the extensive radioactive contamination of air, water, soil, and food that now faces the Japanese people after the Fukushima disaster.

It is important to realize that each nuclear reactor contains more than a thousand times as much radioactive material as the radioactive fallout from a Hiroshima-type atomic bomb.

The dropping of the atomic bombs on the cities of Hiroshima and Nagasaki in 1945 caused enormous destruction, brought about by the blast and by the fireball. It also caused massive radiation exposures, mainly neutron and gamma radiation, most of it delivered at the very instant of the explosion.

But the fallout in the area of the bombed cities was relatively little, because in both cases the bombs were deliberately detonated high in the air so that the concussive shock wave would do the most damage on the ground. Thus no crater was created by the blast, and most of the fallout was carried high into the atmosphere by the heat of the fireball and the burning of the cities. It became global fallout more than local fallout.

Similarly, at Chernobyl, there was an explosion followed by a very hot graphite fire that raged for days, lofting much of the radioactive fallout high into the air, and sending it across vast distances. A lot of it was deposited in Belarus and other European countries; it contaminated the sheep in Northern England and Wales for two decades. Some of it made its way across the ocean to contaminate the lichen in Northern Canada, which resulted in measurable increases of radioactive cesium in the bodies of the Inuit people who fed on the caribou that fed on the lichen.

But at Fukushima, not one but three nuclear reactors melted down -- Units 1, 2, and 3 -- as well as a spent fuel pool in Unit 4 that caught fire and spewed radioactive debris directly into the atmosphere. Because there was no fireball, no burning cities, and no burning graphite, the radioactive fallout stayed closer to the ground and contaminated everything that it came in contact with.

The local contamination at ground level is more extensive and more insidious than anything that has previously been experienced. Radioactive iodine has already done its worst, though the results will not be seen for decades in terms of thyroid cancers and developmental abnormalities caused by thyroid damage to embryos, infants and children. But the radioactive cesium and strontium and plutonium and americium and dozens of other radioactive species will be in the soil and the food and the bodies of Japanese living near the affected areas and even those further away for decades, even centuries to come.

No one truly knows the full long-term effects of chronic exposure of such a huge population to these radioactive poisons, for the degree of local radioactive contamination resulting from Fukushima is indeed unprecedented.

"Radio-phobia" rears its ugly head yet again, vis a vis Fukushima

August 30, 2011
admin

Blaming "radio-phobia" rather than radiological injuries is yet another trick in the nuclear establishment's PR tool box. Nuclear power boosters have long tried to convince victims of radioactive catastrophes that "it's all in your head." Both at Three Mile Island and Chernobyl, the nuclear power industry -- and its friends in government regulatory agencies, the PR industry, and even academia -- tried to convince the public that any ill effects were not due to physical impacts of radioactive fallout, but rather to stress and worry caused by "anti-nuclear fear mongering." [A short piece in NewScientist](#) gives this Orwellian "psy-ops" ploy "airtime" yet again, this time in the context of the Fukushima nuclear catastrophe.

Nuclear plant worker dies of acute leukemia

In this Monday, Aug. 1, 2011 photo released by Tokyo Electric Power Co. on Tuesday, Aug. 2, a worker in protective gear measures radiation levels near a duct connected to a ventilation stack between the Unit 1 and Unit 2 reactors at the crippled Fukushima Dai-ichi nuclear power plant in Okuma, Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

TOKYO (Kyodo) -- A worker in his 40s who had been engaged in recovery work at the crisis-hit Fukushima Daiichi nuclear power plant has died of acute leukemia, plant operator Tokyo Electric Power Co. said Tuesday.

Tokyo Electric said the worker's death is not linked with his work at the plant, citing results of medical examination by doctors.

The man had been exposed to 0.5 millisievert of radiation at the plant and showed no internal exposure to radiation, said the power company, known as TEPCO.

The dosage is much smaller than 5 millisieverts or higher per year -- the benchmark for recognizing a death as work-related -- TEPCO said, citing the Ministry of Health, Labor and Welfare's criteria on work-related deaths. The ministry's criteria also put the incubation period to develop symptoms of acute leukemia at one year.

TEPCO said the man had been involved with duties on radiation control at the plant for a week starting in early August. He later complained of poor health and underwent medical checkups before his death.

TEPCO said it received the report on the worker's death on Aug. 16 from one of its contractors whose subcontractor hired the worker.

The utility said it had no information on the man's work career before being engaged in the recovery work at the nuclear power plant which was crippled by the March 11 earthquake-tsunami disaster.

(Mainichi Japan) August 30, 2011

Gov't to lower Fukushima nuclear workers' radiation exposure limit

TOKYO (Kyodo) -- The government plans to lower a radiation exposure limit from 250 millisieverts to a usual level of 100 millisieverts possibly this fall for workers dealing with the Fukushima Daiichi nuclear plant crisis, a Cabinet minister said Tuesday.

"The limit must be lowered," Health, Labor and Welfare Minister Ritsuo Hosokawa told a press conference. "We may have to make a decision as soon as this fall."

The ministry raised the allowable radiation exposure limit to 250 millisieverts as an emergency measure soon after the March 11 earthquake and tsunami led to a series of catastrophic explosions and release of a massive amount of radiation.

The ministry intends to implement the exposure limit reduction after examining actual radiation exposure as crisis management efforts by plant operator Tokyo Electric Power Co. have entered the "step 2" phase of achieving a cold shutdown of the damaged reactors at the plant.

(Mainichi Japan) August 30, 2011

Radiation limit to be lowered for Fukushima staff

Japan's health ministry will restore the cumulative radiation exposure limit for emergency workers at the Fukushima Daiichi nuclear plant to the original 100 millisieverts this autumn. **The current limit is 250 millisieverts.**

The ministry raised the exposure limit soon after the nuclear accident in March to secure enough time for workers at the plant to bring the situation under control.

At a news conference on Tuesday, Health Minister Ritsuo Hosokawa said he wants to **return the legal limit to the previous level by autumn.**

The ministry says 103 workers who started at the plant just after the accident have been exposed to cumulative radiation of more than 100 millisieverts.

But it says all staff who began work from April on have been exposed to less than 100 millisieverts.

Based on the reduced exposure, the ministry has concluded that there is no longer a need to maintain the higher provisional radiation limit.

Tuesday, August 30, 2011 13:52 +0900 (JST)

34 points near Fukushima plant exceed radiation standard used for Chernobyl, map shows

A government map of soil radiation levels mainly within a 100-kilometer radius of the disaster-hit Fukushima No. 1 Nuclear Power Plant shows 34 locations with levels of cesium-137 exceeding 1.48 million becquerels per square meter, the level that was used for determining bans on living near the Chernobyl plant.

The map was released on Aug. 29 by the Ministry of Education, Culture, Sports, Science and Technology (MEXT). Cesium-137 has a half-life of around 30 years. The greatest concentration was found in the town of Okuma, which holds part of the plant, at 15.45 million becquerels per square meter. The six municipalities with levels over the Chernobyl level are Okuma, Minamisoma, Tomioka, Futaba, Namie, and Iitate.

The distribution of cesium in the soil across the 100-kilometer radius zone was very close to that calculated from air samples taken in the same areas.

"The directly measured data from this survey will be useful for decontamination work," says Takashi Nakamura, a professor emeritus of Tohoku University who was involved with the map's creation.

Three corporations and 94 organizations including universities and MEXT cooperated to collect data in June and July from around 2,200 zones, each zone two kilometers by two kilometers. For each zone, soil and grass from five freely chosen locations was collected, mixed and measured.

Also on Aug. 29, the Ministry of Agriculture, Forestry and Fisheries (MAFF) released a map showing radioactive cesium (cesium-137 and cesium-134) concentrations in agricultural land in Fukushima, Miyagi, Tochigi, Gunma, Ibaraki and Chiba prefectures. Measurements were taken at 360 locations in Fukushima and 220 locations across the other five prefectures. In 13 Fukushima municipalities including Iitate, Soma and Minamisoma, there were measurements exceeding 5,000 becquerels per kilogram of soil, which is the limit over which rice planting is forbidden.

MAFF intends to expand the survey to 3,000 locations in the future.

(Mainichi Japan) August 30, 2011

Gov't officials' role in manipulating nuclear symposiums confirmed

TOKYO (Kyodo) -- Central government officials were involved in attempts to manipulate how public opinion on nuclear power is presented at government-sponsored symposiums, a third-party panel investigating the matter said Tuesday.

According to an interim report submitted by the panel to the industry ministry the same day, officials of the government's nuclear safety agency asked utility firms to encourage people related to the utilities to attend nuclear power symposiums several years ago and to voice opinions supportive of nuclear plants.

The three "pluthermal" nuclear project symposiums were held by Kyushu Electric Power Co. in October 2005 on its Genkai power plant, Shikoku Electric Power Co. in June 2006 on its Ikata plant and Chubu Electric Power Co. in August 2007 on its Hamaoka plant.

Pluthermal power generation uses plutonium-uranium mixed oxide fuel, which contains plutonium extracted from spent fuel, in existing reactors and is an important pillar of Japan's nuclear program.

"It's very regrettable that the government's involvement in the pluthermal symposiums linked to the Genkai, Ikata and Hamaoka nuclear power plants was confirmed," Economy, Trade and Industry Minister Banri Kaieda said in a statement.

Panel head Takashi Oizumi, a lawyer who once headed the Osaka High Public Prosecutors Office, said at a press conference that government officials' involvement is also suspected in five more cases related to similar events held by Kyushu Electric and Tohoku Electric Power Co., and that the panel will investigate the matter further.

The panel consisting of four legal experts aims to compile its final report by the end of September.

Nuclear and Industrial Safety Agency chief Hiroyuki Fukano offered an apology for the agency officials' involvement at a press conference, saying, "I apologize to the citizens and those concerned."

"Essentially, (the agency) should have a culture in which officials act rightly and fairly, but it was not the case," he said.

The report said a Shikoku Electric official in charge of the symposium in question produced a memo saying that a nuclear safety agency official told the utility employee that the key to the symposium's success was securing enough attendees and suppressing the views of people opposed to nuclear power projects.

The panel was set up earlier this month by the industry ministry, which has the agency under its wing, to investigate allegations that the agency asked utilities to dress up public symposiums on atomic energy to make local communities appear supportive of nuclear power plants.

The allegations emerged following the revelation of a scandal in which senior officials of Kyushu Electric Power Co. tried to manipulate public opinion on its Genkai nuclear plant in its favor in the wake of the Fukushima nuclear plant accident.

State-sponsored symposiums on nuclear power have been held across the country to enable local leaders to consider the operations of nuclear power plants in their jurisdictions.

(Mainichi Japan) August 31, 2011

80% of Japan's reactors out of service

Another nuclear reactor in Japan will soon be shut down for regular inspections, leaving nearly 80 percent of the country's reactors out of service.

Kyushu Electric Power Company says it will begin work on Wednesday to halt operations at the No.2 reactor at the Sendai nuclear power plant. The reactor will be shut down by Thursday morning.

The utility wants to restart the reactor in 4 months, after exchanging fuel rods and making detailed checkups on turbines.

But it is unclear when the company can restart the reactor, as well as another one at the plant which remains out of service although regular checkups have been completed.

After the Fukushima accident, underhanded practices of power companies and the government have come to light.

Kyushu Electric and other utilities reportedly tried to influence government-sponsored town meetings in favor of nuclear energy, and mobilized people behind the scenes to win local approval for nuclear power generation.

Such practices have spurred public distrust in utilities and government oversight of the nuclear industry.

After the Sendai No.2 reactor is shut down, 42 nuclear reactors among 54 in Japan will be out of service.

Wednesday, August 31, 2011 11:17 +0900 (JST)

TEPCO finds possibly active faults near Fukushima

Tokyo Electric Power Company suspects there are 5 active faults near the Fukushima Daiichi nuclear power plant that could affect the crippled plant if they cause a tremor.

TEPCO made the discovery after the Japanese government requested utilities and nuclear agencies to reexamine faults around nuclear plants.

The directive followed a strong earthquake on April 11th from a fault thought to be inactive, 50 kilometers from the Fukushima plant.

TEPCO said on Tuesday that geological deformations were observed for the first time at 5 faults, suggesting they are active.

The utility will continue drilling to investigate the conditions, though the firm believes any tremors would be within the quake-resistance standard.

Besides TEPCO, two nuclear agencies reported 9 faults near their nuclear facilities in Ibaraki Prefecture that could be active.

Wednesday, August 31, 2011 06:16 +0900 (JST)

14 locations near nuclear plants could become active faults, agency warns

Some 14 locations near nuclear facilities in Japan have been found to have the possibility of turning into active faults in the future, the Nuclear and Industrial Safety Agency (NISA) has announced.

NISA said on Aug. 30 that it has confirmed a total of 14 faults and other locations whose possibility of turning into active faults in the future cannot be ruled out near the Fukushima No. 1 and No. 2 nuclear power plants and Japan Atomic Power Co.'s Tokai No. 2 Power Station in Ibaraki Prefecture.

NISA had instructed plant operators to re-evaluate those locations after aftershocks following the March 11 Great East Japan Earthquake triggered the Yunotake fault in Iwaki, Fukushima Prefecture, to slip even though it had been believed to be inactive.

As a result of the re-evaluation, it emerged that five locations near the Fukushima nuclear plant, including the Yunotake fault, have a possibility of moving in the future due to crustal twists and increased seismic activity in the wake of the March 11 quake. A total of nine locations near the Tokai No. 2 Power Station and the Japan Atomic Energy Agency's Tokai nuclear fuel reprocessing plant were also revaluated.

Even if any of these faults and other locations ever slipped, the intensity of tremors would be within the scope of the assumption, and the existing plants have no problem in terms of their quake resistance, according to NISA.

NISA will put together the re-evaluation results shortly and submit them to the Nuclear Safety Commission of Japan.

Paddy decontamination method tested

Japanese researchers have begun testing a method for removing radioactive substances from paddies in an evacuation zone near the Fukushima Daiichi nuclear power plant.

The National Agriculture and Food Research organization is conducting the test in Iitate Village, more than 30 kilometers northwest of the troubled plant, at the request of the government.

On Tuesday, the researchers used a power shovel at a paddy to break up about 3 centimeters of surface soil that had been hardened with a solidifier. The soil was then collected using a vacuum hose.

The researchers are to check the remaining soil for radiation to determine the effectiveness of the method.

Before the test, the level of radioactivity at the paddy was 12,000 becquerels per kilogram of soil, or more than double the limit at which planting is prohibited.

The head of the researchers said they will analyze data from the test to determine whether the method can be used to help resume farming in the area.

Tuesday, August 30, 2011 18:22 +0900 (JST)

Hakodate mayor seeks continued freeze on Aomori nuclear power plant

Hakodate Mayor Toshiki Kudo visited a nuclear power plant under construction in Oma, Aomori Prefecture, on Aug. 30 and sought an indefinite freeze on the project, just 23 kilometers away from the heart of the southwestern Hokkaido city.

"It is so close to Hakodate, and there is nothing to shield (nuclear radiation) if an accident happens," Kudo said of the Oma Nuclear Power Plant with a planned output capacity of 1.38 million kilowatts.

J-Power, the nation's leading electricity wholesaler, is building the nuclear power plant, which will use plutonium-uranium mixed oxide, or MOX, fuel.

The company had expected the plant to go on stream in November 2014. But the March 11 earthquake and tsunami and the resulting Fukushima nuclear crisis forced J-Power to suspend the project, which had been 37 percent complete.

Accompanied by Ko Notoya, speaker of the Hakodate City Assembly, Mayor Kudo was briefed by J-Power officials on a three-meter-tall levee and emergency generators. He later stood on an elevated spot and checked the location of buildings to house a nuclear reactor and turbines.

The mayor later told reporters, "They explained safety measures, but I was not convinced. It is also problematic that a site to eventually process nuclear waste has not been decided."

Before his inspection tour, Kudo held talks with Oma Mayor Mitsuharu Kanazawa and Hideo Ishido, speaker of the Oma Town Assembly, at the town hall and delivered a written statement requesting an indefinite freeze on the nuclear power plant project that the Hakodate assembly adopted in July.

Ishido said after the talks, "We understand Hakodate's concerns but most of the 2,000 workers left after construction halted. Our town assembly wants J-Power to resume construction (of the nuclear power plant)."

(Mainichi Japan) August 31, 2011

Fukushima nuke plant workers irradiated on job ignored alarm: TEPCO

Two workers exposed to high doses of beta radiation at the crisis-stricken Fukushima No. 1 Nuclear Power Plant on Aug. 28 were ignoring their dosimeter readings, plant operator Tokyo Electric Power Co. (TEPCO) announced on Aug. 30.

The two men were both blasted with beta radiation while they and one other worker were replacing filters on a water decontamination system at the plant -- a task that requires pulling components out of the water. TEPCO stated that they ignored the radiation count on their dosimeters and continued to do the filter replacement despite absorbing radiation doses of 23.4 and 17.1 millisieverts respectively, exceeding the 15-millisievert limit for the operation.

According to TEPCO, the men's radiation alarms sounded when their doses exceeded the 15-millisievert maximum, but they decided to complete the task with the help of the third worker as they had very little left to do. The utility also said the men's radiation control manager was not present at the time. Testing revealed the third worker absorbed a 1.1-millisievert dose.

Beta rays are a type of radiation that can penetrate the skin and enter the body, and total exposure is legally limited to 1,000 millisieverts.

(Mainichi Japan) August 31, 2011

2 workers showered with highly radioactive water

Tokyo Electric Power Company says 2 male workers at its troubled Fukushima Daiichi nuclear power plant were showered with highly radioactive water **by mistake**.

The accident occurred on Wednesday morning.

The two subcontracting workers were suddenly splashed with water leaking from a container whose valve was not shut. The container was **part of the contaminated water processing system**.

TEPCO says one of the 2 workers was found to be exposed to 0.16 millisieverts of radiation, which is higher than the safety limit, and was decontaminated.

The other, who was wearing a raincoat, was exposed to 0.14 millisieverts of radiation, a slightly smaller dose than the other man.

The utility says that the 2 workers did not complain of symptoms such as burns and they had no internal radiation exposure.

TEPCO is investigating how the accident occurred.

Last Sunday, 2 TEPCO workers at the plant were exposed to radiation by mistake while they were

replacing parts of the contaminated water processing system, which is key to bringing the crippled reactors under control.

Wednesday, August 31, 2011 22:23 +0900 (JST)

TEPCO presents plan to extract melted rods

Tokyo Electric Power Company, or TEPCO, has announced a plan to extract melted nuclear fuel rods at the crippled Fukushima Daiichi nuclear power plant.

TEPCO presented the 9-stage plan on Wednesday to an expert panel of the Atomic Energy Commission, which is discussing a process to decommission the plant's reactors.

The first 3 stages of TEPCO's plan are devoted to removing radioactive materials from the reactors' buildings to repair containment vessels and stop water leaks.

The utility plans to then put water in the vessels and take pictures to determine the amount of nuclear fuel that has leaked from the reactors.

In the final stage, the company plans to fill the vessels with water and use robots to extract the rods.

Extraction of fuel rods that have leaked outside of reactors has never been performed at any nuclear plant.

TEPCO faces the tough challenges of coping with high levels of radiation and developing highly efficient robots.

Wednesday, August 31, 2011 20:38 +0900 (JST)

SEPTEMBRE 2011

(Mainichi Japan) September 1, 2011

TEPCO eyes removing melted fuel after filling reactors with water

TOKYO (Kyodo) -- Tokyo Electric Power Co. said Wednesday that it plans to take out the melted nuclear fuel from inside the crippled reactors at the Fukushima Daiichi power plant after repairing the reactor containers and filling them up with water.

But the plant operator did not go further into details, only saying that the plan, unveiled during a meeting of a government panel on nuclear energy policy, is **just "an image at the current moment."**

The process is expected to start with the removal of radioactive substances inside the plant's buildings housing the reactors, which would be followed by repair work on the primary containment vessels.

Workers are then expected to fill each primary containment vessel with water to a level above the fuel and open the lid of the inner pressure vessel holding the fuel.

Flooding the primary containment vessel with water is a method Tokyo Electric tried to employ in the past as part of efforts to stably cool the fuel, although it gave up doing so because one container appeared to have been leaking massive amounts of water injected into the reactor.

The utility known as TEPCO said it believes that **flooding the container is necessary before removing the fuel because water would help block the radiation so that workers will be able to pinpoint the position of the melted fuel.**

The process would take place without stopping the water currently being injected into the crippled reactor cores under a water circulation system created after the nuclear crisis, TEPCO said.

But the company also noted that it may have to seek alternatives because an "advanced technological development" is likely to be required to carry out the planned procedures.

On March 11, a magnitude 9.0 earthquake and tsunami waves led the six-reactor nuclear complex to lose nearly all of its power sources and caused the cooling functions of the reactors and spent nuclear fuel pools at the Nos. 1 to 4 units to fail.

The Nos. 1 to 3 reactor cores are assumed to have suffered meltdowns in the early days of the crisis, possibly damaging the bottom of each reactor pressure vessel and partially accumulating in the outer primary container.

Groundwater around Fukushima nuke plant to be protected by underground steel barrier

Construction of an underground barrier at the stricken Fukushima No. 1 nuclear plant to prevent leaking radioactive materials from reaching ground water **will begin this year and be completed in about two years**, plans released on Aug. 31 revealed.

The plans, announced by plant operator Tokyo Electric Power Co. (TEPCO), include use of a workboat and a temporary pier by the plant to speed up construction. According to the utility, the barrier will be built of between 600 and 700 22-meter-long steel sheet piles driven into the ground and stretch some 800 meters. The approximate 10-meter space between the steel barrier and the existing dike will also be filled with concrete.

Simulations conducted using benign substances that mimic the properties of radioactive materials showed the barrier at the coastal plant would stop the dangerous materials from reaching the ocean.

The barrier is expected to last for 30 years. [et après ???]

The barriers are specifically intended to prevent contaminated water in buildings housing reactors 1 to 4 and their turbine buildings from seeping into the local ground water. **TEPCO will continue to monitor ground water conditions both during and after the barrier's construction.**

(Mainichi Japan) September 1, 2011

Rough road ahead for work to decommission Fukushima nuclear reactors

Tokyo Electric Power Co. (TEPCO) unveiled a plan to decommission crippled nuclear reactors at the Fukushima No. 1 Nuclear Power Plant in line with the way the 1979 Three Mile Island accident was handled, but the Fukushima case would pose difficult challenges for the crucial mission.

Following the example of the case of the Three Mile Island crisis, TEPCO, the operator of the Fukushima nuclear plant, plans to fill containment vessels with water and remove melted nuclear fuel. But in the case of the Fukushima nuclear power plant, the containment vessels were damaged, and therefore the utility had abandoned its plan to fill them with water. The decommissioning task involves tough challenges including work to identify damaged parts, stop water leaks and remove crumbled fuel under the highly radioactive environment.

At an experts' meeting of the government's Nuclear Safety Commission held after receiving the report from the utility, Hajime Asama, a University of Tokyo professor, said, "It will require various remote-control equipment to do such things as decontaminating, as well as inspecting and repairing inside of the nuclear reactors. Japan has advanced robot technology, but there are many uncharted areas, and therefore it is difficult to develop technology unless we bring together the wisdom of the people." Kazuhiro Matsumura, vice president of Japan Nuclear Fuel Ltd. said, **"We must take into account the fact that it takes far more time than usual to do the work under the highly-radioactive environment."**

The experts' taskforce is to work out and release a roadmap for reactor decommissioning by mid-January next year. Koji Okamoto, professor of nuclear engineering at the University of Tokyo, said, **"In order to decommission the reactors, we must identify the places of water leaks in the containment vessels and seal them and fill them with water and shield radiation. To that end, we must prepare maps of contamination of nuclear reactors and remove radioactive substances."** TEPCO did not disclose a timeframe for removing nuclear fuel, but Okamoto said, **"It will probably take at least 10 years."** [just to remove the fuel]

Radioactive ash to be solidified with cement under gov't plan

Ash left after the incineration of radioactive earthquake and tsunami debris should be **solidified with cement and stored at a waterproof disposal site**, according to a government notification sent to municipalities on Aug. 31.

The Environment Ministry notification applies to **ash with radiation levels of between 8,000 and 100,000 becquerels** -- a byproduct of incinerating disaster debris contaminated during the ongoing Fukushima nuclear crisis -- and stored by municipal governments at temporary disposal sites.

The ministry move comes as temporary disposal facilities in municipalities with no permanent means to deal with the material have begun to fill up, and appears aimed at encouraging final disposal measures. While the disposal process may take time, the ministry attempted to reassure local governments by telling them "the costs will ultimately be borne by (plant operator) Tokyo Electric Power Co. The ministry hopes to deal with this issue without adding any further load to local governments."

Under the proposed disposal method, **sites in soil layers that absorb cesium easily would be lined with 50-centimeter-thick waterproof sheeting to prevent the toxic ash from contaminating fresh water sources. The radioactive ash solidified with cement would then be poured in.**

To further guard against radioactive materials in the ash from getting into the water table, the notice also called on municipalities to dispose of the ash solidified with cement in isolated soil layers like clay where possible, encase the ash in concrete containers or build roofs over the disposal sites.

The ministry notice furthermore opened up the **possibility of dealing with the toxic ash at isolated toxic heavy metal disposal sites**. After the sites were filled, they would be buried, and long-term soil and atmosphere monitoring implemented.

(Mainichi Japan) September 1, 2011

Researchers develop cheap, easy method for cesium-tainted soil cleanup

Scientists at a national research institute have announced the development of technology to extract nearly all radioactive cesium from contaminated soil.

The technology, revealed on Aug. 31 by the National Institute of Advanced Industrial Science and Technology (AIST), involves **mixing the contaminated soil with a low-acidity solution**. The solution draws out the cesium, which is then taken up by a granulated pigment lining the solution container.

Radioactive substance-contaminated soil has become a major issue in the ongoing Fukushima nuclear crisis, and the AIST researchers believe their new technique could reduce total radioactive waste to 1/150th of the volume it would be without the separation procedure.

The research group believed that if non-radioactive cesium could be separated from soil collected in Iitate, Fukushima Prefecture -- part of the evacuation zone around the stricken plant -- then the same technique ought to work for the radioactive version of the element.

The group began by mixing soil containing non-radioactive cesium with a low-concentration nitric acid solution. They put the mix in a pressure vessel and heated it at 200 degrees Celsius for 45 minutes, after which the soil was 100 percent cesium-free. The same process conducted at 100 degrees Celsius reduced Cesium levels by 60 percent. The researchers said the nitric acid solution can be reused.

In the second phase of the experiment, the researchers sought to **clean the cesium out of the nitric acid solution by introducing a Prussian blue pigment that only binds to cesium ions. They lined the sides of a cylindrical container with the pigment -- each granule measuring 10 nanometers in diameter -- and passed the solution through it twice. Afterwards, the solution was entirely free of cesium.**

"We can do this process without damaging the soil, and absorb all the cesium with the pigment," said Toru Kawamoto, head of AIST's green technology research group. "It's also cheap. We'd like to cooperate with the private sector to conduct substantive experiments."

(Mainichi Japan) September 1, 2011

More radiation exposure at Fukushima plant

Japan's nuclear safety agency has instructed Tokyo Electric Power Company, the operator of the Fukushima Daiichi nuclear power station, to improve safety measures for workers at the crippled plant.

The Nuclear and Industrial Safety Agency said **another worker at the power plant was exposed to radiation while working on a treatment system for contaminated water on Wednesday.**

The government agency said the male subcontractor was sprayed with radioactive water. It noted the water was cleaned off him after the man finished taking a radiation test.

It added the total amount of radiation which the man was exposed to during the shift was below the limit, and that it did not affect his health.

Earlier the same day, 2 other workers were showered with radioactive water while working on a contaminated water processing system.

On Sunday, 2 workers from the power company were exposed to beta rays, which are another type of radiation. The incident revealed that the utility had not set exposure limits for beta rays.

The agency instructed TEPCO to improve safety measures, saying the company failed to make use of past experiences with radiation exposure. It also said the utility company was late in reporting the latest incident.

Radiation readings in evacuation zones released

The government has released the results of detailed radiation measurements in evacuation zones around the crippled Fukushima Daiichi nuclear power plant.

The government measured radiation levels at 2,696 locations inside the 20-kilometer no-entry zone and adjacent evacuation zones in July and August. The measurements, mainly at schools and parks, are being displayed on maps on a government website.

Radiation was the highest at a location in Okuma Town, Fukushima Prefecture, about one kilometer from the plant. The level there was 139 microsieverts per hour, which translates into more than 700 millisieverts per year.

Areas with radiation exceeding 19 microsieverts per hour extended as far as 32 kilometers northwest of the plant. This figure translates into more than 100 millisieverts per year.

Along coastal areas about 3 kilometers north of the plant, radiation levels were less than one microsievert per hour.

The government will use the data to create plans for removing radioactive substances.

Friday, September 02, 2011 06:38 +0900 (JST)

Gov't releases most detailed maps yet of radiation around Fukushima plant

A government map displaying radiation levels in the area around the Fukushima No. 1 Nuclear Power Plant. An English version can be found on the page linked below.

The Japanese government has released new maps of radiation around the Fukushima No. 1 Nuclear Power Plant, the most detailed yet.

The maps show radiation levels in the 20-kilometer no-entry zone around the plant, as well as areas outside that zone that were ordered evacuated. Radiation levels are given for one centimeter and one meter aboveground for 2,696 locations, generally one location for every 500 by 500 meters.

Some very high radiation levels were recorded, the highest of which was 139 microsieverts per hour at one meter above the ground in the town of Okuma, just south of the plant. The highest level at one centimeter above the ground was 368 microsieverts per hour in Futaba, just north of the plant.

According to the maps, radiation levels of 19 microsieverts per hour or higher were detected between the plant and four to five kilometers to the south, west and northwest of the plant.

Meanwhile, in the town of Namie, the central part of the evacuated area outside the 20-km no-entry zone, high levels including 41.3 microsieverts per hour were recorded at one meter above the ground and 105 microsieverts at one centimeter above the ground.

Disaster drills held at Hamaoka nuke power plant

Workers at a suspended nuclear power plant in central Japan have held a practice drill for a possible huge earthquake and tsunami.

The emergency drill was held at Chubu Electric Power Company's Hamaoka plant on Thursday, the 88th anniversary of the Great Kanto Earthquake.

The plant on the Pacific Ocean has been suspended by the government, following the crippling of the Fukushima Daiichi nuclear power plant by the March 11th quake and tsunami.

1,000 workers took part in the drill, which assumed that the plant had lost all external power after being struck by a tsunami triggered by a quake of 6-plus on the Japanese scale of 0 to 7.

They simulated restoring power to a reactor building by connecting a 150-meter-long cable to a back-up generator installed outside.

A senior official with the utility said the drill helped confirm the effectiveness of a back-up plan to shut

down reactors at low temperatures without exposing fuels in a major earthquake.

Kanji Nishida added that the utility is considering joint drills with the local administration and residents, to provide them peace of mind.

Max 368 Microsieverts of Radiation Detected in No-Go Zone

<http://jen.jiji.com/jc/eng?g=eco&k=2011090100941>

Tokyo, Sept. 1 (Jiji Press)--The maximum radiation level stood at nearly 370 microsieverts per hour in the 20-kilometer no-go zone around the crippled Fukushima No. 1 nuclear power plant, a radiation map based on a government survey showed Thursday.

But **there was no clear correlation between the radiation level and the distance from the plant**, according to the results of the survey conducted at 2,696 locations in July and August by a government team to support nuclear crisis-affected people.

The radiation map, which covers the no-go zone and scheduled evacuation areas outside the zone, shows **the highest dose of 368 microsieverts per hour on a road in Futaba, a town located within the 20-kilometer zone.**

In the scheduled evacuation areas, where residents were asked to leave, up to 105 microsieverts of radiation was monitored, on a road in Namie.

But in areas 2 to 3 kilometers north of the plant, radiation levels rather drop below one microsievert, the team said, adding nuclear fallout spread to the northwest of the plant.

(2011/09/01-23:24)

Quake risk to U.S. reactors greater than thought

Dina Cappiello, Jeff Donn, Associated Press

Friday, September 2, 2011

Washington -- <http://www.sfgate.com/cgi-bin/article.cgi?f=/c/a/2011/09/01/MNLM1KV7P8.DTL>

The risk that an earthquake would cause a severe accident at a U.S. nuclear plant is greater than previously thought, **24 times as high in one case**, according to an Associated Press analysis of preliminary government data. **The nation's nuclear regulator believes a quarter of America's reactors may need modifications to make them safer.**

The threat came into sharp focus last week, when shaking from the largest earthquake to hit Virginia in 117 years appeared to exceed what the North Anna nuclear power plant northwest of Richmond was built to sustain.

The two North Anna reactors are among 27 in the eastern and central United States that a preliminary Nuclear Regulatory Commission review has said may need upgrades because those plants are more likely to get hit with an earthquake larger than the one their design was based on.

Just how many nuclear power plants are more vulnerable won't be determined until all operators recalculate their seismic risk based on new assessments by geologists, something the agency plans to request later this year. The NRC on Thursday issued a draft of that request for public comment.

The NRC and the industry say reactors are safe as they are, for now. **But e-mails in an 11,000-page records request by AP show that NRC experts were worried privately this year that plants needed stronger safeguards.**

Federal scientists update seismic assessments every five to six years to revise building codes for some structures. But no similar system is in place for all but two of the nation's 104 reactors. The exception is Diablo Canyon in California, which has been required to review the risk of an earthquake since 1985.

Radioactive rice rumors rampant among Kansai region consumers

More than 40 percent of married women in the Kansai region are reluctant to buy newly-harvested rice grown near the troubled Fukushima No. 1 nuclear plant, according to a recent survey.

The survey -- conducted in late August by University of Tsukuba assistant professor Kiyokazu Ujiie -- indicated that **contamination fears held sway even in cases where no radiation had been detected in the rice.**

"In light of the attitudes of consumers, in order to reduce the economic impact on producers, measures should be taken swiftly," said one expert of the survey results.

A total of 2,089 married women aged 20 to 69 in the Osaka and Tokyo areas were asked how much they would be willing to pay for a 5 kilogram of rice harvested near the Fukushima nuclear plant on the one hand, versus a 5 kilogram of rice from a different region on the other. The first option was divided into five categories: 1) radiation not detected; 2) less than one-hundredth of the government-imposed limit of 500 becquerels per kilogram detected; 3) less than one-tenth of the government-imposed limit; 4) one-half of the limit; and 5) less than the limit.

Some 44.7 percent of respondents in the Kansai region and 34.9 percent in the Kanto region said they would not buy rice harvested near the Fukushima plant at any price, even if radioactive contamination had not been detected. The survey also showed 52.9 percent of respondents in the Kanto region, and 60.4 percent of those in the Kansai region, were reluctant to buy rice containing radiation less than one-tenth of the government-imposed limit.

In the Kanto region, meanwhile, 28.9 percent of the respondents said they would buy Fukushima rice for the same price or more than rice from a different region if no radiation was detected. Even if levels of radiation close to the government-imposed limit of 500 becquerels were detected in the grain, 31.3 percent of Kanto region respondents said they would buy it if it was cheaper than that grown in a different area.

"Regardless of whether the government-imposed limit is a safe level, obviously isn't reassuring consumers. Damage caused by harmful rumors are severe particularly in the Kansai region, which is far away from the disaster-stricken areas," said Ujiie. Noting that the lower the radiation detected in the rice, the more respondents would buy the rice, he said, "If results of proper inspections are clearly shown, the rice could be sold for higher prices. **Economic damage can be reduced by giving consumers details of the degree of contamination.**" **[provided you can trust the info on radiation]**

PM's office failed to use data predicting Fukushima power loss, meltdowns

In the hours after the March 11 earthquake and tsunami, the Prime Minister's Office failed to take advantage of up-to-date analysis of the Fukushima No. 1 nuclear plant that projected both power failures and subsequent core meltdowns, according to the Nuclear and Industrial Safety Agency (NISA).

NISA released the results of analysis on the Fukushima nuclear reactors using the Emergency Report Support System (ERSS) on Sept. 2 -- about six months after the analysis was conducted right after the magnitude-9 earthquake struck. The analysis predicted the loss of power and subsequent nuclear meltdowns at the No. 1, 2 and 3 reactors at the plant before they occurred.

NISA sent the analysis on the No. 2 and 3 reactors to the Prime Minister's Office, but the office did not use the information either to help plot containment measures or to initiate a swift evacuation of local communities. The agency did not send the results of the No. 1 reactor analysis.

According to NISA, the Japan Nuclear Energy Safety Organization (JNES), which developed the ERSS, activated the system just after the quake. Based on the assumption of a complete loss of power at the plant, JNES predicted how the water levels, pressure and temperatures would change at the No. 1, 2 and 3 reactors.

The JNES sent the data on the No. 2 reactor to NISA around 9:30 p.m. on March 11. Based on the data, NISA officials projected a chain of events remarkably true to those that were to unfold at the plant, such as, "At 22:50, reactor cores will be exposed; At 24:50, fuel meltdown." NISA handed the predictions to the Prime Minister's Office at around 10:45 p.m. on March 11 and again shortly after midnight. NISA sent the data on the No. 3 reactor to the Prime Minister's Office about 20 minutes after receiving it from JNES around 6:30 a.m. on March 13.

However, the government did not use the data in its disaster response measures. Yoshinori Moriyama, NISA deputy director-general for nuclear accident measures, told a news conference on Sept. 2, "The data were not used because they were not based on facts."

Based on assumed amounts of radioactive substances inferred from the predictions for the No. 1 reactor, NISA also projected the diffusion of nuclear substances using a system known as SPEEDI, or the System for Prediction of Environmental Emergency Dose Information. The agency did not, however, release the predictions immediately, and were in the end not used at all. NISA had previously said that SPEEDI was not functioning after the quake because of a complete loss of power.

(Mainichi Japan) September 3, 2011

UN: North Korea nuke equipment from black market

VIENNA (AP) -- A report from the U.N. nuclear agency has strengthened suspicions that -- like Iran -- North Korea turned to black market suppliers to set up a uranium enrichment plant revealed only last year.

The International Atomic Energy Agency report says the layout of equipment and other details observed by a visiting U.S. group were "broadly consistent" with designs sold by a "clandestine supply network."

The confidential report made available to The Associated Press on Friday seems to allude to the black market suppliers led by Pakistani scientist Abdul Qadeer Khan. That group provided Iran with the backbone of what was a clandestine nuclear program before it was revealed eight years ago.

Khan was the main supplier of centrifuges used to enrich uranium before his operation was disrupted in 2003. Enrichment can create both reactor fuel of the fissile core of nuclear weapons.

The agency report said the plant was set up after IAEA inspectors were ordered to leave in April 2009, when five-nation talks with the North broke down and Pyongyang restarted its nuclear program.

Unless the purchases were recent and from previously unknown suppliers, that would indicate that the centrifuges were bought before the Khan network was dismantled and were in storage until two years ago.

The North tested nuclear devices in 2006 and 2009 based on plutonium, another fissile source. It denied U.S. assessments that it had a secret uranium enrichment program until Nov. 12, when it allowed a small group led by American scientist Siegfried Hecker to inspect the facility.

Hecker subsequently informed the U.S. government of what he saw, including a sophisticated enrichment facility that he said included hundreds of newly installed centrifuges.

The IAEA, which said it interviewed Hecker, said Friday the enrichment plant contained about 2,000 centrifuges and the North Koreans told the visitors that the machines operating and configured to produce low-enriched uranium, used for reactor fuel.

Beyond the centrifuges, the agency said it has information suggesting that **other technology and know-how needed for enrichment were purchased by the North from the same black market network.**

The IAEA report was prepared for a board meeting starting Sept. 12 that will discuss Iran, North Korea, Syria and other potential proliferation concerns.

Both Iran and North Korea are under U.N. Security Council sanctions -- the North for its nuclear and missile tests, and Iran primarily for refusing to stop enrichment despite concerns that it could turn the program toward making weapons.

(Mainichi Japan) September 3, 2011

Another Japanese reactor stops for regular checks

One of the reactors at a nuclear power plant in western Japan has been shut down for regular inspections. About 80 percent of the country's nuclear reactors are now out of operation.

Shikoku Electric Power Company halted the No. 1 reactor at the Ikata nuclear plant in Ehime Prefecture early on Sunday for inspections expected to last 3 months.

The operation of the No. 3 reactor of the plant is also down, although regular checks have been completed. The utility must conduct a stress test which the government requires for all suspended reactors before they can be restarted.

The Ehime prefectural government says it will decide whether to approve the resumption of operations after the results of the safety test come out.

The utility says that if the No. 3 reactor does not resume operations, power supplies will be very tight in winter when electricity demand is high.

It is considering restarting a thermal plant which has long been out of use.

43 of the country's 54 reactors are now shut down. It is not known when any of them can resume operations.

Sunday, September 04, 2011 09:02 +0900 (JST)

Cesium beyond limit found in Chiba, Saitama tea

The Japanese health ministry says radioactive cesium exceeding the government's safety limit has been detected in tea leaves in Chiba and Saitama prefectures, near Tokyo.

This is the ministry's first discovery of radioactive substances beyond the legal limit since it began unannounced tests of food products last month.

The tests were started in order to verify local government data using different numbers and kinds of

food samples.

The ministry says the leaves of one type of tea from Chiba Prefecture contained 2,720 becquerels of radioactive cesium per kilogram, more than 5 times the safety limit.

Meanwhile, a maximum level of 1,530 becquerels per kilogram was detected in 3 kinds of tea leaves from Saitama Prefecture.

The prefectural governments of Chiba and Saitama say they will investigate where the teas were grown and how much has made its way to market.

They say they will order tea producers to recall their product, if necessary.

Saturday, September 03, 2011 22:23 +0900 (JST)

Nuclear minister eyes standards for reactors' lifespan

TOKYO (Kyodo) -- Goshi Hosono, a minister tasked with handling the country's nuclear crisis, said Sunday that the government needs to set definitions and standards for how long existing nuclear power reactors should be allowed to operate before they are decommissioned.

Hosono, who doubles as environment minister, told a group media interview that a new nuclear safety agency to be created to enforce greater supervision over the country's nuclear power plants will be closely involved in decommissioning.

"We can't extend (the reactors' lifespan) by looking sideways at electric power companies' business but must create a situation where we can make decisions scientifically," Hosono said.

While nuclear reactors are designed to run for between 30 and 40 years, there is no legal rule concerning their lifespan. Electric power companies have taken the view that reactors can be operated for as long as 60 years if properly managed.

On Friday, Yoshihiko Noda said at his first news conference as prime minister that the country will shut down reactors at the end of their lifespan one by one, though without specifying what their lifespan would be.

In the interview, Hosono said it is "not necessarily scientific" to set a numerical cutoff line for nuclear power reactors, noting that they are of different types and that natural disaster scenarios differ depending on where they are located.

But "40 years may possibly be a line," he said, adding that one criterion would be the degree to which a reactor could withstand a worst-case earthquake or tsunami.

(Mainichi Japan) September 5, 2011

Fukushima Pref. shows how it tests rice for radioactive matter

FUKUSHIMA (Kyodo) -- The Fukushima prefectural government laid open Monday how it tests local rice for radioactive substances, showing to the media the cropping of sample plants for preliminary tests on brown rice at a paddy field in the town of Tanagura.

The tests of preharvest rice in 48 of the prefecture's 59 municipalities are designed to identify areas that require intensive examinations in postharvest tests, it said. The remaining 11 municipalities are without crops due to their locations inside the no-go zone around the crisis-hit Fukushima Daiichi nuclear power plant and other affected areas.

The initial tests cover unprocessed rice from about five plants each from five spots per paddy field. Municipalities with rice contaminated with more than 200 bequerels of radioactive cesium per kilogram will have more samples tested than others after harvesting, it said.

The prefecture has so far found no rice with cesium readings above the **provisional limit of 500 bequerels per kilogram of brown rice** in tests of early rice at about 200 locations, and has hence allowed shipments.

(Mainichi Japan) September 5, 2011

Nuclear troubleshooter Hosono cites need for temporary storage facility at Fukushima

New Environment Minister Goshi Hosono, who was retained as nuclear disaster minister under a new Cabinet launched Sept. 2, said in a recent interview that major problems facing the Environment Ministry include decontamination efforts, radioactive waste and the creation of a nuclear power safety agency.

"On the other hand, there are wide-ranging issues such as environmental pollution, steps to address global warming and biodiversity," he said on Sept. 4. "These issues are important for the international community and I want to tackle them in cooperation" with top deputies.

"What I want to do the most is to decontaminate" radiation-tainted areas around the crippled Fukushima No. 1 Nuclear Power Plant, Hosono stressed. Such contaminated soil and debris have to be temporarily kept in cities, towns and villages involved, according to Hosono.

"But in reality, temporarily keeping the soil and debris there is very difficult, so we have no choice but to ask Fukushima Prefecture to set up a temporary storage facility within the prefecture to safely store the waste," he said.

Hosono said the government of Prime Minister Yoshihiko Noda will not unilaterally make a decision on the issue but will reach a decision on what kind of facility and when and where such a temporary facility will be built in consultation with local governments concerned.

He also stressed the need to develop technology to reduce radioactive waste and to move it out of Fukushima Prefecture. There is a large amount of heavily contaminated rubble at the nuclear power plant and some of the rubble probably needs to be dealt with on site, he added.

The minister acknowledged that some evacuees cannot return home for extended periods of time due to the presence of high-level radioactive materials in their communities.

Workers spread lining sheets in a huge trench dug to bury radiation-contaminated topsoil collected from the ground of Yasawa Elementary School and Kindergarten in Minami-Soma, about 20 kilometers away from the tsunami-crippled Fukushima Dai-ichi nuclear facility, in Fukushima Prefecture, northeastern Japan, Thursday, Aug. 18, 2011.(AP Photo/Hiro Komae)

"It is an extremely urgent task to decide how to manage houses and schools in cities, towns and villages," he said, adding that the government wants to consult with these local governments individually and respond to their needs to the best of its ability.

Hosono, who has been dealing with the Fukushima nuclear crisis triggered by the March 11 Great East Japan Earthquake and tsunami, said the new government will spend some time to discuss decommissioning the stricken plant.

"Setting an age limit on the life of a nuclear power plant is not necessary a scientific practice," he said, adding it is desirable to draw a line somewhere in the course of stress tests or by other means. He said the government should not prolong the operational span of nuclear power plants simply by weighing the financial conditions of respective electric companies.

Hosono said Japan hopes to keep its pledge to reduce greenhouse gas emissions by 25 percent from 1990 levels by 2020. But specific measures to achieve the target have to be reconsidered, he said, adding building nine new nuclear reactors as part of the Japanese anti-global warming campaign is no longer realistic.

Making Tohoku region final repository site for all nuclear waste simply not fair

When candidates running for the post of Democratic Party of Japan (DPJ) president were giving a joint press conference on Aug. 27 in Tokyo, then Prime Minister Naoto Kan was in Fukushima bowing apologetically to Fukushima Gov. Yuhei Sato.

"I have no choice but to ask that Fukushima Prefecture host an interim storage facility for nuclear waste and contaminated soil," Kan said.

"What are you talking about? This has come out of nowhere," Sato responded.

Toshio Seya, the head of the Fukushima Chamber of Commerce and adviser to Toho Bank, witnessed the melodramatic negotiations. Later, at a round-table meeting with reporters, Seya said, "Tokyo is the beneficiary of the nuclear power plant. Why not build (a radioactive waste storage facility) in Tokyo's Odaiba district?" (The comment was published in the Asahi Shimbun's Aug. 31 morning edition.)

Although shadowed by the drama of changing prime ministers, the above anecdote points to a serious problem that both anti-nuclear and pro-nuclear camps must face: where to store nuclear waste, at least for the time being.

Massive amounts of spent nuclear fuel are accumulating at nuclear power plants across Japan. On average, 64 percent of waste storage capacities at power plants are currently utilized. At old nuclear power stations, like those in Fukushima and Niigata prefectures, the figure is close to 90 percent, based on a survey conducted by Citizens' Nuclear Information Center (CNIC) for 2009.

This July 26, 2011 photo released by Tokyo Electric Power Co. and taken by the Quince, a radio-controlled robot developed by the Chiba Institute of Technology, shows the inside view around the stairs, bottom, at Unit 3 of the crippled Fukushima Dai-ichi nuclear power plant, in Okuma, Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Company)

Nuclear waste was supposed to have been reprocessed to be used again as fuel, if things had gone according to the government's 2005 Framework for Nuclear Energy Policy. But neither the prospects for recycling facilities nor fast-breeder nuclear reactors are good. And Japan has no final repositories. This is where the interim storage facilities come in, to buy time -- several decades -- until new technology is established to handle the problem on a more permanent basis.

Kan made the trip to Fukushima that day because he foresaw that leaving the task to the new prime minister would further delay the treatment and disposal of radiation-tainted soil and rubble. In appealing to the Fukushima governor for his cooperation in hosting a waste facility, Kan promised that it would only be used to store waste from within the prefecture, and also that it would not become a final repository for such waste.

There are two possible ways in which the new prime minister can go forward. The first option is to build up as many *faits accomplis* as possible, and eventually force the disaster-stricken Tohoku region to take on all nuclear waste. The alternative is to divide the responsibility of storing spent fuel among all prefectures.

A 23-page document titled "The Problem of the Nuclear Fuel Cycle's Back End" argues that the recycling of spent fuel is impossible and that the burden of storing nuclear waste must be shared by each prefecture. It also suggests giving prefectures the capacity to buy or sell storage amounts with each other. The document reads like a sequel to another document that was released years earlier.

That document is "The 19 trillion yen Invoice," a 25-page document critiquing the nuclear fuel cycle that caused a stir among government ministries in the spring of 2004. It had been written by a fringe group of Ministry of Economy, Trade and Industry (METI) bureaucrats who charged that the funds earmarked for the pointless bank-end stages of the fuel cycle totaled 19 trillion yen.

The construction of temporary storage sites for radiation-contaminated waste in the disaster-stricken region is unavoidable. The spent fuel in Fukushima cannot be transported elsewhere. However, taking advantage of such circumstances to make the Tohoku region a final repository of nuclear waste created around the country is simply unfair.

There was a time when the economy was booming and the government could afford to spend extra. Back then, compensation payments were routinely given out to resolve conflicts and contradictions. A bit of that practice still lingers, but the government no longer has the means to dole out massive amounts of cash anymore.

Looking back on the negotiations and discussions between the central and Fukushima Prefectural governments, one anecdote from 2009 stands out. A member of the Fukushima Prefectural Assembly asked how spent nuclear fuel would be treated, and when. A representative from the Agency for Natural Resources and Energy (ANRE) responded, "That is something that is up to each operator (power company)."

This is apparently the sentiment of METI's mainstream bureaucrats. Meanwhile, the new prime minister has not made any mention of the fuel cycle's back end. Will he be able to rectify the mainstream's irresponsibility, rigidity and decadence, and thereby alter the direction in which we are headed? Or will he retreat into the security of the status quo out of fear of turmoil? (By Takao Yamada, Expert Senior Writer)

Fukushima No. 3 reactor bottom's temperature falls below 100 C

This March 24, 2011 aerial photo, taken by a small unmanned drone and released by Air Photo Service, shows the damaged Unit 3 of the crippled Fukushima Dai-ichi nuclear power plant in Okumamachi, Fukushima Prefecture, northeastern Japan. (AP Photo/ Air Photo Service)

TOKYO (Kyodo) -- Tokyo Electric Power Co. said Monday that the temperature of the crippled No. 3 nuclear reactor at the Fukushima Daiichi atomic power plant has fallen below 100 C, signaling progress toward the plant's cold shutdown.

It is the first time that the temperature measured at the bottom of the No. 3 reactor pressure vessel dropped below 100 C since the nuclear crisis began at the complex in March due to a devastating earthquake and tsunami. The No. 1 reactor is already below 90 C.

The plant operator known as TEPCO said using an additional cooling method of showering water to the reactor core is likely to have helped lower the temperature of the No. 3 reactor pressure vessel.

TEPCO is considering applying the same method to the No. 2 reactor.

The utility has said the Nos. 1 to 3 reactors' cores are assumed to have suffered meltdowns and the melted fuel is believed to be solidified at the bottom of the pressure vessels.

Cooling the pressure vessels of the plant's damaged Nos. 1 to 3 reactors is part of the key conditions to realize the plant's cold shutdown, which the government and TEPCO hopes to achieve by January at the latest.

The cold shutdown is also defined by the government and TEPCO as a state in which the release of radioactive materials from reactors is under control and radiation exposure dose is significantly held down.

(Mainichi Japan) September 6, 2011

TEPCO to build wall off Fukushima Daiichi plant

The operator of the damaged Fukushima Daiichi nuclear power plant plans to build an iron wall on the ocean side of the plant to prevent radioactive water from leaking into the sea.

Tokyo Electric Power Company says more than 110,000 tons of highly radioactive water remains in the basements of reactor buildings at the plant. There is growing concern that the water may eventually pass via underground water into the ocean.

The utility will use thousands of iron pipes to create an 800-meter-long wall surrounding the water intakes of 4 reactor facilities.

Each pipe, 22-meters long and one meter wide, will be installed deep below the sea bed to stop the flow of groundwater.

The firm says it will also prepare for a rise in underground water levels around the plant after the wall is built. It says it will closely monitor the level of groundwater and consider pumping it away to prevent overflow.

Construction will begin as early as the end of this year and be completed in about 2 years.

Prevention of sea-water contamination is one of pillars in the company's roadmap to contain the nuclear accident.

No. of Japan's nuclear plants to be zero in future: Hachiro

TOKYO (Kyodo) -- Industry minister Yoshio Hachiro said Tuesday that the number of Japan's nuclear power plants would be "zero" in the future, based on Prime Minister Yoshihiko Noda's policy of not building new nuclear power plants and decommissioning aged ones.

"Considering the premier's remarks at press conferences, it would be zero," Hachiro told reporters in answer to the question whether the number of nuclear plants would reduce to none in the future.

Hachiro added that it would be "difficult" to proceed with plans to build new nuclear plants whose construction has yet to begin, such as Chugoku Electric Power Co.'s Kaminoseki plant in Yamaguchi Prefecture. "Public opinion is generally united in reducing (nuclear plants), instead of increasing them," he said.

As for nuclear power plants whose construction has begun, such as Chugoku Electric's Shimane plant's No. 3 reactor in Shimane Prefecture and Electric Power Development Co.'s Oma nuclear power plant in Aomori Prefecture, Hachiro said he intends to make a decision based on discussions at the ministry's advisory committee on energy and natural resources.

Japan currently plans to set up 12 reactors nationwide, excluding the Fukushima Daiichi nuclear power plant's No. 7 and 8 reactors, whose construction plan was canceled by the plant operator Tokyo Electric Power Co. in the wake of the nuclear crisis at the complex. But construction has not progressed much for most of the projects.

As for the resumption of reactors idled for regular checkups, Hachiro said that Noda has approved a plan to seek safety assessments from the International Atomic Energy Agency as part of the so-called nuclear "stress tests" introduced by the Japanese government given the Fukushima crisis.

Hachiro has said he aims to resume operations of the halted reactors nationwide soon once their safety is thoroughly checked and local municipalities hosting the plants approve their resumption.

Meanwhile, Hachiro admitted that Japan has received an offer from French nuclear power company Areva SA to take charge of spent nuclear fuel at the troubled Fukushima Daiichi plant, but he did not reveal Japan's response to the offer.

(Mainichi Japan) September 6, 2011

13 idled reactors enter 1st stage of safety evaluation process

TOKYO (Kyodo) -- A total of 13 of the around 30 reactors in Japan idled for regular checks have entered the first stage of the safety evaluation process, a step set as a precondition for restarting them following the Fukushima nuclear crisis, Kyodo News learned Tuesday.

Kansai Electric Power Co. and Shikoku Electric Power Co., which serves some areas in western Japan and Shikoku Island, plan to submit evaluation reports on their six idled reactors to the government's Nuclear and Industrial Safety Agency by the end of this month.

The other four utility companies hoping to restart the remaining seven reactors are also accelerating efforts to do so, aiming to resume operation of their reactors as early as year-end.

The safety evaluation process was set by the government in July as a precondition for the restarting of reactors following the nuclear crisis at the Fukushima Daiichi power plant triggered by the March 11 earthquake and tsunami.

Japan's new Prime Minister Yoshihiko Noda has shown a positive stance toward restarting idled reactors to ensure a stable supply of electricity.

It remains uncertain whether local governments will give their approval for the resumption of reactors, which is also required to restart them.

The 13 reactors are the Nos. 1 and 2 reactors at Hokkaido Electric Power Co.'s Tomari plant, the No. 1 unit at Tohoku Electric Power Co.'s Higashidori plant, the No. 2 unit at Hokuriku Electric Power Co.'s Shiga plant, Kansai Electric's Nos. 1 and 3 units at its Mihama plant and Nos. 1 and 3 units at its Oi plant as well as the No. 1 unit at its Takahama plant, the No. 3 unit at Shikoku Electric's Ikata plant, and Kyushu Electric Power Co.'s Nos. 2 and 3 units at its Genkai plant and the No. 1 unit at its Sendai plant.

The utility companies have been checking the safety of the reactors, including their ability to withstand earthquakes and tsunami, since late July.

After the government's nuclear safety agency and the Nuclear Safety Commission of Japan screen their reports, Noda, industry minister Yoshio Hachiro, nuclear disaster minister Goshi Hosono and chief Cabinet secretary Osamu Fujimura will decide on whether to allow the reactors to be restarted.

If approved by both the central and local governments, Japan will see its first reactor restart since the Fukushima nuclear crisis, excluding the No. 3 reactor at the Tomari plant, which shifted from an "adjustment operation" in the final phase of checks to commercial operation in mid-August.

Before the Fukushima nuclear crisis, more than 30 reactors were operating in Japan. But given the effects of the March disaster and the need to regularly suspend reactors for checks, only 11 of Japan's 54 commercial reactors are currently in operation.

If the resumption of their operation is not allowed, all of Japan's 54 reactors will be out of operation by May.

Rezo-nukes

September 7, 2011

ACRO has again analyzed the urine of Japanese children and the results are unambiguous: all children in Fukushima were or are contaminated, while we have not found any contamination in the urine of children in Tokyo and surroundings.

Fukushima children who were evacuated by their parents saw their contamination of the urine drop. More than four months after the massive discharges of radioactivity into the environment, others are still contaminated, although their parents do their best to reduce this contamination. It is likely that this is due to food.

The results are detailed with comments on our website: <http://acro.eu.org>

While the tests performed by the Japanese authorities gives about one child from Fukushima out two that is contaminated, we get 100%. This reflects the fact that the official measurements are not accurate enough and did not detect all contaminations.

It is important to conduct an accurate, systematic and regular monitoring of internal contamination of children from Fukushima. Families must have access to the measurement of radioactivity to help them reduce this contamination.

Fukushima : le Japon durablement contaminé

ACRO

<http://acro.eu.org>

Article écrit pour la revue du [Réseau Sortir du Nucléaire](#)

Dans une vidéo mise en ligne le 17 août sur son site (à [télécharger ici](#)), le directeur de la centrale de Fukushima Dai-ichi prie la population de l'excuser pour les « *désagréments et l'anxiété causés par l'accident* ». TEPCO n'aurait ainsi causé que des désagréments et de l'anxiété ? Et d'ajouter sans vergogne qu'ils font tout pour que les personnes déplacées puissent revenir au plus vite chez elles.

Des rejets massifs de radioéléments

Même arrêtée, une centrale nucléaire est menaçante : la forte chaleur dégagée par la radioactivité du combustible doit être évacuée dans le cœur du réacteur puis pendant des années en piscine. Sans électricité et eau, pas de refroidissement et la pression monte. Il faut donc dépressuriser les réacteurs pour éviter qu'ils n'explosent. C'est ce qui s'est passé dans les réacteurs 1 à 3 de la centrale de Fukushima frappée par un puissant séisme et un tsunami, entraînant des rejets radioactifs massifs. Comme le combustible a fondu, il n'est plus protégé par sa gaine, et les éléments très radioactifs sont en contact direct avec l'eau et l'air. Les explosions hydrogène qui ont eu lieu dans trois des six réacteurs de la centrale et au niveau de la piscine d'un quatrième ont aussi provoqué de forts dégagements de gaz radioactifs.

Tout un cocktail de radioéléments a été rejeté. La quantité estimée a posteriori a changé au cours du temps et dépend de l'organisme qui a fait les calculs. Une chose est sûre, c'est que l'on n'est pas loin des quantités rejetées par Tchernobyl. Les niveaux de contamination relevés jusqu'à des dizaines de kilomètres de la centrale sont aussi similaires à ceux relevés dans les territoires contaminés de Biélorussie. Avec cependant quelques petites différences : contrairement à Tchernobyl, où un incendie a entraîné une forte contamination de la Scandinavie par exemple, les vents dominants ont emporté la majorité de la radioactivité émise par la centrale de Fukushima vers l'Océan Pacifique. Les relevés effectués autour de la centrale ont aussi montré que très peu de plutonium est sorti, alors qu'en Biélorussie, la contamination en plutonium, très toxique, doit être prise en compte dans la délimitation des zones à évacuer. La contamination en strontium est aussi relativement plus faible qu'autour de Tchernobyl.

L'évacuation pour protéger les populations

Les habitants ont été rapidement évacués, parfois dans des conditions chaotiques, dans un rayon de 20 km autour de la centrale et confinés jusqu'à 30 km pour éviter l'exposition au panache radioactif. Le confinement a duré des semaines avant que les habitants soient invités à partir. Comme la centrale est encore menaçante et que l'on ne peut pas exclure de nouveaux rejets une distance de sécurité de 30 km est maintenue. En effet, la centrale est fragilisée et les séismes continuent. À cela s'ajoute la contamination de vastes territoires qui fait qu'une grande partie de ces gens ne pourront pas rentrer chez eux. Ce sont près de 80 000 personnes jusqu'à une quarantaine de kilomètres de la centrale qui ont finalement été évacuées. Et ce n'est sûrement pas suffisant.

Évacuer est une décision terrible, car on perd tout, maison, emploi... C'est aussi le démantèlement des communautés et du lien social très fort au Japon. Les agriculteurs sont les plus pénalisés car ils n'ont presque aucun espoir de retrouver des terres. Nombreux ont refusé de partir et sont restés avec leurs bêtes. Quand les autorités ont bouclé la zone des 20 km autour de la centrale, fin avril, 45 irréductibles ont refusé de partir.

Pourtant, les conséquences de la radioactivité sont pires que l'évacuation et personne n'a réclamé une zone d'évacuation plus étroite. En revanche, les appels à l'élargissement de la zone sont nombreux. Les autorités japonaises ont fixé à 20 millisieverts par an la limite de risque acceptable pour la population, comme pour les travailleurs du nucléaire. C'est 20 fois plus qu'en temps normal et c'est inacceptable (un

argumentaire d'ONG japonaises de 16 pages sur le sujet peut être [téléchargé ici](#)). Car, contrairement aux travailleurs du nucléaire qui sont sélectionnés et suivis médicalement, il y a des personnes fragiles et vulnérables parmi la population qui doivent être mieux protégées. C'est le cas des enfants particulièrement sensibles aux radiations. Où mettre la limite ? Jusqu'où évacuer ? Ce n'est pas une décision facile. Interrogée par l'ACRO, l'[IRSN](#) a déclaré qu'elle recommanderait de mettre la limite à 10 millisieverts par an en cas de situation similaire en France. Et d'ajouter que cela impliquerait d'évacuer 70 000 personnes supplémentaires au Japon. De fait, les familles qui peuvent se le permettre sont parties, ou se sont séparées, la mère et les enfants, ou les enfants seuls envoyés plus loin. Sans aide gouvernementale, d'autres n'ont pas le choix et doivent rester.

La délimitation des zones d'évacuation est seulement définie à partir de l'irradiation externe due aux retombées sur le sol. Mais, les personnes ne partent pas de zéro puisqu'elles ont été exposées aux retombées radioactives : le logiciel SPEEDI développé après Tchernobyl pour calculer l'impact des panaches radioactifs en cas d'accident n'a servi à rien, ou presque. Les prévisions n'étaient pas publiées et pas utilisées par les autorités. Des personnes ont été évacuées dans un abri situé sous les vents dominants où les enfants ont joué dehors. Et la contamination interne risque de continuer via l'alimentation, l'inhalation de poussières...

De la radioactivité détectée à travers tout le pays

L'ACRO a détecté du césium 134 et 137 dans toutes les urines des enfants de la ville de Fukushima qu'elle a contrôlés. Les prélèvements ont été faits par des associations locales avec lesquelles nous sommes en contact. Les niveaux étaient faibles, mais montrent que la contamination interne existe et doit être prise en compte. Les données officielles ([traduites en anglais ici](#)) font état de cas avec de plus fortes contaminations. En revanche, la limite de détection des autorités est trop élevée pour pouvoir se faire une idée du nombre de personnes contaminées. Il est important que le suivi officiel soit plus rigoureux.

Des retombées radioactives ont été retrouvées très loin en quantité significative. Du thé radioactif au-delà des normes a été détecté jusqu'à Shizuoka, à environ 300 km de la centrale. De la paille de riz, qui sert à alimenter le bétail, a aussi été retrouvée jusqu'à Iwaté, plus au Nord. L'eau a concentré cette pollution dans les cours d'eau et les stations d'épuration dont les boues sont radioactives. Le pays ne sait pas comment faire face à tous ces déchets radioactifs nouveaux.

Certaines de ces boues ont été incinérées, entraînant une contamination locale importante. L'ACRO a mesuré une contamination en césium dans un sol de l'arrondissement de Kôtô-ku de Tôkyô qui nécessite une surveillance radiologique. De la paille de riz contaminée a été vendue jusqu'à Mié, à 600 km de la centrale, rendant la viande de bœuf radioactive. Le fumier a servi à faire du compost à Shimané à l'autre bout du pays.

La chaîne alimentaire est contaminée

La chaîne alimentaire est donc touchée et la crise provoquée par la découverte de viande de bœuf radioactive au-delà des normes sur les étals a montré que les contrôles officiels n'étaient pas suffisants. Le

pays importe près de 60% de sa nourriture, mais est autosuffisant en riz. L'agriculture dans les zones évacuées est suspendue. Au-delà, elle est fortement perturbée, de nombreux aliments ne pouvant pas être mis sur le marché (pour le césium radioactif (césium 134 + césium 137), les autorités japonaises ont fixé à 500 Bq/kg la limite au-delà de laquelle un aliment ne peut pas être vendu). Heureusement, la plupart des aliments vendus en supermarché sont peu ou pas contaminés. Les aliments qui ne passent pas par les circuits commerciaux échappent aux contrôles.

Les végétaux peuvent être contaminés de deux façons. D'abord par les feuilles directement exposées aux retombées. Le transfert est élevé, mais cela ne dure que le temps d'une récolte. Si l'accident de Tchernobyl avait eu lieu en juin, une grande partie de la production de blé en France n'aurait pas pu être consommée. L'autre mode de contamination est via les racines. Le taux de transfert est généralement faible, mais dans les zones très contaminées, cela rend la production d'aliments impossible pendant des décennies à cause du césium 137 qui a une demi-vie de 30 ans. Le thé de Shizuoka devrait pouvoir être consommé sans problème dans l'avenir.

La culture du riz est plus problématique : une étude de l'université de Tokyo, en collaboration avec la province de Fukushima, a montré que le césium s'enfonçait plus vite dans le sol que ce qui était généralement admis, rendant une décontamination des terrains quasiment impossible. De plus, les fortes pluies de juin et les typhons ont lessivé les sols et concentré la radioactivité dans les rivières. Celle-ci risque ensuite de diffuser lentement dans les rizières où elle va rester piégée. Une surveillance accrue s'impose pendant de longues années.

Le milieu marin est aussi très touché

À toute cette contamination terrestre, s'ajoute une forte pollution radioactive en mer. Outre les rejets aériens qui ont aussi contaminé l'océan sur une grande surface, TEPCO a dû faire face à une forte fuite d'eau très radioactive qui a contaminé durablement la côte. Au même moment, la compagnie a rejeté volontairement de l'eau moyennement radioactive, ce qui a provoqué une confusion et un tollé.

Les sous-sols inondés des réacteurs débordaient dans la mer et il fallait pouvoir pomper cette eau fortement contaminée. TEPCO a donc vidé des cuves pour faire de la place. Pour l'iode, ces rejets volontaires étaient dix fois plus faibles qu'une année de rejets de l'usine Areva de La Hague. En revanche, TEPCO a annoncé que la fuite d'eau du réacteur n°2 a entraîné un rejet estimé à 520 m³ d'eau très radioactive, soit 4 700 térabecquerels (1 térabecquerel représente un million de millions de becquerels) ou 20 000 fois l'autorisation de rejet annuel. Ce seul rejet mériterait d'être classé au niveau 5 ou 6 de l'échelle internationale INES.

La centrale de Fukushima étant proche du point de rencontre de deux courants marins, cette pollution devait être rapidement emportée au large et les autorités se voulaient rassurantes. Mais il n'en est rien. Des mois plus tard, les analyses faites par l'ACRO pour Greenpeace sur des poissons et algues prélevés à des dizaines de kilomètres de la centrale montrent une contamination persistante. Certains de ces échantillons dépassent la limite fixée en urgence par les autorités japonaises pour les produits de la mer. Les fonds marins sont aussi contaminés.

Si les algues et les poissons sont contaminés, l'eau de mer doit l'être aussi. Mais les analyses effectuées par les autorités japonaises ne sont pas assez précises : en dessous de la limite de détection de quelques becquerels par litre, il est annoncé "non détectable". Or il est nécessaire d'avoir des limites plus basses, car la vie marine a tendance à concentrer cette pollution. La pollution en iode peut être 1 000 fois plus forte dans une algue que dans l'eau. La [société d'océanographie du Japon](#) a aussi réclamé des mesures plus précises sur l'eau de mer. Les données sur le strontium sont trop rares.

Un impératif : multiplier les mesures indépendantes

Les rejets continuent. Actuellement, suite à la fusion des trois cœurs de réacteurs qui ont percé les cuves, TEPCO refroidit le magma en injectant de l'eau par le haut et qui ressort via les fuites dans les sous-sols après avoir été fortement contaminée. Il y en a 120 000 m³ dans des structures qui n'ont pas été prévues pour stocker l'eau. TEPCO tente, tant bien que mal, de décontaminer cette eau avant de la réinjecter dans les réacteurs et ose parler de « circuit fermé ». Une partie s'évapore car les réacteurs sont encore très chauds, une autre s'infiltre partout.

Fin avril, TEPCO estimait à 1 térabecquerel par heure (1 million de millions de becquerels par heure) les rejets de la centrale. Ils seraient en baisse. Les rejets étaient estimés à 6,4 fois plus début avril. Fin juillet, TEPCO estime à environ 1 milliard de becquerels par heure les rejets aériens actuels des 3 réacteurs accidentés. Ce chiffre est estimé à partir des mesures faites à l'extérieur à partir de balises. TEPCO est en train de construire comme une tente par-dessus le réacteur n°1 pour contenir les effluents gazeux. Les autres suivront. Elle prévoit aussi d'installer une barrière souterraine pour retenir les fuites vers la mer.

Face à une telle situation, malheureusement durable, l'accès à la mesure de la radioactivité est primordial. On ne compte plus les initiatives en ce sens. Des universitaires sont en train de finaliser une [cartographie dans un rayon de 80 km](#) autour de la centrale. Un [groupe Facebook](#) a fait analyser de nombreux échantillons de sol de Tokyo... On trouve sur Internet de nombreux relevés de débit de dose ambiant fait par les autorités ou des amateurs. L'ACRO est en contact avec plusieurs projets de vrais laboratoires pouvant distinguer la pollution radioactive de la radioactivité naturelle. Dans certains cas, nous avons juste fourni du conseil technique. Dans d'autres nous avons installé le laboratoire, testé et qualifié les détecteurs, formé les utilisateurs. Afin de favoriser l'entraide technique et la coopération nous avons aussi initié un réseau. Et pour que ces projets soient pérennes, nous avons lancé une souscription pour ouvrir un laboratoire aussi sophistiqué que le nôtre sur place qui prendrait le relais du soutien technique que nous fournissons actuellement. Cela en collaboration étroite avec les associations avec lesquelles nous sommes en contact depuis de très nombreuses années.

Un projet aussi ambitieux prend du temps à se mettre en place. En attendant, l'association a analysé gracieusement de nombreux échantillons dans son laboratoire en France. Pour nous permettre de continuer, l'ACRO a besoin de votre soutien financier.

TEPCO submits heavily redacted copy of Fukushima nuke accident manual

Copies of a heavily redacted nuclear accident manual submitted to a Diet committee by Tokyo Electric Power Co. are pictured on Sept. 7. (Mainichi)

A Diet science committee says it has received a heavily censored copy of a nuclear accident operating manual for the crippled Fukushima No. 1 nuclear plant from Tokyo Electric Power Co. (TEPCO).

The House of Representatives Special Committee on Promotion of Science and Technology and Innovation had requested TEPCO submit two operating manuals -- one each for accidents and severe accidents -- through the Economy, Trade and Industry Ministry (METI), but said Sept. 7 that it had received only the former document, which had itself been significantly redacted. The panel, chaired by Hiroshi Kawauchi of the ruling Democratic Party of Japan, said it needed the manuals and other pertinent documents on Aug. 26 to help probe the cause of the ongoing nuclear disaster, and has requested TEPCO to resubmit the manuals by Sept. 9.

The 6-page manual for nuclear accidents TEPCO did submit was divided into four sections, including "main item" and "shift supervisor (deputy shift supervisor)." The document was, however, nearly unreadable because most of it had been blacked out. Even those sections left visible had holes, such as one sentence that read: "When reactor pressure rises, stabilizes the pressure at (redacted) Mpa by using an emergency condenser and other techniques, and report."

According to the METI's Nuclear and Industrial Safety Agency (NISA), TEPCO submitted them to NISA on Sept. 2 after seeking a guarantee of nondisclosure the day before. NISA rejected the utility's request, but then simply delivered the TEPCO documents to the committee.

Sources said TEPCO defended the censored documents, saying they contain intellectual property and may cause problems concerning the protection of nuclear materials.

Committee Chairman Kawauchi said the blacked out documents "are extremely regrettable. If TEPCO refuses to resubmit the manuals in question, we will consider summoning TEPCO executives as unsworn witnesses."

<http://news.yahoo.com/paris-court-drops-case-chernobyl-fallout-075633122.html>

Paris court drops case on Chernobyl fallout

PARIS (AP) — A Paris court has dropped a long-running investigation into whether the 1986 Chernobyl nuclear accident caused health problems in France.

The lawyer for the complainants, Bernard Fau, said the Paris appeals court ruled Wednesday to close the case.

The then-chief of France's radiation safety agency, Pierre Pellerin, had faced preliminary charges in the case for "aggravated deception."

Researchers and cancer victims accuse the government of intentionally downplaying the risks of the radioactive cloud that the accident in then-Soviet Ukraine spewed over much of Europe, in part to protect France's powerful nuclear industry.

But the prosecutor said earlier this year that the probe had turned up no hard proof that Pellerin misled the public on purpose.

Rising radioactive cesium levels detected in Fukushima child's urine

Increased radioactive cesium levels were detected in a urine sample taken from a child who continued to live in Fukushima Prefecture after the meltdowns at the Fukushima No. 1 nuclear plant, a citizens group has announced.

On Sept. 7, Fukushima Rokyū Genpatsu o Kangaeru Kai (An association for a study of the aging nuclear power plants in Fukushima) released the results of urine tests on 10 people aged between 6 and 16 who lived in the city of Fukushima at the beginning of the nuclear disaster in March. At the time of the first round of testing on May 20-22, all 10 children were living in Fukushima Prefecture, while at the time of the second round conducted July 22 through 26, nine had evacuated to other parts of Japan.

Results showed cesium levels in the nine children who had left the prefecture had dropped by roughly 20 to 70 percent in the some two months between the tests. Radioactive cesium 137 levels in the one

child who had remained in the city of Fukushima, however, had spiked by 11.5 percent as of the July tests.

"We assume the child was exposed to additional radiation through food and drink," a representative of the citizens group said.

The group, comprised of citizens and professors, has been conducting follow-up testing on Fukushima children's urine to study their internal exposure. The group commissioned ACRO -- a French civilian organization studying radioactive materials -- in May to analyze urine samples collected from the 10 children.

(Mainichi Japan) September 8, 2011

Above-the-limit cesium found in Iwate beef, 1st since shipments OK'd

MORIOKA (Kyodo) -- Radioactive cesium exceeding the legal limit has been detected in beef cattle in Iwate Prefecture for the first time since the ban on shipments in the region was lifted last month, local officials said Thursday.

The amount of cesium found topped the government-set allowable limit of 500 becquerels per kilogram in two of eight beef cattle following shipment, the officials said.

Cesium was first detected in the eight cattle in a simple test Tuesday, the officials said, adding that two of the eight were destroyed after further tests confirmed they had excessive levels of the element.

The cattle shipment ban was imposed following the discovery of beef contaminated with radioactive cesium from cattle raised in northeastern Japan, in the wake of the nuclear crisis at the Fukushima Daiichi power plant triggered by the March 11 earthquake and tsunami.

(Mainichi Japan) September 8, 2011

Sea radiation leaks reach 15,000 terabecquerels off Fukushima plant

TOKYO (Kyodo) -- Researchers estimate that amount of radioactive substances that leaked into the sea from the crippled Fukushima Daiichi nuclear power plant between March 21 and April 30 totaled 15,000 terabecquerels, an entity which led the research work said Thursday.

The estimate compares with 4,700 terabecquerels of radioactive iodine and cesium that the plant operator, Tokyo Electric Power Co., estimated had leaked into the sea between April 1 and 6 from a water inlet at the No. 2 reactor at the four-reactor plant following the March 11 earthquake and tsunami.

The big gap indicates radioactive substances could have leaked through other channels as well as the No. 2 reactor inlet, said Takuya Kobayashi, a senior researcher at the Japan Atomic Energy Agency which led the estimate work.

The researchers' estimate will be reported at a meeting of the Atomic Energy Society of Japan starting Sept. 19 in Kitakyushu, Fukuoka Prefecture.

Nuclear experts: Radiation-contaminated areas in Fukushima disaster only one-tenth of Chernobyl's

A government map displaying radiation levels in the area around the Fukushima No. 1 Nuclear Power Plant. An English version can be found on the page linked below.

The Atomic Energy Society of Japan (AESJ) suggests in a recent survey that the total area of radioactive contamination following the nuclear meltdowns in Fukushima in March equaled no more than one-tenth of that in the Chernobyl accident in 1986.

The survey shows that approximately 800 square kilometers is contaminated with levels of radioactive cesium exceeding 600,000 becquerels per square meter, whereas in Chernobyl the total area exceeding 555,000 becquerels per square meter topped 10,000 square kilometers. Based on these results, the

Society's nuclear experts estimated that radiation contamination area in the Fukushima disaster equals no more than one-tenth that in the Chernobyl disaster.

Meanwhile, a soil radiation map of over 2,200 locations within a 100-kilometer radius of the Fukushima No.1 Nuclear Power Plant, released by the Ministry of Education, Culture, Sports, Science and Technology (MEXT) on Aug. 29, shows 34 locations with levels of cesium exceeding 1.48 million becquerels per square meter, the level used as the basis for issuing compulsory evacuation orders in areas near the Chernobyl plant.

A member of a government decontamination team checks radiation levels at a playground in Date, Fukushima Prefecture, on Aug. 24. (Mainichi)

According to experts at the Ibaraki Prefecture-based National Institute for Agro-Environmental Sciences -- in charge of monitoring rice fields in 15 locations across the country -- previously the most severe soil radiation in the history of Japan was measured in 1967 at 138 becquerels per kilogram, following a series of nuclear experiments in the 1960s.

A map showing levels of radioactive cesium (cesium-137 and cesium-134) in all surveyed zones is regularly updated on MEXT's website, while online map search sites such as www.geocoding.jp allow users to pinpoint particular monitoring locations.

Gov't must learn lessons from nuclear crisis response to avoid repeating mistakes

A radiation expert says what has infuriated him most since crisis broke out at the Fukushima No. 1 Nuclear Power Plant is that the government initially withheld data from the System for Prediction of Environmental Emergency Dose Information (SPEEDI), which predicted how radioactive substances would spread. His anger is understandable.

Clouds of radioactive substances drifted northwest as well as toward the Kanto area around Tokyo between March 15 and 16, and between March 20 and 22. There are many people who fled to areas that the clouds were drifting towards, and those who allowed their children to play outdoors without knowing how radioactive substances were spreading. It is difficult to imagine how people saying, "If I had only known about the projections ..." are feeling now.

As if to add insult to injury, it has turned out that projections made on March 11 of nuclear reactor core meltdowns were ignored by the Prime Minister's Office. It is surprising that the government has disclosed this fact at this stage, but its claim that it "never thought of utilizing the data because it is not based on confirmed facts" is also astounding. Exactly because facts cannot be immediately confirmed, the government should have protected residents of affected areas by making predictions. SPEEDI, as well as a system to predict meltdowns, exists for that very purpose.

The government is now paying the price for ignoring the projections of the widespread diffusion of radioactive substances. Numerous beef cows were contaminated with radiation through tainted feed, and so-called hot spots -- sites where radiation levels are far higher than the surrounding area -- have been discovered one after another. The government's acknowledgement, six months after the nuclear crisis began, that residents of highly contaminated areas cannot return home for decades also appears to be an "after-effect" of ignoring the diffusion predictions.

University of Tokyo professor Tatsuhiko Kodama has urged that an expert committee comprised of "fresh" members be set up to protect children and expecting mothers from radiation, and promote the decontamination of affected areas in an appropriate manner. Kodama places emphasis on "fresh" members because he fears that experts who have been involved in the past mistakes will only make excuses. His opinion is convincing, considering the government's response to the nuclear crisis.

Unfortunately, all the Diet members were directly or indirectly involved in the mistakes. Therefore, all politicians should confront the mistakes made in the days and weeks after the meltdowns. The new administration of Prime Minister Yoshihiko Noda must pay close attention to the crisis to see if any mistake is being made, and eliminate the causes of any potential mistake. ("Yoroku," a front-page column in the Mainichi Shimbun)

Fukushima Radioactive Release Into Pacific Ocean Estimated Triple

September 8, 2011

<http://visionsgreen.com/blog/2011/09/08/fukushima-radioactive-release-into-pacific-ocean-estimated-triple/>

A group of Japanese researchers say that a total of 15,000 terabecquerels of radioactive substances is estimated to have been released from the crippled Fukushima Daiichi nuclear power plant into the sea.

Researchers at the Japan Atomic Energy Agency, Kyoto University and other institutes made the calculation of radioactivity released from late March through April.

The combined amount of iodine-131 and cesium-137 is more than triple the figure of 4,720 terabecquerels earlier estimated by Tokyo Electric Power Company, the plant operator. The utility only calculated the radioactivity from substances released from the plant into the sea in April and May.

The researchers say the estimated amount of radioactivity includes a large amount that was first released into the air but entered the sea after coming down in the rain.

They say they need to determine the total amount of radioactivity released from the crippled Fukushima Daiichi plant in order to accurately assess the impact of the disaster on the sea.

Radiation expert says outcome of nuke crisis hard to predict, warns of further dangers

As a radiation metrology and nuclear safety expert at Kyoto University's Research Reactor Institute, Hiroaki Koide has been critical of how the government and Tokyo Electric Power Co. (TEPCO) have handled the nuclear disaster at the Fukushima No. 1 nuclear plant. Below, he shares what he thinks may happen in the coming weeks, months and years.

The nuclear disaster is ongoing. Immediately after the crisis first began to unfold, I thought that we'd see a definitive outcome within a week. However, with radioactive materials yet to be contained, we've remained in the unsettling state of not knowing how things are going to turn out.

Without accurate information about what's happening inside the reactors, there's a need to consider various scenarios. At present, I believe that there is a possibility that massive amounts of radioactive materials will be released into the environment again.

At the No. 1 reactor, there's a chance that melted fuel has burned through the bottom of the pressure vessel, the containment vessel and the floor of the reactor building, and has sunk into the ground. From there, radioactive materials may be seeping into the ocean and groundwater.

The use of water to cool down the reactors immediately after the crisis first began resulted in 110,000 cubic meters of radiation-tainted water. Some of that water is probably leaking through the cracks in the concrete reactor buildings produced by the March 11 quake. Contaminated water was found flowing through cracks near an intake canal, but I think that's just the tip of the iceberg. I believe that contaminated water is still leaking underground, where we can't see it. Because of this, I believe immediate action must be taken to build underground water barriers that would close off the nuclear power plant to the outside world and prevent radioactive materials from spreading. The important thing is to stop any further diffusion of radioactive materials.

The government and plant operator TEPCO are trumpeting the operation of the circulation cooling system, as if it marks a successful resolution to the disaster. However, radiation continues to leak from the reactors. The longer the circulation cooling system keeps running, the more radioactive waste it will accumulate. It isn't really leading us in the direction we need to go.

It's doubtful that there's even a need to keep pouring water into the No.1 reactor, where nuclear fuel is suspected to have burned through the pressure vessel. Meanwhile, it is necessary to keep cooling the No. 2 and 3 reactors, which are believed to still contain some fuel, but the cooling system itself is unstable. If the fuel were to become overheated again and melt, coming into contact with water and trigger a steam explosion, more radioactive materials will be released.

TEPCO says it is aiming to bring the No. 1, 2 and 3 reactors to cold shutdown by January 2012. Cold shutdown, however, entails bringing the temperature of sound nuclear fuel in pressure vessels below 100 degrees Celsius. It would be one thing to aim for this in April, when the government had yet to confirm that a meltdown had indeed taken place. But what is the point of "aiming for cold shutdown" now, when we know that fuel is no longer sound?

In the days ahead, the storage of enormous quantities of radiation-contaminated waste, including tainted mud resulting from the decontamination process, will become a major problem. Because the responsibility for spreading nuclear materials into the environment lies with TEPCO, it makes sense to bring all the radioactive waste to TEPCO headquarters in Tokyo.

Since that's not possible, the waste should be taken to the grounds of the nuclear power plant. If the plant is not large enough to accommodate all the waste, then a location close to the plant will also have to be designated as a nuclear graveyard. However, no one should take advantage of the chaos and force Fukushima to host interim radioactive waste repositories for spent fuel from other nuclear power plants.

Recovering the melted nuclear fuel is another huge challenge. I can't even imagine how that could be done. When the Three Mile Island accident took place in 1972, the melted nuclear fuel had stayed within the pressure vessel, making defueling possible. With Fukushima, however, there is a possibility that nuclear fuel has fallen into the ground, in which case it will take 10 or 20 years to recover it. We are now head to head with a situation that mankind has never faced before.

Over 100,000 Fukushima Prefecture residents can't return to hometowns

In this photo taken July 26, 2011, playground equipment stands in front of Karino Elementary School which was used as an evacuation shelter in the town of Namie, Fukushima Prefecture, northeastern Japan. Japan's system to forecast radiation threats was working from the moment the nuclear crisis began. As officials planned a venting operation certain to release radioactivity into the air, the system predicted the elementary school would be directly in the path of the plume emerging from the tsunami-hit Fukushima Dai-Ichi nuclear plant. But the prediction helped no one. Nobody acted on it. The school, just over 10 kilometers from the plant, was not immediately cleared out. Quite the opposite. It was turned into a temporary evacuation center. (AP Photo)

More than 100,000 Fukushima Prefecture residents are still not able to return to their municipalities due to the ongoing nuclear disaster at the Fukushima No. 1 Nuclear Power Plant, a Mainichi survey has found.

As of the end of August, a total of 101,931 residents from 12 cities, towns and villages in Fukushima Prefecture that are subject to a range of evacuation measures were forced to live outside their municipalities. Some locations near the crippled nuclear power plant are estimated to be contaminated with accumulated radiation doses of more than 500 millisieverts a year, diminishing residents' hopes of a homecoming anytime soon.

Even areas away from the plant are still suffering from a sharp decline in the number of tourists and sluggish financial conditions, underscoring the impact of the nuclear crisis that is plaguing Fukushima Prefecture six months on from the March 11 earthquake and tsunami that started it.

The Mainichi Shimbun asked 12 municipalities in the no-go zones, planned evacuation zones, and emergency evacuation preparation zone how many of their residents had been evacuated to other municipalities as of Aug. 31. The city of Minamisoma had the most evacuees, at 25,184, followed by the town of Namie at 20,115.

The Ministry of Education, Culture, Sports, Science and Technology estimates that annual radiation doses will top 20 millisieverts at 35 locations within the no-go zones. Decontamination is also a major issue faced by affected municipalities in the emergency evacuation preparation zones. As of Sept. 8, a total of 16 elementary and junior high schools in such zones remained closed.

The estimated population of Fukushima Prefecture has also dipped below 2 million for the first time in 33 years, standing at 1,997,400 as of July 1. While the prefecture's population had already been on the decline since before the nuclear crisis, the number of residents who moved out of the prefecture rose to 32,471 between March and June -- 1.7 times higher than the figure a year earlier. Including those who had not shifted their residence certificates from Fukushima to where they live now, 55,793 residents had evacuated out of the prefecture as of Aug. 25.

The nuclear disaster has also cast a shadow on Fukushima's economy and employment. The industrial output index dropped to 86.1 in June from the 2005 level of 100. Although the figure has recovered from the 79.9 recorded in May, it still fell shy of the level of 95.8 marked in February before the nuclear disaster broke out.

The number of employment insurance beneficiaries came to 23,862 in July, up 1.9 times from the same month last year, while 8,881 people were seeking work as of Aug. 21 after they lost their jobs due to the disaster.

The city of Aizuwakamatsu -- a popular destination for school trips -- saw a steep decline in the number of visitors on school trips, with only 2,506 students from 31 schools coming between April and August. During the same period last year, 43,785 students from 545 schools had visited the city.

Radioactive waste disposal conundrum slowing recovery efforts

A sign in the Fukushima city district of Onami reads: "Waste from outside the Onami district not permitted. Dumping is illegal." Behind it, radiation-tainted waste wrapped in linen bags is stacked together and surrounded with sandbags to prevent the spread of radioactive materials, on Sept. 5. (Mainichi)

FUKUSHIMA -- The law had not anticipated the radioactive contamination beyond the gates of nuclear power plants, and has left not only Fukushima Prefecture but also municipalities in the Tokyo metropolitan area with radiation-tainted waste that has no place to go. The road to resolution and recovery remains bumpy, despite a special measures law implemented in response to the disaster at the Fukushima No. 1 nuclear plant.

In Fukushima Prefecture, the need to decontaminate residences and roads has become increasingly urgent, while little headway has been made in securing temporary storage for radiation-tainted mud. And while the central government is hoping to set up interim storage facilities in the prefecture, no concrete timeline has been established. In addition, rubble still litters Japan's northeastern coast.

Part of the Kamioguni district of the Fukushima Prefectural city of Date has been designated a "hot spot" where radiation exposure could exceed 20 millisieverts per year, and residents there are worried about leaving radioactive waste around without proper facilities.

"What if it contaminates the well water?" said Yasuo Kanno, 74, a local district leader, as he watched water drip from a faucet in his home. He decided to stay back even after the government issued an evacuation advisory in the area.

The Date Municipal Government has plans to decontaminate the entire city, which will involve the removal of mud and grass from gutters and gardens, where radioactive materials tend to accumulate. And while it is searching for waste storage locations in the five towns that existed before they were incorporated into the city, for the time being residents will be asked to keep the tainted materials on their property.

Residents have been instructed by the city to store the waste in thick plastic bags, preventing the contents from seeping into groundwater. But those who use well water in their daily lives are not convinced of the measure's effectiveness.

"We want the decontamination process to take place as soon as possible, and for the young people who have evacuated elsewhere to come back," Kanno said.

Fukushima is the third largest prefecture in the country, with a large area of mountainous terrain. As a result, use of water mains stands at 92.4 percent of the population -- lower than the national average of 97.5 percent -- leaving many residents, like those in Kamioguni, worried about the effects of radioactive waste on their groundwater.

Securing temporary storage sites for radioactive waste is a problem for urban areas as well. The city of Fukushima is planning to store its radioactive waste on publicly-owned properties, but the only location that it has secured thus far is in the Onami district, far from the city center. The 7,000-square-meter city-owned property is located 180 meters from the nearest private residence.

"It was a difficult decision to accept the city government's plan, and we don't want to allow the city to dump contaminated waste from other areas here," said a 60-year-old member of the local neighborhood association.

The central government announced on Aug. 26 that "for the time being, it is realistic for cities, towns, villages and communities to set up temporary storage space for tainted waste that is left over from decontamination measures." While the government's nuclear disaster headquarters is aware that local governments are having difficulty securing temporary storage sites, it says, "We have no choice but to ask each municipality to make those decisions."

Little headway has been made in securing sites for interim radioactive waste repositories or in designing such facilities, leaving municipal officials at the front lines of the recovery effort dissatisfied with the central government's performance.

"The government will likely force interim storage facilities onto the communities close to the nuclear power plant, where the chances of residents being able to return home are slim," one said.

"It will take quite some time before (the government) earns the understanding and cooperation of residents," said a different municipal official, while another commented, "It's like we're just running and running despite the lack of a visible goal."

Meanwhile, the disposal of radiation-tainted rubble along the coast has also run into trouble. There is an estimated 610,000 metric tons of rubble in the Fukushima Prefectural city of Minamisoma. The 400,000 tons of rubble found in parts of the city not designated as no-entry zones have been gathered in nine locations. In late August, the national government finally issued guidelines on how to handle ash produced from incinerating waste. A city official said, however, that municipalities are overwhelmed.

"There's so much rubble that the separation of waste takes a long time. We don't know when we'll be able to get going on incineration or hauling waste to treatment facilities."

Cheap radiation detectors give inaccurate results, consumer watchdog reports

Nine types of low-price radiation detectors on the market, some now being used to monitor radiation in the Tokyo area, give incorrect measurements, the National Consumer Affairs Center of Japan (NCAC) announced on Sept. 8.

The NCAC purchased the nine radiation detectors, all priced at less than 100,000 yen and all believed to have been made in China, on Internet shopping sites. When used to measure atmospheric radiation the detectors displayed results as much as four times higher than devices known to meet international standards, and also failed to measure radiation emissions of 0.06 microsieverts per hour or less correctly.

When exposed to radioactive cesium 137, the detectors displayed results far lower than actual radiation levels, in some cases delivering figures more than 30 percent off the genuine emissions.

"These cheap devices are not accurate, and cannot be used to check radiation in food or drink," an NCAC official stated.

The nine models tested were: AK2011, BS2011+, DoseRAE2 PRM-1200, DP802i, FJ2000, JB4020, RAY2000A, SW83 and SW83a. Of these, the Tokyo Metropolitan Government has bought 70 DoseRAE2 PRM-1200 detectors. Two of the devices have been distributed to each of the local governments within metropolitan Tokyo to measure atmospheric radiation. A representative of the

environment and hygiene section of the metropolitan government's health and welfare bureau told the Mainichi, "We are lending out the detectors to local governments after telling them that they can't use them for anything but the simplest of measurements."

US quake exceeded nuclear plant design

The earthquake that hit the eastern US in August caused shaking beyond what nuclear plants in the area are designed to withstand.

The operator of the North Anna nuclear plant, located some 20 kilometers from the quake's epicenter in central Virginia, reported the finding at a hearing of the Nuclear Regulatory Commission on Thursday.

The plant lost external power and saw its back-up generators kick in when the magnitude-5.8 earthquake struck on August 23rd.

At the hearing, the plant operator said the shaking did not continue long enough to cause any serious damage.

The NRC said it is the first time for an operating nuclear plant in the US to be hit by an earthquake exceeding its designed strength.

The commission plans to carefully consider the need for new measures to protect against future tremors and may reassess seismic risks at all the country's nuclear plants.

The last time Virginia was hit by an earthquake of magnitude 5 or more was 114 years ago, in 1897.

The latest quake has raised concerns over the seismic resistance of nuclear power plants on the US east coast, where experts until now believed that major tremors were unlikely to occur.

Friday, September 09, 2011 18:21 +0900 (JST)

Six months later: The Fukushima nuclear disaster in retrospect

As Japan approaches the six-month anniversary of its worst nuclear disaster, when an unprecedented meltdown occurred in three of the Fukushima No. 1 Nuclear Power Plant's reactors in a combination of natural and manmade calamities, the road to recovery is still long and unclear. In anticipation of the anniversary, the Mainichi looks back over the past six months to outline what has been done, learned, and where Japan currently stands on the issue in this time of crisis.

On March 11, a magnitude 9.0 earthquake followed by a series of tsunami waves -- the worst in the history of Japan -- severely damaged the Tokyo Electric Power Co. (TEPCO)-operated Fukushima No. 1 nuclear complex, located along the coast of the towns of Futaba and Okuma in Fukushima Prefecture. As a result of the disaster, all external power sources were lost, causing the supply of cooling water to the plant's No. 1, 2 and 3 reactors to stop. Hydrogen was generated as a result of a chemical reaction

between fuel rods and water, leading to hydrogen explosions which badly damaged reactor buildings. The government, which initially estimated the accident level at 4 on the International Nuclear Event Scale (INES), later raised the level to 7 -- the highest rank. This matched the level of the Chernobyl catastrophe, which at that stage was the worst nuclear accident in history.

The next six months were a huge struggle for both TEPCO and the government as they tried to deal with the tainted water. Shortly after the accident, every possible means was employed to inject water into reactors and spent nuclear fuel pools in a desperate effort to cool down nuclear fuel. Self-Defense Forces helicopters, fire engines and pumping vehicles were mobilized to inject sea water into the reactors and spent fuel pools. However, the injected water started piling up within reactor buildings, creating a mass of water contaminated with huge amounts of radiation. The water began to leak from the damaged containment vessels and piping.

At the end of March, water contaminated with high levels of radiation was found in a tunnel connecting the buildings housing the No. 1 to 3 reactors with the ocean. The water contained about 40,000 times the amount of water in reactors. Workers managed to prevent the water from leaking into the sea through a stopgap measure. However, as long as water continued to be injected into the reactors, the amount of radioactive water would only increase and overflow. Haruki Madarame, chairman of the Cabinet Office's Nuclear Safety Commission of Japan, said neither the government nor the power supplier has the expertise to treat water contaminated with high levels of radiation, suggesting that they were not prepared to respond to any accident beyond the scope of their assumption.

According to the Nuclear and Industrial Safety Agency, contaminated water leaked into the ocean at least twice. The first instance occurred between April 1 and 6 at the No. 2 reactor, when 520 cubic meters was released; the second, between May 10 and 11 at reactor No. 3, when a total of 250 cubic meters of water was released into the open sea.

In a desperate effort to prevent further leaks, workers were forced to shift contaminated water into any tank on the premises of the plant that had some available capacity. While releasing 10,000 cubic meters of relatively low-level radioactive water into the sea, TEPCO shifted more water to neighboring facilities, and even purchased a nearby man-made floating island known as "Megafloat," capable of holding up to 10,000 cubic meters of water and transported it to an area near the power plant.

Meanwhile, in its action plan released in April, TEPCO announced that it would cool down the reactor cores by filling their containment vessels with water. Even though the utility thought it would be an effective way to cool down the reactor cores, the water did not reach the level that was considered necessary to cool down the reactors. In May, a hole was discovered in one of the containment vessels -- from which injected water was leaking, forcing TEPCO to abandon the method. As a result, contaminated water was continuing to build up within the power plant. As of the end of August, there was a total of 90,000 cubic meters of water stored in the reactor and turbine rooms of the plant's No. 1 to 4 reactors. Counting the water stored in other facilities, the figure stood at about 113,000 cubic meters -- enough to fill some 570,000 drums.

Following the failure of its initial plan, TEPCO then released a new one, announcing that the company would attempt to remove all radioactive materials from the contaminated water and reuse the purified water to cool down the reactor cores. The method would allow the utility to continue to cool down the reactors while preventing the amount of radioactive water from increasing further. TEPCO created a water purification system by combining machines produced by U.S.-based Kurion Co. and Areva Co.

headquartered in France and other firms, which was put in full operation in June. In addition, the Toshiba-manufactured machine SARRY (Simplified Active Water Retrieve and Recovery System) was added in order to increase the system's capacity to remove radioactive materials from the contaminated water.

The government hoped that if the plan was successful, it could lift emergency evacuation preparation orders for areas lying between 20 and 30 kilometers from the plant. However, a series of minor accidents, including temporary malfunctions and leaks from the 4-kilometer-long hose used to carry the water, slowed down the operation, and the operations of the system has not yet been stabilized. According to official data, 32 mishaps with the water purification system had occurred by mid-August.

"The lack of preparation and vision on how to deal with this crisis is a major point of regret," says Yoichi Enokida, a professor of nuclear chemical engineering at Nagoya University. "The lack of objective views of the operation rate of the newly adopted nuclear waste removal system has only contributed to everyone's rising distrust of nuclear power as a way of generating electricity."

7-year-old boy worked in restricted radiation zone at Fukushima No. 2 plant

A 17-year-old boy worked in a restricted radiation zone at the Fukushima No. 2 nuclear plant for five months in 1993-1994, plant operator Tokyo Electric Power Co. (TEPCO) revealed on Sept. 9.

The restricted zone experiences higher levels of radiation than other areas of the plant, and the Labor Standards Act forbids work in the zone for people under 18. TEPCO, which has reported the five-month stint by the minor to the Nuclear and Industrial Safety Agency, stated that the boy had lied about his age and obtained a radiation tracking booklet (used by nuclear workers to monitor their cumulative exposure). The boy worked at the plant from September 1993 to January 1994.

The violation came to light in late August this year when the same person applied to work in the same restricted zone again. TEPCO staff noticed that the birthday on the person's ID was different than the one recorded in 1993.

Nuclear experts discuss radiation in Fukushima

Nuclear experts from around the world have exchanged views on how to provide information about radiation exposure.

Some 40 experts from 14 countries are taking part in the 2-day meeting in Fukushima City, Fukushima

Prefecture.

The symposium was organized by the Nippon Foundation in cooperation with the International Commission on Radiological Protection. The body provides guidance and recommendations on protection from radiation.

An US epidemiologist, John Boice, said he does not think people's health will be affected by the Fukushima accident. He said Japan prevented contaminated food from being distributed, unlike what happened after the Chernobyl accident.

Boice said counseling and timely information are essential for those worried about radiation in food.

The participants discussed ways to provide information on radiation exposure. Some said the radiation levels following the Fukushima accident should have been made public as they were much lower than the levels deemed safe by scientists.

There was also a suggestion that comparative data with other risks such as traffic accidents should have been made available.

Makoto Akashi, whose organization is co-sponsoring the gathering, said he hopes to find ways to convince people that there will be no health impact from radiation from the Fukushima accident.

The experts will compile recommendations on ways to resolve the Fukushima accident including how to limit possible radiation exposure.

Sunday, September 11, 2011 22:59 +0900 (JST)

High levels of radiation found in remote areas

Japan's science ministry has compiled a map showing radiation levels in Fukushima and 4 surrounding prefectures, based on the results of an aerial survey.

Removal of radioactive substances will be required in the affected areas.

In the map, levels of radioactivity at locations one meter above the ground are highlighted in different colors.

Red is for areas where the radiation level is 19 microsieverts per hour or higher.

The red band spreads from the crippled Fukushima Daiichi nuclear power plant to the northwest and extends about 30 kilometers.

Areas with radiation levels of 3.8 microsieverts per hour or above are highlighted in yellow. The figure translates to above 20 millisieverts per year, a threshold in designating an evacuation zone. The yellow area extends beyond the current evacuation zone.

Light green shows levels between 0.5 and one microsieverts per hour. They still are far beyond the annual level of one millisievert which is believed to cause no harm to people. Much of Fukushima

Prefecture, southern parts of Miyagi Prefecture, and northern parts of Tochigi and Ibaraki prefectures lie in this zone.

Sunday, September 11, 2011 10:49 +0900 (JST)

Japan to report to IAEA on efforts to enhance nuclear regulation

TOKYO (Kyodo) -- Japan will report to the International Atomic Energy Agency later this month its latest efforts to improve its nuclear regulatory system, including plans to create a new nuclear safety agency and a nuclear safety training institute, the government said Sunday.

"We would like to show how we are working on regulation issues," nuclear disaster minister Goshi Hosono told a press conference after the government endorsed a new report on the crisis at the Fukushima Daiichi power plant, which will soon be submitted to the U.N. nuclear watchdog.

It is the second report compiled by the Japanese government and to be forwarded to the IAEA, detailing the situation at the crisis-hit plant and lessons learned from the disaster. The latest report will be presented at a side event of the IAEA general conference on Sept. 19.

In an outline of the report, the government touched on its decision made last month to separate the Nuclear and Industrial Safety Agency from the industry ministry by creating a new nuclear regulatory body under the Environment Ministry by April next year.

The move came as public confidence in the current nuclear regulatory body was shaken by its failure to prevent the disaster at the Fukushima plant, while major criticism focused on problems caused by having regulators under the industry ministry, which also promotes nuclear power.

The report stressed the "vital importance" of training more nuclear safety personnel to respond to another nuclear crisis and referred to an idea to establish what it tentatively called an International Nuclear Safety Training Institute.

The institute, the creation of which should be deliberated by the new government nuclear safety regulatory body to be established by next April, would seek to improve the quality of nuclear regulators within Japan and may also invite people from abroad to contribute to global nuclear safety, the report and a government official said.

The report also said work to contain the crisis is proceeding steadily, but "several more months" are needed to bring damaged reactors to a more stable condition known as "cold shutdown."

Hit by a magnitude-9.0 earthquake and ensuing tsunami on March 11, the Fukushima nuclear plant lost nearly all its power sources, and consequently the ability to cool the reactors and spent fuel pools at the Nos. 1 to 4 units.

As a result, temperatures soared along with a build-up of hydrogen gas, leading to catastrophic explosions which badly damaged three of the four reactor buildings and the release of a large amount of radioactive material in the worst nuclear accident since Chernobyl.

Workers have now installed a new water circulation system to cool the crippled reactors, marking some progress in bringing the plant to a stable condition.

The government and plant operator Tokyo Electric Power Co. seek to achieve a cold shutdown of the plant by January at the latest.

As for long-term issues, the report pointed to the task of removing the melted fuel from the reactors, storing and disposing of it, but did not elaborate.

The utility known as TEPCO separately said Sunday that it has succeeded in reducing the amount of highly radioactive water accumulating in the plant's two reactor turbine buildings to the target level.

(Mainichi Japan) September 12, 2011

2 out of 3 municipalities opposed to more nuclear plants: survey

TOKYO (Kyodo) -- Roughly two out of three municipal leaders in Japan are opposed to building more nuclear power plants while nearly half of local governments are interested in hosting big solar power plants, a Kyodo News survey showed Saturday.

The survey, conducted ahead of the six-month mark of the March 11 earthquake and tsunami, also shows that most are dissatisfied with measures taken by the central government to cope with the crisis at the Fukushima Daiichi power plant crippled by the disasters.

According to the survey of 1,793 prefectural, city, town and village offices, of which 1,697 responded, 38 percent say they are against building new nuclear power plants while 27 percent are not only against building new plants but also want to see the early abolition of existing plants.

It also showed 17 percent say they will allow new plants and reactors when it is confirmed that they will have sufficient safety measures in place while 0.5 percent back the immediate abolition of atomic power plants.

Many respondents call for a more cautious decision-making process on the operation of nuclear plants, with 54 percent backing the suggestion that consent must be secured not only from the host communities but also from those in the vicinity as conditions for constructing a new plant or restarting an idled reactor.

On possible use of renewables in the wake of the Fukushima accident, 47 percent express interest in inviting large-scale solar power plants to their areas.

In a multiple-choice question about the most appropriate natural energy source, 80 percent picked solar energy and 37 percent selected water power, although not involving dams, followed by wind power and biomass, at 34 percent each.

Most of the respondents, or 88 percent, complain about insufficient measures taken by the government to deal with contamination by radioactive substances after the Fukushima Daiichi accident.

In addition, 75 percent do not appreciate ongoing measures taken by the government to reconstruct areas devastated by the disaster, while some 19 percent said that they do.

The survey also showed 33 percent have reviewed or are reviewing their disaster prevention plans and 53 percent plan to do so.

L'accident sur l'installation nucléaire du Gard est "terminé"

LEMONDE.FR avec AFP | 12.09.11 | 13h56 • Mis à jour le 12.09.11 | 17h

Le site nucléaire de Marcoule dans le Gard.Reuters/SEBASTIEN NOGIER

Un four a explosé dans un centre de traitement de déchets faiblement radioactifs, sur le site nucléaire de Marcoule, dans le Gard, lundi 12 septembre, vers midi, causant la mort d'une personne et en blessant quatre autres.

A 16 heures, l'Autorité de sûreté nucléaire (ASN) a indiqué que *"l'accident était terminé"* et *"qu'aucune contamination n'avait été relevée"*. *"Aucune contamination n'a été détectée par nos six balises dans la vallée du Rhône"*, confirme la Commission de recherche et d'information indépendantes sur la radioactivité (Criirad) sur son [site Internet](#). *"Il n'y a pas de risque radioactif ou chimique"*, ajoute le ministre de l'énergie, [Eric Besson](#). *"Il n'y a aucun risque de rejet à venir"*, indique encore EDF.

"Cet accident ne comporte pas d'action de protection des populations. L'ASN suspend son organisation de crise", ajoute l'ASN. *"Aucune mesure de confinement ou d'évacuation"* des salariés *"n'a été nécessaire"* car les blessés *"n'ont pas été contaminés"*, confirme le ministère de l'intérieur. De plus, l'homme décédé est *"mort dans l'explosion"* et non des suites d'éventuels rejets radioactifs. Le salarié

grièvement blessé a été évacué d'urgence vers un hôpital de Montpellier. Les autres, légèrement blessés, ont été dirigés vers l'hôpital de Bagnols-sur-Cèze. La ministre de l'écologie, [Nathalie Kosciusko-Morizet](#), doit se [rendre](#) sur place à 17 h 30.

FUSION DE MÉTAUX RADIOACTIFS

L'explosion, suivie d'un incendie qui a été maîtrisé vers 13 heures, a eu lieu au Centre de traitement et de conditionnement des déchets de faible activité (Centraco) exploité par la société Socodei, filiale d'EDF, et installé sur la commune de Codolet. Ce site s'occupe du conditionnement des déchets de faible et de très faible activité.

La déflagration a touché un four électrique, mis en service en 1999, servant à [diminuer](#) le volume des déchets radioactifs de faible et très faible activité pour ensuite les [conditionner](#). Le four procède par incinération pour les déchets textiles (gants, combinaisons ou encore masques) ou par fusion pour les métaux (vannes, pompes outils, etc.).

"LE BÂTIMENT A GARDÉ SON INTÉGRITÉ"

Au moment de l'explosion, le four contenait 4 tonnes de métaux, dont la radioactivité était de 67 000 becquerels, soit moins de 17 becquerels par kilogramme. *"C'est une activité radioactive très faible, incomparable avec celle d'un réacteur nucléaire"*, explique [Thierry Charles](#), directeur de la sûreté à l'Institut de radioprotection et de sûreté nucléaire (IRSN), joint par Le Monde.fr.

"Le four se trouve dans un local, lui-même contenu dans un bâtiment. Le local a été affecté, mais le bâtiment a gardé son intégrité. Il n'y a donc pas de rejets radioactifs à l'extérieur du bâtiment", poursuit Thierry Charles. L'IRSN a toutefois dépêché une équipe sur place, qui doit [faire](#) lundi des prélèvements – herbe, terre, poussière sur les capots de voiture – qui seront analysés d'ici lundi soir.

UNE ERREUR HUMAINE PEUT-ÊTRE EN CAUSE

Les causes de l'explosion sont pour l'instant inconnues. Selon une source gouvernementale, *"il semblerait y [avoir](#) eu une erreur humaine"*. *"Il peut aussi s'[agir](#) d'une fuite d'eau qui a réagi avec le métal en fusion, ou bien d'un déchet contenu dans le métal qui aurait provoqué une réaction"*, ajoute Thierry Charles.

Le directeur général de l'Agence internationale de l'énergie atomique (AIEA) a annoncé [avoir](#) demandé des informations à la France concernant l'explosion, conformément à la procédure classique. L'accident sera suivi de près par la Commission européenne en lien avec les autorités françaises, a ajouté l'exécutif communautaire.

Greenpeace, [comme d'autres militants écologistes](#), a réclamé aux autorités une transparence totale et immédiate sur cet incident. *"Il est indispensable que les populations locales soient informées en temps réel sur la situation et sur les éventuels rejets radioactifs"*, a déclaré [Yannick Rousselet](#), chargé de campagne nucléaire à Greenpeace France.

France nuclear: Marcoule site explosion kills one

<http://www.bbc.co.uk/news/world-europe-14883521>

One person has been killed and four injured, one seriously, in a blast at the Marcoule nuclear site in France.

There was no risk of a radioactive leak after the blast, caused by a fire near a furnace in the Centraco radioactive waste storage site, said officials.

The owner of the southern French plant, national electricity provider EDF, said it had been "an industrial accident, not a nuclear accident".

The cause of the blast was not yet known, said the company.

The explosion hit the area at 11:45 local time (09:45 GMT). A security cordon was set up as a precaution.

But interior ministry spokesman Pierre-Henry Brandet later said there had been no leak of radiation, neither inside nor outside the plant.

None of the injured workers was contaminated by radiation, said officials. The worker who died was killed by the blast and not by exposure to nuclear material.

The Centraco treatment centre belongs to a subsidiary of EDF. It produces MOX fuel, which recycles plutonium from nuclear weapons. There are no nuclear reactors on site.

The EDF spokesman said blast happened in a furnace used to burn waste, including fuels, tools and clothing which had been used in nuclear energy production but had only very low levels of radiation.

"The fire caused by the explosion was under control," he said. Another official later said the incident was over.

The International Atomic Energy Agency (IAEA) said it was in touch with the French authorities to learn more about the nature of the explosion.

Speaking on the sidelines of a scheduled meeting of the IAEA's board, Director General Yukiya Amano said the organisation's incident centre had been "immediately activated".

France's Environment Minister Nathalie Kosciuscko-Morizet visited the site on Monday, to "help carry out a precise evaluation of the possible radiological impact of this accident".

"For the time being, no exterior impact has been detected," the AFP news agency quoted a ministry spokesman as saying.

"There are several detectors on the outside and none of them detected anything, the building is sound."

Stress tests

Marcoule was opened in **1955** and is **one of France's oldest nuclear sites**, though it has been extensively modernised.

It is located in the Gard department in Languedoc-Roussillon region, near France's Mediterranean coast.

Marcoule is one of France's oldest nuclear facilities but has no reactors on site

All the country's 58 nuclear reactors have been put through stress tests in recent months, following the disaster at Japan's Fukushima nuclear plant which was hit by an earthquake and tsunami.

EDF's share prices fell by more than 6% as news of the blast emerged.

France is the world's most nuclear-dependent country, relying on nuclear power to meet 75% of its energy needs, so safety in the industry is a highly sensitive issue, says the BBC's Christian Fraser in Paris.

In June, France announced it was investing 1bn euros (£860m) in nuclear power, including a significant boost for safety research.

French nuclear giant Areva is developing the next generation of nuclear reactors and has been involved in a huge publicity campaign since the Fukushima disaster to reassure the public of the safety of nuclear energy.

Other countries in Europe, including Germany, Italy and Switzerland, have said they will reduce or phase out their use of nuclear power over the next few years.

1 dead in explosion at French nuclear plant

PARIS (AP) -- The French nuclear safety body says one person died and another was seriously injured Monday in an explosion at the Marcoule nuclear site in southern France.

The Nuclear Safety Authority said there have been no radiation leaks outside of the plant, which treats nuclear waste with little radioactivity.

Three other people were injured in the explosion, the statement said.

Staff at the plant reacted to the accident according to planned procedures, it said.

The Marcoule site is located in Languedoc Roussillon, in southern France, near the Mediterranean Sea.

(Mainichi Japan) September 12, 2011

Explosion occurs at French nuclear facility

The French nuclear safety agency says an explosion occurred at a nuclear processing plant in the suburb of Nimes in southern France on Monday.

The blast took place at a furnace in the nuclear waste processing center in Marcoule.

One person reportedly died and 4 others were injured.

Officials at the facility say there has been no radioactive leaks, and that there is no reactor at the site.

Local media say no evacuation orders have been issued for residents living near the facility.

The nuclear safety authority says nuclear waste is processed at the facility.

A fire that broke out briefly has been extinguished.

The nuclear safety authority is investigating how the blast occurred.

Monday, September 12, 2011 22:19 +0900 (JST)

Blast at French nuclear site kills 1, injures 4

PARIS (AP) -- An explosion at a nuclear waste facility in southern France has killed one person and injured four others. Authorities said there was no radioactive leak, but critics urged France to rethink its nuclear power in the wake of the catastrophe at Japan's Fukushima plant.

The Nuclear Safety Authority declared the accident "terminated" soon after the blast Monday at a furnace in the Centraco site, in the southern Languedoc-Roussillon region, about 20 miles (32 kilometers) from the city of Avignon. One of the injured suffered severe burns.

The agency said the situation had been brought under control in less than an hour after it broke out shortly past noon. The building that houses the furnace wasn't damaged, no leaks were reported and residents who live near the site were not evacuated, the agency said in a statement.

The cause of the accident is not known, and an investigation has been opened to see what went wrong, authorities here said.

France is the world's most nuclear-dependent nation. It relies on the 58 nuclear power plants that dot the country for about three-quarters of its total electricity, and it's also a major exporter of nuclear technology throughout the world.

While the March meltdown at Japan's Fukushima plant prompted other countries to re-evaluate their nuclear programs - with neighboring Germany vowing to shut all its plants by 2022 - France has remained steadfast in its support for nuclear energy.

Authorities here downplayed the importance of Monday's incident.

"It's an industrial accident and not a nuclear accident," Industry Minister Eric Besson said on i-Tele television. "There have been no radioactive leaks and there have been no chemical leaks."

Still, French environmentalists have long called for an end to the country's nuclear program, and several ecology and leftist parties urged authorities here to rethink nuclear policy after Monday's incident.

Sophia Majnoni, who runs Greenpeace's nuclear campaign in France, noted that **the plant was not part of a French safety audit conducted in the wake of the Fukushima accident.**

"It is a nuclear plant yet its resistance to earthquake or flooding won't be checked, which allows us to think that the government has not drawn all the lessons from the Fukushima catastrophe," she said. "It is not only the nuclear power plants that are dangerous for population."

Ecology Minister Nathalie Kosciusko-Morizet was slated to visit **Centraco** - one of four industrial installations at the Marcoule nuclear site - later Monday. The 300-hectare (740-acre) **Marcoule site also houses a research center and four industrial sites, including one that makes Mox**, a fuel made from plutonium and uranium.

France's EDF electric power company, whose subsidiary operates Centraco, said the furnace in Monday's accident is used to melt slightly radioactive metal waste, including gates, pumps and tools into easy-to-store bars.

The furnace went into service in 1999, EDF said, and **treats mostly waste from EDF's own power plants, as well as a small amount of material from hospitals or medical research labs.** Nothing comes from weapons manufacture, company spokeswoman Carole Trivi said.

The person killed was a foundry worker who was near the furnace when it exploded. The prognosis for the seriously injured worker, evacuated to a hospital in nearby Montpellier, was not immediately known.

None of those involved in the accident were exposed to radiation, the nuclear safety agency said.

The head of the Vienna-based International Atomic Energy Agency, Yukiya Amano, said his organization's "incident and emergency center was immediately activated and has sent requests for detailed information."

Nuclear power is big business in France. EDF and state-owned nuclear giant Areva have built reactors the world over and inked recent deals to build Poland's first nuclear plant and to create a joint-venture with a Chinese nuclear company. France also treats nuclear waste from around the globe. Japan's March 11 tsunami and the disaster at the Fukushima nuclear plant didn't spark the kind of soul-searching over reliance on nuclear energy in France that it did in other countries, including neighboring Germany. There, eight older reactors were quickly taken off the grid, and the nine remaining plants are to close over the coming decade.

France's President Nicolas Sarkozy appeared to dig in his heels in the wake of the Japanese meltdown, pledging as recently as June to stick to a plan to invest 1 billion euros (\$1.37 billion) in future nuclear reactors.

James Acton, an expert in nuclear policy at the Carnegie Endowment for International Peace, said that - **provided the information from French authorities was correct** - the accident appeared not to be very serious

Acton said the biggest concern in the coming hours will be to monitor whether any radiation is released. That will depend in large part on where exactly the furnace is on the site and how well contained it is.

If EDF's assurances that no radiation has escaped so far and that the building around the furnace is intact prove correct, Acton said it would be considered "an industrial accident that happened to contain radioactive material" - and far less serious than an accident involving nuclear fuel.

Asked whether he thought the Monday's accident could sway public opinion in France, Acton said it was "unlikely."

"French public opinion has been robust to date about nuclear," he said. He also noted that even without nuclear power, waste treatment facilities like the one at Centraco would still need to exist to handle medical waste and other sources of radioactivity.

(Mainichi Japan) September 13, 2011

Nuclear agency's safety plan irks Germany, others

VIENNA (AP) -- A post-Fukushima nuclear safety plan prepared by the International Atomic Energy Agency has strained traditional alliances, with the United States comfortable with a watered down plan pushed by Russia and China and objected to by Washington's normal allies.

Germany on Monday was unusually outspoken in expressing its unhappiness with the voluntary nature of undertakings outlined in the IAEA paper, which was authorized in June by a special conference of government ministers and other officials from the agency's 151 member nations.

The plan -- up for passage Tuesday by a 35-nation IAEA board meeting -- "does not fully meet our expectations," Ruediger Luedeking, Germany's chief IAEA representative, told the board.

Suggesting that the text was vague and too nonbinding in nature, Luedeking said Germany would have wanted a plan where member states' commitments to peer reviews and IAEA oversight of their civilian nuclear programs had been "more clearly and stringently set out."

A diplomat from another IAEA member state familiar with the issue said that several EU states beside Germany, Canada, Australia and New Zealand were also unhappy with what they consider the lack of teeth in the "IAEA Action Plan on Nuclear Safety."

Some of their concerns would be voiced on Tuesday, ahead of likely passage of the plan by the board by acclamation or -more likely -- by a vote, he said, asking for anonymity because his information was privileged.

Russia, China, India, Pakistan and Argentina were chief opponents of giving the IAEA more authority to police nuclear safety, said the diplomat.

But the United States was also comfortable with the decision to strip the plan of language entrusting the agency with more clout that was present in earlier drafts and leaving oversight to governments, national safety authorities and power companies, he said. Such a stance reflects Washington's strong belief in domestic regulatory bodies having full control of nuclear safety.

The six-page document outlines steps to be taken by states with civilian nuclear programs to establish weaknesses in their networks and remedy them. But these measures -- whether they are peer reviews, IAEA safety checks, or other proposals meant to improve nuclear safety -- can only be carried out "upon request" of the nation involved.

Instead of being required to do so, member states are "strongly encouraged to voluntarily" open their facilities to outside checks of potential weak links that could result in a nuclear disaster.

IAEA chief Yukiya Amano was spirited in his defense of the plan, saying the steps it outlined to strengthen international cooperation and information exchange were "clearly a step forward" compared to what existed before March 11 earthquake and tsunami that devastated Japan's coastal Fukushima No. 1 Nuclear Power Plant and prompted the action plan.

At the same time he indirectly acknowledged that its effectiveness would depend on willingness by IAEA member countries to implement it -- the voluntary component that its critics object to.

"Every country is expected to support this action plan," he told reporters. "We need to do it now. We cannot postpone."

(Mainichi Japan) September 13, 2011

French envoy says no radiation leak from blast

A French envoy to the UN nuclear watchdog says there is no radioactive leakage after an explosion at a nuclear waste processing facility in southern France.

France's ambassador to the International Atomic Energy Agency, Florence Mangin, confirmed that there was an explosion but said it was not a nuclear accident and no radiation has leaked.

Mangin is attending an IAEA board meeting in Vienna, Austria.

She said the French government will send an emergency response team to the site to gather further information.

France's interior ministry says the explosion was an industrial accident, not a terrorist attack.

Tuesday, September 13, 2011 05:55 +0900 (JST)

France probes explosion at nuclear-related site

Authorities in France say radiation levels around the nuclear waste processing facility where an explosion occurred are normal. They add that the furnace did not explode.

The explosion happened on Monday in Marcoule, southern France, at a building housing a facility to melt low-level radioactive waste. One worker was killed and 4 others were injured in the accident.

According to the facility, the blast was not in the furnace, as initially presumed, but near the furnace.

The French Institute for Radioprotection and Nuclear Safety says radiation readings in the air around the facility are the same as before the accident. No evacuation order has been issued for nearby residents.

The country's nuclear regulatory authority has sent an emergency response team to the site to investigate the cause of the accident.

The ecology minister Nathalie Kosciusko-Morizet has gone to the site to assure residents that there is no nuclear leak.

Observers say the French government is trying to reassure the public. There has been growing concern over nuclear power stations in France following the accident in March at Japan's Fukushima Daiichi plant.

Tuesday, September 13, 2011 07:15 +0900 (JST)

German media report French explosion harshly

German media have reported harshly Monday's explosion at a nuclear waste treatment site in southern France, which killed a worker onsite.

German newspaper, Die Welt, called it the first major nuclear accident since the crisis at the Fukushima Daiichi nuclear plant in Japan.

The daily says that French ministers are calling it an industrial, not a nuclear accident, but that there is no doubt it happened in the country's nuclear industry.

German weekly magazine, Der Spiegel, meanwhile highlights differences between the 2 countries in their energy policies.

Germany decided this year to shut down all its nuclear power plants.

The magazine says the accidents in Chernobyl and Fukushima did not change French attitudes toward nuclear energy, so the latest one will not either.

The magazine criticizes the **slowness of the French nuclear safety authorities in disclosing information, and their response to the accident, describing it as very passive.**

Tuesday, September 13, 2011 12:02 +0900 (JST)

French institute examines radioactive samples

A French nuclear institute says metals containing 67,000 becquerels of radioactive substances were being burned at a nuclear waste treatment site near Nimes in southern France when an explosion occurred there on Monday.

The Institute for Radioprotection and Nuclear Safety says that the radioactive level is so low that there is no possibility of anything hazardous leaking into the environment.

It says the building housing the furnace has not been damaged, and there is no need for residents around the plant to evacuate.

But the institute says as **wind was blowing from north to south at the time of the accident**, it is now examining radioactive levels at several locations in the south of the compound.

The institute says the results will be available within a few hours.

It also says a fire broke out immediately after the explosion, but has been extinguished.

The institute monitored the impact of highly radioactive substances on the sea, after the explosion at Japan's Fukushima Daiichi nuclear power plant in March.

Tuesday, September 13, 2011 05:55 +0900 (JST)

EPCO submits more redacted Fukushima nuke plant manuals to Diet committee

Tokyo Electric Power Co. (TEPCO), operator of the Fukushima No. 1 nuclear plant, has handed a Diet science committee another heavily redacted accident manual for the stricken plant.

The House of Representatives Special Committee on Promotion of Science and Technology and Innovation had requested TEPCO submit two operating manuals -- one each for accidents and severe accidents -- through the Economy, Trade and Industry Ministry (METI). On Sept. 7, the committee announced it had received only the first of the two manuals, the majority of which had been blacked out, prompting the body to demand TEPCO resubmit both manuals by Sept. 9.

The committee revealed on Sept. 12 that the severe accident manual subsequently handed over by TEPCO was also almost entirely redacted.

Meanwhile, at a meeting of the committee's directors on the same day, representatives of METI's Nuclear and Industrial Safety Agency (NISA) revealed for the first time that under the laws governing nuclear power in Japan, the committee has the power to order TEPCO to disclose the manuals in full. As such, the committee requested the minister of economy, trade and industry issue such an order to the utility -- a legal first. The request marks the fourth time the committee has demanded TEPCO disclose the manuals.

"It is unacceptable for TEPCO to refuse to disclose these materials in the wake of this kind of disaster," committee chair Hiroshi Kawauchi said. "Furthermore, the fact that NISA knew there were legal grounds to demand the documents' disclosure but did nothing about it angered many of the committee directors."

Meanwhile, a TEPCO representative stated, "These manuals are entirely internal documents pertaining to the operation of the reactors. They are not for general publication."

NISA and TEPCO representatives brought copies of the three-page severe accident manual to the board of directors meeting. However, only two lines of the document -- one reading "firefighting" and the other "inert gases" -- remained visible. Neither NISA nor the TEPCO representatives provided an explanation for the redactions at the meeting. The utility also collected the blacked-out documents at the meeting's end, saying only, "The issue here is the protection of nuclear materials, and our intellectual property rights."

(Mainichi Japan) September 13, 2011

Spent nuclear fuel holds key to restart of Hamaoka nuclear plant: Shizuoka governor

Shizuoka Prefecture Gov. Heita Kawakatsu said on Sept. 12 that the Hamaoka Nuclear Power Plant should not be restarted until it becomes clear how to deal with spent nuclear fuel kept at the nuclear facility in remarks that could force further delay in resumption of the nuclear reactors there.

Gov. Kawakatsu said at a regular news conference, "The Hamaoka nuclear plant should not be restarted until ways of disposing of spent nuclear fuel become clear." It was the first time Kawakatsu had made the solution to the problem of spent nuclear fuel a condition for the resumption of the nuclear power plant in Omaezaki, Shizuoka Prefecture.

Kawakatsu had previously said he would endorse a plan to resume operations of the nuclear power plant if the prefectural government confirms the safety of anti-tsunami measures taken by Chubu Electric Power Co., the operator of the nuclear facility.

While the prefectural government does not have legal authority to decide whether to restart the nuclear power plant, Chubu Electric has said it will respect the intention of local residents and governments. Chubu Electric had planned to restart the nuclear plant when it got its anti-tsunami measures ready. But the new condition will make it increasingly unclear when the nuclear power station can actually be restarted.

There are a total of 6,625 spent nuclear fuel rods kept at the Hamaoka Nuclear Power Plant, and Chubu Electric plans to ask the nuclear waste reprocessing plant in the village of Rokkasho, Aomori Prefecture, to dispose of the used fuel rods. The reprocessing plant had been scheduled to be fully operational in autumn of 2012.

But even the test operation of the reprocessing plant has been suspended following the outbreak of the nuclear crisis at the Fukushima No. 1 Nuclear Power Plant, and therefore it is not clear whether the plant will begin its operation as originally scheduled. "We are not in a situation where we can take the spent nuclear fuel to the village of Rokkasho. I want to present things like that to Chubu Electric," said Gov. Kawakatsu.

Schroeder: Japan can form energy policy without nuclear power

BERLIN -- Former German Chancellor Gerhard Schroeder said Japan is technologically capable of establishing a non-nuclear-based energy policy and could become a pioneer in sources of energy other than nuclear power.

The former chancellor, who played a leading role in passing legislation to phase out nuclear power in Germany in 2002, made the comments in an interview with the Mainichi as Japan marked six months since the onset of the ongoing crisis at the Fukushima No. 1 nuclear plant.

"Japan is in a position where it is technologically capable of forming different energy policies," Schroeder said, adding that when Germany decided to eliminate nuclear power, "there was tremendous resistance from the power industry, which had believed that nuclear power was the essence of their business model, but debate was continued with industry executives until they understood." In making the comment, Schroeder stressed the importance of political leadership in forming new policy.

In Europe, countries can import electricity from their neighbors if they run short, but Japan, being an island nation, is unable to rely on other nations. However, Schroeder said that by working to conserve energy, expanding forms of renewable energy such as solar and wind power, and temporarily using energy such as natural gas, which contributes less to global warming, "Japan could become a pioneer in energy other than nuclear power."

Since the outbreak of the Fukushima nuclear crisis, most developed countries, as well as emerging and developing countries concerned about shortages of electricity, have continued to rely on nuclear power, on condition that safety is enhanced.

Commenting on events that could threaten the safety of nuclear power plants, Schroeder said, "Even risks of less realistic dangers like terrorism or airplane accidents must not be ruled out if there is even a slim possibility of them happening."

"Germany's safety philosophy is more solid than that of Japan," Schroeder added.

Pointing to Japan's failure to predict the tsunami that caused the nuclear crisis in Fukushima Prefecture, he said, "The massive tsunami could probably have been envisaged, and the fact that it was not envisaged when it should have been is problematic," he said.

In 1998, Schroeder's Social Democratic Party of Germany formed a coalition with the German Green Party. In 2002, the coalition passed legislation to eliminate nuclear power by around 2020.

The administration of Angela Merkel had put this policy on hold, but after the accident at the Fukushima No. 1 Nuclear Power Plant, quickly returned to the line of eliminating nuclear power. The administration decided to cease operation of all 17 nuclear power plants in Germany by 2022, a move approved by the German parliament.

Edano: Create society not reliant on nuclear power

Economy and industry minister Yukio Edano says Japan should become a society that can live without nuclear power before it can have a national debate on the need for such energy.

Edano was giving his first news conference since taking office on Monday.

He said the swift development of alternative power sources and the promotion of energy saving measures could lead to a society that does not rely on nuclear power.

He said a public debate on the necessity of nuclear plants should be initiated at that time.

Edano also called on Japan to keep reducing gas emissions, but said there should be a fresh discussion of its stated target of a 25 percent cut from the 1990 level by 2020.

He said the emissions target should be reconsidered as Japan reviews its energy policy following the accident at the Fukushima Daiichi nuclear power plant.

Referring to possible power shortages this winter, Edano said the government hopes to allow some of the country's idled nuclear plants to be restarted.

Tuesday, September 13, 2011 05:55 +0900 (JST)

Nuclear agency's board adopts safety plan

VIENNA (AP) -- A 35-nation meeting of the U.N. nuclear agency on Tuesday adopted a post-Fukushima nuclear safety plan -- despite gripes by influential member nations that it was too timid in making compliance voluntary.

Germany and several other EU states -- as well as Canada, Australia, Singapore and New Zealand -- are unhappy with the plan because **it does not obligate countries to allow outside monitoring of their civilian nuclear programs and gives the International Atomic Energy Agency no enforcement powers on safety.**

Board member nations adopted the document by consensus, but not before Canada aired grievances shared by other critics in an unusually blunt statement.

"The draft Action Plan before Governors today will be seen as a timid response by the Agency," said Canada's statement to the closed meeting.

Canada said the plan is neither as comprehensive as recommended by a special post-Fukushima IAEA conference attended by dozens of government ministers in June, nor recommendations by IAEA chief Yukiya Amano.

"It is disappointing, therefore, that the draft contains few new commitments and little in the way of increased transparency or safety peer reviews," said the statement, which was made available to The Associated Press.

It chastised both the agency and its member states for **missing "an opportunity to make necessary reforms to the global nuclear safety framework."**

Earlier in the debate on the plan, which began Monday, Ruediger Luedeking, Germany's chief IAEA representative, said the document "does not fully meet our expectations."

Suggesting that the text was vague and too nonbinding in nature, Luedeking said Germany would have wanted a plan in which member states' commitments to peer reviews and IAEA oversight of their civilian nuclear programs had been "more clearly and stringently set out."

Russia, China, India, Pakistan and Argentina were chief opponents of giving the IAEA more authority to police nuclear safety, said a diplomat from an IAEA member state attending the meeting.

But the United States was also comfortable with the decision to strip the plan of language entrusting the agency with more clout that was present in earlier drafts and leaving oversight to governments, national safety authorities and power companies, he said. Such a stance **reflects Washington's strong belief in domestic regulatory bodies having full control of nuclear safety.**

The six-page document outlines steps to be taken by states with civilian nuclear programs to establish weaknesses in their networks and remedy them. But these measures -- whether they are peer reviews, IAEA safety checks, or other proposals meant to improve nuclear safety -- can only be carried out "upon request" of the nation involved.

Instead of being required to do so, member states are **"strongly encouraged to voluntarily"** open their facilities to outside checks of potential weak links that could result in a nuclear disaster.

(Mainichi Japan) September 14, 2011

Les tests de résistance sur le nucléaire français seront rendus publics

LEMONDE.FR avec AFP | 14.09.11 | 11h14 • Mis à jour le 14.09.11 | 11h17

Eric Besson, le ministre de l'énergie a demandé mercredi à l'Autorité de sûreté nucléaire (ASN) de rendre publics les tests de résistance sur les installations nucléaires françaises.

"Je vous indique que c'est ce jeudi 15 [septembre] que les exploitants doivent répondre à l'ASN en remettant leur rapport, et nous avons souhaité, le premier ministre a confirmé, que l'Autorité de sûreté nucléaire remette publiquement ces rapports à la disposition de quiconque", a déclaré M. Besson sur i-Télé.

"Donc, nous, on ne peut pas avoir, contrairement à ce qu'on a entendu depuis quelques jours, de transparence plus grande", a fait valoir M. Besson, interrogé sur la sécurité des centrales françaises après l'explosion lundi d'un four servant au recyclage de déchets radioactifs à Marcoule (Gard).

Le cabinet du ministre a indiqué que les rapports seraient rendus publics lors de leur analyse par l'autorité nucléaire et avant les éventuelles premières mesures attendues vers la mi-novembre.

Une annonce accueillie favorablement par Areva. *"Areva a toujours soutenu la transparence, qui est une des conditions du développement du nucléaire",* affirme une porte-parole du groupe.

Les tests de résistance concernent notamment les cinquante-huit réacteurs d'EDF ainsi que quatre sites d'Areva, dont l'usine de traitement des combustibles usés de La Hague (Manche), l'usine de fabrication de combustibles recyclés Melox dans le Gard. Le CEA compte, lui, un grand nombre de diverses petites installations.

Après la catastrophe de Fukushima au Japon, survenue en mars, le premier ministre François Fillon avait chargé l'ASN de procéder à l'audit des installations françaises, avec pour mission de fournir des premières conclusions d'ici à la fin de l'année.

Hydrogen dissolved from water exploded at Fukushima nuclear reactor: experts

The No. 4 reactor building at the Fukushima No. 1 Nuclear Power Plant exploded four days after the March 11 Great East Japan Earthquake and ensuing tsunami, and experts believe the **explosion occurred partly because huge amounts of hydrogen were produced in the process of water being dissolved by radiation in a boiling spent nuclear fuel pool.**

A group of researchers from the University of Tokyo and the Japan Atomic Energy Agency made an analysis of the hydrogen explosion at the No. 4 reactor at the Fukushima nuclear power station. The finding will be announced at the Atomic Energy Society of Japan meeting in Kitakyushu that kicks off on Sept. 19. Radiation dissolves water into hydrogen and other elements.

When the explosion occurred, there were 1,535 fuel rods in the fuel pool of the No. 4 reactor, the largest number among the No. 1 to 4 reactors. When the Great East Japan Earthquake struck, the No. 4

reactor was suspended for regular inspections, but it lost power supply to the tsunami. The explosion occurred at the reactor on March 15, four days after the quake-triggered tsunami, because it lost cooling functions.

In reference to the No. 1 and 3 reactors where hydrogen explosions occurred, hydrogen is believed to have been produced from damaged fuel rods in the reactors. But there was no serious damage to the fuel rods in the No. 4 reactor. Tokyo Electric Power Co. (TEPCO), the operator of the crippled Fukushima nuclear complex, assumes that hydrogen entered the No. 4 reactor from the No. 3 reactor through a common exhaust pipe and exploded.

Nevertheless, the team of experts noted the fact that there was a gap of about 20 hours between the explosions at the No. 3 and 4 reactors and came to suspect that there could be other factors involved. When radiation was applied to water in flasks in three stages -- water at room temperature, at 97 degrees Celsius, and at the boiling point -- the amount of hydrogen produced at 97 degrees Celsius was 1.5 times larger than that at room temperature and 100 times that at boiling point.

Hydrogen can explode when its concentration in air surpasses 4 percent. Steam that was stuck to the upper parts of the reactor building became water again when it cooled down, but the hydrogen is believed to have remained in gas form and increased its concentration in the air.

"In addition to the hydrogen entering from the No. 3 reactor, water was probably dissolved into hydrogen by radiation. We want to verify whether it will occur in an environment in sizes equal to those of the reactor building or the spent nuclear fuel pool," said Yosuke Katsumura, professor of radiation chemistry at the University of Tokyo.

Fukushima survey sparks call for allocation of personal radiation monitoring badges

The National Cancer Center has called for radiation monitoring badges to be distributed to residents of Fukushima Prefecture following a survey on health workers that failed to find a correlation between their radiation dosages and the time they spent outside.

On Sept. 13, the center and Mutsuko Watarai, an associate professor at Tokyo Health Care University, released the results of a radiation exposure survey on health workers in areas near the crisis-hit Fukushima No. 1 Nuclear Power Plant. The workers were given radiation monitoring devices called "glass badges" to determine their radiation exposure. However, **no correlation was seen between their exposure levels and the time they spent outside**, suggesting that determining residents' radiation exposure by simply asking when and where people were at certain times would be difficult.

"It would be hard to calculate radiation dosages through a survey on people's movements alone. Each person should have their own glass badge," a National Cancer Center representative said.

The survey was conducted between May 1 and 31, with a total of 147 workers being given radiation exposure badges. Accumulated dosages for the month ranged between 0.1 and 0.3 millisieverts in the town of Kawamata, up to 0.1 millisieverts in the city of Tamura, and up to 0.7 millisieverts in Minamisoma. Exposure varied among individuals within the same municipality. In the city of Iwaki, radiation dosages ranged between 0 and 0.1 millisieverts over a two-week period.

A total of 85 of the 147 workers gave detailed accounts of the time they spent outdoors, but no proportional relationship was seen between the time they spent outside and their radiation dosages.

"Glass badges should be distributed to the people of Fukushima as soon as possible," said Takamasa Kayama, chief director of the National Cancer Center, indicating that the center would work to win understanding from the Ministry of Health, Labor and Welfare and the Fukushima Prefectural Government.

Fukushima Prefectural Government officials said the prefecture has started distributing monitoring devices to children mainly up to junior high school age and pregnant women.

Cesium in Pacific likely to flow back to Japan in 20-30 years

TOKYO (Kyodo) -- Radioactive cesium that was released into the ocean in the nuclear accident at the Fukushima Daiichi power plant is likely to flow back to Japan's coast in 20 to 30 years after circulating in the northern Pacific Ocean in a clockwise pattern, researchers said Wednesday.

Researchers at the government's Meteorological Research Institute and the Central Research Institute of Electric Power Industry disclosed the findings at a meeting of the Geochemical Society of Japan, an academic association, in Sapporo.

The researchers estimated that **the amount of radioactive cesium-137 that was directly released into the sea came to 3,500 terabecquerels over the period from March to the end of May, while estimating that roughly 10,000 terabecquerels fell into the ocean after it was released into the air.**

One terabecquerel equals 1 trillion becquerels. Cesium-137, which has a relatively long half life of about 30 years, can accumulate in the muscles once it is in the body and can cause cancer.

A total of 13,500 terabecquerels of radioactive cesium-137 is slightly more than 10 percent of that of the residual substance left in the northern Pacific after previous nuclear tests, according to the researchers.

The researchers, including chief researcher Michio Aoyama of the Japan Meteorological Agency's research institute, analyzed how the radioactive material dispersed in the sea during the latest accident, using data on radioactive materials detected after the nuclear tests.

According to the analysis, the cesium is expected to first disperse eastward into the northern Pacific from the coast of Fukushima Prefecture, northeast of Tokyo, via relatively shallow waters about 200 meters deep or less.

The cesium will then be carried southwestward from the eastern side of the International Date Line at a depth of 400 meters before some of it returns to the Japanese coast carried northward by the Japan Current from around the Philippines.

The analysis showed that some of the cesium will flow into the Indian Ocean from near the Philippines, and in another 40 years will reach the Atlantic, while some will turn westward south of the equator after reaching the eastern end of the Pacific and crossing the equator.

Tokyo Electric Power Co., the operator of the crisis-hit plant, said about 1,000 terabecquerels of radioactive cesium had leaked into the sea from cracks at the plant.

The researchers' estimate, which was calculated using the density of cesium detected in seawater, is more than triple that.

"To get a complete picture of cesium-137 released in the accident, we need highly precise measurements across the Pacific," Aoyama said before Wednesday's meeting.

(Mainichi Japan) September 14, 2011

TEPCO starts cooling No. 2 reactor in more efficient way

TOKYO (Kyodo) -- The plant operator of the crippled Fukushima Daiichi nuclear complex said Wednesday that it has started cooling the No. 2 reactor core in what is believed to be a more efficient method.

The method of showering water onto the reactor core has already been applied at the No. 3 reactor, which saw the temperature measured at the bottom of the reactor pressure vessel drop below 100 C on Sept. 5 for the first time since the nuclear crisis erupted in March, according to Tokyo Electric Power Co.

Bringing the temperature of the bottom of the vessels below around 100 C is part of the key conditions for achieving the plant's cold shutdown. The No. 1 reactor is already below 90 C.

As for the mission to reduce the amount of highly radioactive water accumulating in the plant, the utility said it has decided to rely mainly on a recently introduced device developed by Toshiba Corp. and other companies from October, rather than the installation developed by Kurion Inc. of the United States and France's Areva.

The decision to use what is named SARRY, an acronym for simplified active water retrieve and recovery system, was apparently taken because it has fewer problems.

The installation developed by Kurion and Areva will be used as a backup system for SARRY.

Ensuring stable operation of the water decontamination system is seen as key to ending the nuclear crisis as it helps to reduce the amount of polluted water created as a result of the continued injection of coolant water into the troubled Nos. 1 to 3 reactors at the six-reactor complex.

The cleaned water is recycled as a coolant for the reactors.

Obama urged Kan to work hard to enhance nuclear security

TOKYO (Kyodo) -- U.S. President Barack Obama urged former Japanese Prime Minister Naoto Kan in a letter to work hard on enhancing nuclear security, indicating U.S. frustration over the delay in Japan's actions caused by the March earthquake and tsunami, Japanese government sources said Wednesday.

The content of the letter was conveyed to the Japanese government through diplomatic channels on Aug. 22, the sources said.

Obama, who hosted the first nuclear security summit in Washington in April last year to boost international cooperation to prevent nuclear terrorism, said in the letter, "I am working hard on the tasks set at the April Summit, and I urge you to do the same."

Referring to the Nuclear Security Working Group set up by the United States and Japan, Obama said, "As two nations with an advanced nuclear infrastructure, we need to take leadership on nuclear security, especially at plutonium and highly enriched uranium processing facilities."

"We have seen many encouraging steps to improve the security of nuclear materials around the world and to strengthen our individual and collective ability to prevent nuclear smuggling," the president said.

"At the same time, we are reminded almost daily of the ongoing threat of terrorism and of the necessity to do all we can to avoid the global catastrophe of a terrorist nuclear attack," he said.

Obama said the two countries need to use the second nuclear security summit to be held in Seoul in April next year "to highlight our progress on nuclear security, and to identify new steps we can take together toward the vision of a more prosperous and peaceful world, one in which nuclear threats are diminished through cooperation and purposeful action."

He also called on Japan to make good use of the Integrated Support Center for Nuclear Non-Proliferation and Nuclear Security it established in the village of Tokai, Ibaraki Prefecture, in December.

To strengthen nonproliferation and nuclear security, the center provides training for nuclear industry personnel in emerging countries that are introducing commercial nuclear power.

Obama has sent similar letters to countries other than Japan, according to U.S. government sources.

Japan and the United States held the first meeting of the Nuclear Security Working Group in January and agreed to jointly study nuclear forensics, a sophisticated technology to analyze the composition of nuclear materials and specify their source.

The two countries also reached an accord on cooperation in establishing technologies to measure nuclear materials contained in spent nuclear fuel and boosting security during times of nuclear substance transportation.

However, Japan has been slow in implementing the agreements following the March 11 disaster, which triggered the crisis at the Fukushima Daiichi nuclear plant. Japanese government officials believe the letter demonstrates Washington's concerns over Tokyo's efforts to enhance nuclear security.

The two countries have yet to start joint research on nuclear forensics technology, and a planned experiment in Tokai to measure plutonium contained in spent nuclear fuel was changed as a facility necessary for the test was damaged by the quake.

The announcement by Tokyo Electric Power Co., the operator of the crippled Fukushima plant, that it had lost contact with 88 nuclear workers deployed to contain the crisis as of late August is also believed to have raised concerns in the United States, which is keen to prevent terrorism by those who have access to nuclear materials.

IAEA: N.Korean threat in nuke proliferation

The UN nuclear watch dog agency has condemned North Korea for posing a threat through nuclear proliferation.

The regular board meeting of the International Atomic Energy Agency in Vienna discussed a report on North Korea's nuclear development on Wednesday.

The report says Libya had procured uranium material through the so-called nuclear black market, and that the material is highly likely to have originated in North Korea. It says Libya possessed the material until the country declared that it was abandoning its nuclear ambition.

The report also says a facility in Syria, which appeared to house a reactor, is supposed to have been constructed with the aid of North Korea.

Israeli warplanes destroyed the Syrian facility in an air attack 4 years ago.

At the board meeting, Japan, the US and others expressed concern over the possibility of nuclear technology spilling from North Korea into other countries.

In a chair statement, the IAEA condemned North Korea for threatening the international nuclear non-proliferation scheme.

The UN agency is expected to adopt a resolution at its annual ministerial meeting to begin on Monday urging North Korea to renounce its nuclear development program.

nuclear | 09.09.2011 – *(One week old, but worth reading)*

Fukushima spoils world appetite for nuclear power

In the six months since the Fukushima disaster, a global survey has detected mounting opposition to nuclear energy, especially in Asia. Yet Germany remains the only country to abandon the technology to date.

<http://www.dw-world.de/dw/article/0,,15352996,00.html>

Several months after the nuclear disaster in Japan, market research company Ipsos asked citizens in 24 countries how they feel about atomic energy.

In all but three of them - India, the United States and Poland - there was consensus that the time has come for cleaner, safer sources of power.

Many of the 55 percent who expressed opposition to nuclear energy cited the reactor catastrophe in Japan as the reason why they were against nuclear power.

The most notable shift was in Asia, where several countries including South Korea, Japan and China have seen the number of anti-nuclear activists double in recent months.

Those are same countries that have major nuclear expansion plans. At the start of this year, Japan's 55 reactors covered some 29 percent of its power needs. Tokyo was planning to add another 14 plants to its network.

In South Korea, 21 reactors currently supply 35 percent of the energy, and there are another 11 plants in the pipeline.

China and India, each of which generate just 2 percent of their fuel from nuclear power, were planning 77 and 23 new reactors, respectively.

More on Deutsche Welle web site : <http://www.dw-world.de/dw/article/0,,15352996,00.html>

Up to one-seventh of Fukushima may be contaminated

TOKYO (Kyodo) -- It is likely that more than 2,000 square kilometers of land in Fukushima Prefecture have been contaminated with radioactive substances released from the Fukushima Daiichi nuclear power plant and need to be decontaminated, research indicated Thursday.

The area accounts for about one-seventh of the whole prefecture, according to the estimation by Yuichi Moriguchi, a professor at the University of Tokyo. The volume of contaminated top soil that would need to be removed totals 100 million cubic meters.

As forests account for about 70 percent of the estimated contaminated areas, leaves and branches will need to be removed, according to the study that was based on radiation distribution maps released by the government in late June.

Moriguchi said that although it is unrealistic to remove all the contaminated soil, it would be necessary to implement various decontamination methods depending on the type of land -- forests, farmland and urban areas.

His calculations indicate that contaminated areas with an estimated dose of radiation of 1 microsievert per hour or higher at a height of 0.5-1.0 meter came to 2,000 sq. km which include no-go zones near the Fukushima plant that was hit by the March 11 earthquake and tsunami.

Most of the areas are within Fukushima, while some parts of Miyagi, Ibaraki and Tochigi prefectures surrounding Fukushima are also included.

(Mainichi Japan) September 15, 2011

Sunflowers having little effect on reducing radiation; scraping soil effective

Growing sunflowers to remove radioactive cesium has turned out to have little effect, while scraping off the topsoil of contaminated farmland has been effective, the Ministry of Agriculture, Forestry and fisheries has announced.

The ministry released on Sept. 14 the results of experiments on the removal of radioactive materials from farmland it had conducted in the Fukushima Prefecture village of Iitate and other locations since May.

According to the results, radioactive cesium can be reduced by 70 to 90 percent from farmland if three to four centimeters of its topsoil was scraped off. Meanwhile, growing sunflowers with the hope that they would absorb radioactive substances turned out to have little effect.

"It is difficult to put the sunflower method into practical use at the moment," said the ministry.

The sunflowers that the ministry had planted in Iitate in May had absorbed around 52 becquerels of cesium per kilogram, according to the ministry. Even if sunflowers worth 10 kilograms were grown per square meter of farmland, only about 1/2000th of cesium in the soil could be absorbed, the ministry said.

The topsoil removal method, on the other hand, proved to be highly effective, with radioactive cesium in the soil plunging from 10,370 becquerels to 2,599 becquerels per kilogram after three to four centimeters of the topsoil was scraped off.

The method becomes even more effective when the topsoil is hardened by pharmacological agents before being removed, or when the topsoil was taken away all together with grass roots. Both methods could reduce levels of cesium by 82 to 97 percent.

However, these methods would generate 30 to 40 tons of waste soil per 100 square meters. **Since an estimated 8,300 hectares of farmland in Fukushima Prefecture is contaminated with 5,000 or more becquerels of cesium per kilogram, decontaminating those areas could result in some 3.5 million tons of waste soil, according to the ministry.**

(Mainichi Japan) September 15, 2011

UN: Fukushima plant based on poor safety assessment

UN Secretary General Ban Ki-moon has blamed the nuclear accident at the Fukushima Daiichi power plant in northern Japan on its design which, he says, was based on poor hazard assessments of natural disasters.

The secretary general released a 43-page report on Wednesday, after studying the March accident with UN entities including the International Atomic Energy Agency and the World Health Organization.

The report says it is necessary for nuclear power stations to strengthen their safety standards.

It proposes the creation of a global system to allow the IAEA to internationally monitor radiation levels, citing the international impact of major nuclear accidents and emergencies.

The report calls for an international emergency response framework in the event of nuclear accidents, to secure human health and food safety.

The report also stresses the importance of the peaceful use of nuclear energy, in order to help improve the lives of the 2.4 billion people in developing countries suffering from energy poverty.

The UN secretary general is to convene a high-level meeting on nuclear safety and security on September 22nd in New York.

Areva suspend la production de deux usines d'uranium à cause du Japon

LEMONDE.FR avec AFP | 15.09.11 | 17h54 • Mis à jour le 15.09.11 | 20h35

Areva a suspendu pour deux mois la production de deux usines françaises de transformation d'uranium, la Comurhex, à Malvesi, dans l'Aude, et le Tricastin, dans la Drôme.

La raison invoquée par le groupe nucléaire est la baisse de la demande des centrales nucléaires au Japon après la catastrophe de Fukushima. *"Cette décision se justifie par les événements intervenus au Japon qui amènent aujourd'hui à une baisse des livraisons des électriciens japonais et à une pression sur les prix à court terme de ce marché"*, explique Areva, jeudi 15 septembre.

La Comurhex, filiale à 100 % d'Areva, transforme l'uranium naturel en deux phases pour obtenir de l'hexafluorure d'uranium, qui est ensuite enrichi et transformé en combustible pour les centrales nucléaires.

Aucune mesure de chômage technique n'est prévue, du fait de congés et de formations prévues pour les employés, selon Areva.

AREVA VA TERMINER LA CENTRALE DE BELLEFONTE

Le groupe nucléaire a par ailleurs annoncé aux [Echos](#) (article payant), jeudi, qu'il avait été choisi pour terminer la construction de la centrale nucléaire américaine de Bellefonte (Alabama), dont les travaux avaient été interrompus en 1988.

Areva n'a pas voulu communiquer d'éléments financiers sur ce contrat, que le président du directoire, Luc Oursel, dit devoir signer jeudi.

La France saurait-elle faire face à une catastrophe nucléaire ?

LEMONDE.FR | 15.09.11 | 18h36

Même s'il a rapidement été maîtrisé, [l'accident](#) de la centrale de Marcoule n'a pas manqué de rouvrir le [débat](#) sur la gestion d'un accident nucléaire grave en France. Cette fois, les conséquences sont restées confinées au périmètre le plus réduit : celui de ce centre de traitement de déchets nucléaires du Gard où l'explosion d'un four a fait un mort et quatre blessés.

Mais que se serait-il passé si l'accident de Marcoule avait entraîné des fuites de particules radioactives, portées vers Avignon, à une trentaine de kilomètres, par le mistral qui soufflait ce jour-là ? Plus généralement, maintenant que le drame de Fukushima a laissé entendre que l'impensable était possible, la question se pose : comment une telle catastrophe nucléaire serait-elle gérée en France ?

Selon Jean-Luc Godet, à la tête de la Direction des rayonnements ionisants et de la santé à l'Autorité de sûreté nucléaire (ASN), *"l'accident de Tchernobyl a montré les limites d'une mentalité probabiliste"*, qui suppose que les probabilités statistiques d'un accident sont si faibles que nul n'ait besoin de s'en préoccuper.

DANS L'URGENCE

La catastrophe dans la centrale ukrainienne conduit donc les autorités à se pencher enfin sur une doctrine française à suivre en cas d'accident... trente ans après la construction du premier réacteur produisant de l'électricité nucléaire en France, à Marcoule justement. Les Plans particuliers d'intervention (PPI) font alors leur apparition, supervisés, autour de chaque site nucléaire, par les préfets, et encadrés désormais par [un décret de 2005](#). Le principe : prévoir un confinement de la population, une éventuelle évacuation, et la prise de comprimés d'iode.

Ces PPI forment une base indispensable à l'intervention en phase d'urgence, mais encore limitée. [Au Japon](#), des villages ont été évacués dans un rayon de cinquante kilomètres autour de la centrale de Fukushima. En France, ces plans couvrent une zone ne dépassant pas dix kilomètres, voire 500 mètres pour certaines installations, déplore Roland Desbordes, président de la Criirad (Commission de recherche et d'information indépendante sur la radioactivité). Au-delà, rien n'est prévu pour les populations.

Ce n'est pas la seule limite. A Marcoule par exemple, [la zone couverte par le PPI](#) est répartie entre le préfet du Gard et celui du Vaucluse, avec les risques que cela soulève en termes d'ordres contradictoires.

DES PLANS OPÉRATIONNELS ?

Mais surtout, des doutes existent sur l'application des PPI et leur capacité à parer à toute éventualité. Concernant la première mesure, le confinement : *"Lors de l'accident d'AZF à Toulouse, le préfet a ordonné de s'enfermer chez soi. Mais dans certaines maisons, les fenêtres avaient éclaté. Et dans les zones rurales, si on coupe la ventilation d'un élevage en batterie, tous les animaux meurent"*, explique Raymond Sené, physicien nucléaire membre du GSIEN (Groupement des scientifiques pour l'information sur l'énergie nucléaire).

Les PPI prévoient également la mise à disposition de comprimés d'iode – qui permettent uniquement de [se protéger d'une contamination à l'iode radioactive](#), à l'origine de cancers de la thyroïde. Mais l'épisode de Marcoule a démontré les dysfonctionnements du dispositif : *"c'est un fiasco"*, affirme Alexandre Pissas, président de la CLI (Comité local d'information) de ce site. *"Toutes les communes concernées n'ont pas été chercher leurs boîtes, certains habitants non plus, et des stocks entiers d'iode sont périmés dans les pharmacies..."* De plus, selon Roland Desbordes, *"il est désormais interdit de se procurer de l'iode au-delà de la zone très limitée du PPI."*

Reste la question sensible de l'évacuation. Dans les PPI, un accident aussi important que celui de Fukushima n'est clairement pas envisagé. Car de [nombreuses centrales](#) sont installées à proximité de grands foyers de population – la centrale de Bugey est à 35 kilomètres de Lyon, celle de Nogent-sur-Seine à une centaine de kilomètres de la région parisienne... Pour Yves Cochet, député EELV (Europe Ecologie-Les Verts), *"s'il y a un accident grave dans la centrale de Nogent, que les vents soufflent vers l'Ouest, que les nappes phréatiques et la Seine sont contaminées, ce sont potentiellement 12 millions de Franciliens qui sont touchés. Or, rien n'est prévu pour faire face à cette éventualité, et de toute façon, il est totalement impossible d'évacuer rapidement Paris et sa banlieue."*

PLAN "PLUTÔT CONFIDENTIEL"

Selon Yves Cochet, après la phase d'urgence, l'armée a toutefois élaboré un plan *"plutôt confidentiel"*, où il est notamment prévu, si aucune évacuation rapide n'est possible, *"de départager la population déjà trop contaminée pour être évacuée, et celle qui pourra partir. Une discrimination assez effrayante..."* En tout cas, au-delà des premiers jours, aucun *"document officiel"* ne prévoit pour le moment la marche à suivre, assure Jean-Luc Godet.

Une enveloppe financière est par contre prévue pour faire face aux dommages nucléaires, à hauteur de 1,5 milliard d'euros, dont près de la moitié avancée par l'exploitant. Le montant est insuffisant, estime le président de la Criirad : *"Il n'y a pas d'assurance pour le nucléaire. Et l'argent mis sur la table équivaut seulement au prix du sarcophage posé autour de la centrale de Tchernobyl."*

"PENSER LA SUITE"

Pour faire face à ces lacunes, l'ASN est chargée, depuis 2005, de penser le moyen et le long terme. *"A l'époque, on faisait des exercices où le préfet ordonnait la mise à l'abri des gens, puis c'était tout, il ne savait pas comment lever cet ordre... Il fallait logiquement penser la suite"*, explique Jean-Luc Godet.

Depuis six ans, le [Codirpa](#) (Comité directeur pour la gestion de la phase post-accidentelle) mobilise donc environ 130 membres – associations, élus, CLI, agences sanitaires, experts européens en radioprotection, exploitants nucléaires, etc. – pour plancher sur ce problème complexe. Avec un tas de questions sensibles : comment nettoyer les maisons dans les zones urbaines contaminées ? Que faire des objets et déchets radioactifs ? Comment enfouir ou déplacer les sols superficiels contaminés ? Comment réhabiliter les terres devenues improductives pour l'agriculture ?

Une des premières avancées du Codirpa est de dessiner un zonage du territoire en cas d'accident : une première zone dite "d'éloignement" de quelques kilomètres ; une deuxième zone de "protection" où *"il est plus avantageux de rester que de partir"*, selon M. Godet, et où la population vivrait dans des habitations nettoyées sans pouvoir consommer les produits de la terre ; puis une zone de "surveillance", sur une soixantaine de kilomètres à la ronde, où les produits alimentaires sont susceptibles de dépasser les niveaux maximum admissibles de radioactivité.

RIEN DE PRÉVU EN CAS D'ACCIDENT GRAVE

Mais pour l'instant, le Codirpa ne réfléchit pas encore à un scénario à la hauteur de Tchernobyl ou de Fukushima. Il se fonde sur les simulations de deux accidents, dont le plus grave occasionnerait des rejets radiocatifs pendant seulement vingt-quatre heures, alors qu'à Fukushima, six mois après la catastrophe, les fuites n'ont pas pu être maîtrisées !

L'examen d'un accident plus grave et complexe viendra dans un second temps, après la publication d'une première doctrine sur la gestion d'un accident modéré début 2012 et après avoir tiré les leçons de Fukushima, promet Jean-Luc Godet.

Autre faiblesse du Codirpa : malgré un effort de concertation avec les associations et les acteurs locaux, plusieurs voix se sont élevées contre une **implication et un pouvoir encore insuffisants de la population**. La Criirad, elle, a refusé de participer au comité de l'ASN. Notamment parce que le Codirpa accorderait *"une place maîtresse à une association comme le CEPN [Centre d'étude sur l'évaluation de la protection dans le domaine nucléaire], composée d'Areva, d'EDF, du CEA et de l'IRSN, représentant en fait le lobby nucléaire"*. Plus grave, selon Roland Desbordes : *"Sur le fond, le Codirpa construit son travail sur des programmes de recherche européens sur Tchernobyl – Ethos et Core – qui ont conclu, en gros, que la vie pouvait très bien s'organiser dans des zones contaminées, en minorant largement les problèmes de la radioactivité et de l'état de santé de la population. Il veut adapter ce modèle en France"*.

Angela Bolis

Edano says Fukushima Daiichi nuclear power plant's resumption difficult

TOKYO (Kyodo) -- Japan's new industry minister Yukio Edano said Thursday it will be difficult to restart the Fukushima Daiichi nuclear power plant, in addition to the Nos. 5 and 6 reactors of the crippled Fukushima Daiichi plant, as **local residents are unlikely to approve the resumption**.

In an interview with Kyodo News and other media organizations, Edano said that winning approval of local municipalities where idled reactors are located is a "precondition" for their reactivation.

Tokyo Electric Power Co., which operates the two nuclear power complexes in Fukushima Prefecture, plans to scrap the troubled Nos. 1-4 reactors of the six-reactor Fukushima Daiichi plant, and Edano had earlier said when he was chief Cabinet secretary in the wake of the start of the Fukushima nuclear crisis that the remaining Nos. 5 and 6 reactors will likely be decommissioned, too.

Asked if he still believes so, Edano said, "I do not believe that we can obtain local approval" in both cases.

The Nos. 5 and 6 units at the Fukushima Daiichi plant and all four reactors at the Fukushima Daini plant, which is located about 15 kilometers south of the crippled plant, achieved a stable condition called cold shutdown in the early days of the crisis.

Edano said the government will try to disclose lessons learned from the Fukushima nuclear crisis, including the cause of the nuclear accident, in a more appropriate manner, as he believes distrust among the public about government information disclosure is among the reasons municipalities hosting idled reactors are reluctant to allow them to resume operating.

A number of reactors in Japan remain shutdown for regular checkups amid heightened public concern over nuclear power following the nuclear accident at the Fukushima Daiichi plant, triggered by the March earthquake and tsunami, and the reactors need to pass the so-called nuclear "stress tests" before resuming operations.

If the resumption of their operation is not allowed, all of Japan's 54 reactors will be out of operation by May.

Regarding electricity supply, Edano said the government intends to avoid ordering restrictions this winter on electricity use.

"I believe there is a plenty of room that we can live through this situation without issuing a power-saving order, if we combine (power-saving) efforts," Edano said.

On trade issues, Edano suggested that Japan could decide to participate in the U.S.-led Trans-Pacific Partnership free trade negotiations if a consensus that the trade accord would not devastate the agriculture and other sectors in Japan is reached.

"If agriculture and other policies are solidly promoted, I believe there are a plenty of chances that we reach a positive decision about the TPP," he said.

The Japanese government postponed its earlier plan to decide by June on whether to join the negotiations for the major Pacific free trade accord as the March disaster prompted the government to review its policy priorities.

As for Japan Business Federation head Hiromasa Yonekura's recent remarks that he hopes Edano will "study various economic mechanisms more," the new economy minister expressed a sense of discomfort, saying that it was a way of saying Yonekura looked down on him.

Yonekura has been critical of Edano's earlier remarks that debt waivers by Tokyo Electric's lender banks would be necessary because of the massive compensation the utility bears due to the nuclear accident.

Edano became the minister of economy, trade and industry Monday after his predecessor Yoshio Hachiro resigned after making remarks deemed insensitive to those affected by the Fukushima nuclear crisis.

Institute probing radioactive contamination of Fukushima forests

FUKUSHIMA, Japan (Kyodo) -- The Forestry and Forest Products Research Institute in Tsukuba, Ibaraki Prefecture, is investigating the extent of radioactive contamination of wooded areas in Fukushima Prefecture, where the crippled Fukushima Daiichi Nuclear Power Station is located.

The government, which has concentrated so far on how to decontaminate residential areas, has yet to start to remove radioactive substances from the forests, which cover 70 percent of the prefecture.

Shinji Kaneko, director of the institute's Forestry Site Environment, said, "It is crucial for us to make clear the state of contamination (of forests) in considering how to decontaminate (the woodland) effectively."

In October, the institute plans to release the results of its analysis of samples of cedar trees, taken from the villages of Kawauchi and Otama and the town of Tadami.

The findings are likely to help the government devise decontamination methods for the forests, now that it is set to rescind restrictions on movements of residents in areas within 20-30 kilometers from the crippled plant.

In August, the government acknowledged difficulties involved in removing soil and ground cover from the forests, saying, "Huge volumes of soil and other (contaminated) items would be involved as the forests occupy a huge area."

The government effectively shelved any approach to decontaminating the forests when it said a removal of both contaminated soil and compost materials would strip the forests of their functions such as water retention.

Excessive cesium found in burned industrial waste in 3 prefs.

TOKYO (Kyodo) -- Radioactive cesium in excess of the benchmark of 8,000 becquerels per kilogram was discovered in ashes and dust from industrial waste incinerators in six locations in Iwate, Fukushima and Chiba prefectures, the Environment Ministry said Thursday.

Among 110 industrial waste disposal facilities covered as samples in 16 prefectures in eastern and northeastern Japan, the cesium reading stood at 10,800 to 144,200 becquerels at four in Fukushima, 23,000 becquerels at one in Iwate and 11,500 becquerels at one in Chiba, it said.

A similar study found in late August that ashes from nonindustrial incinerators were polluted with over 8,000 becquerels of cesium per kg in Tokyo and six prefectures. A worker exposed daily to 8,000 becquerels of cesium would still not exceed the annual radiation exposure limit of 1 millisievert.

At the end of August, the ministry decided to get local authorities to solidify with cement incinerated dust and ashes containing 8,000 to 100,000 becquerels of cesium per kg and cover them with watertight sheeting before they are buried in the ground.

As for those with more than 100,000 becquerels, the ministry made it possible to bury them after the level of cesium falls below the mark by solidifying them with cement. It earlier decided to allow those containing up to 8,000 becquerels to be buried in waste disposal sites only if residential houses are not built there in the future.

(Mainichi Japan) September 16, 2011

Japan nuclear agency chief regrets lenient crisis management approach

TOKYO (Kyodo) -- Japan's nuclear safety agency chief has voiced regret that its crisis management approach was too lenient in light of the Fukushima Daiichi nuclear plant accident.

"Our approach on crisis management had been lenient," Nuclear and Industrial Safety Agency Director General Hiroyuki Fukano said in a recent interview with Kyodo News, after his predecessor who was dismissed in August over his handling of the meltdown accident.

When the March 11 earthquake and tsunami hit northeastern Japan, the plant lost electricity sources due primarily to the large tsunami, leading to meltdowns of three reactor cores, explosions at three reactor buildings and widespread radioactive contamination.

"We should have taken a realistic approach to the possibility that all electricity sources could be lost for real," Fukano said.

"If we had taken a realistic approach, we could have made a difference in training, human resources development and the plant operator's preparedness," he said.

Fukano also said the government's disaster preparations "had been insufficient in many ways." "As we had taken much time to assess quake resistance, we had lagged in taking anti-tsunami measures," he said.

He indicated that the presence of as many as six reactors at the plant made it difficult to effectively address the accident in which all six suffered damage. "It was very difficult to secure sufficient human resources and equipment such as power-supply vehicles," he said

The government plans to create a new nuclear safety agency under the Ministry of Environment next April to take over the nuclear regulatory operations of Fukano's agency under the Ministry of Economy, Trade and Industry and other government bodies.

"A major challenge for the new agency would be to develop human resources with 'frontline' expertise such as knowledge about the real operations of a nuclear plant," he said. "We will provide anything as required to allow the new body to become a firm regulatory organization and avoid any similar failures."

(Mainichi Japan) September 16, 2011

Cesium found in industrial waste

Industrial waste at 6 incineration facilities has been found to contain radioactive cesium at levels that exceed the government-set limit for disposal.

Following the nuclear accident in Fukushima, the ashes of garbage from private homes were found to contain levels of radioactive cesium, well above the limit of 8,000 becquerels per kilogram. The contaminated garbage was treated at waste disposal plants in the Kanto and Tohoku regions.

The Environment Ministry had asked 16 prefectures in the Tohoku, Kanto and Koshin-etsu regions to examine ashes from woodchips and other industrial waste.

Out of the 110 incineration facilities tested, levels of radioactive cesium exceeded 8,000 becquerels per kilogram at 4 sites in Fukushima Prefecture and one each in Iwate and Chiba prefectures. The highest measurement was 144,420 becquerels per kilogram at one facility in Fukushima.

These facilities were found to be temporarily keeping the ashes without disposing of them in landfill sites.

Since the 6 facilities had been storing the waste material outdoors before incineration, the Environment Ministry plans to examine other facilities that follow similar methods.

Researchers say meltdown could have been avoided

A group of researchers says the meltdown of a reactor at the Fukushima Daiichi nuclear power plant could have been avoided **if water injection had been carried out 4 hours earlier than it was.**

The researchers at the Japan Atomic Energy Agency on Thursday reported the finding based on a computer simulation of the accident at the plant's No. 2 reactor.

The core meltdown took place within a few days after the reactor's cooling system failed due to the major earthquake and tsunami on March 11th.

The Tokyo Electric Power Company, or TEPCO, said earlier that data analysis shows that the cooling system may have stopped working shortly after 1 PM on March 14th.

The utility started injecting water to cool the reactor at around 8 PM that day, after reducing pressure in the facility. But by 8 PM the next day -- around 100 hours after the quake -- much of the reactor's fuel had melted and collected at the bottom of the reactor's pressure vessel.

The simulation suggests that if water had been injected by around 4 PM, it could have prevented the meltdown by lowering the temperature of the fuel before it reached 1,200 degrees Celsius, destroying the fuel's container.

Group leader Masashi Hirano says the damage to the fuel could have been avoided, and that **he wonders why TEPCO did not start injecting water earlier despite difficulties.**

TEPCO says it doesn't believe the operation was delayed, adding that workers did their best amid high radiation levels and other severe conditions.

Of the plant's 6 reactors, the No. 1 to No. 3 suffered meltdowns after losing cooling functions.

At the No. 2 reactor, a hydrogen explosion on March 15th caused the release and spread of massive amounts of radioactive substances.

Thursday, September 15, 2011 21:46 +0900 (JST)

Infants to be tested for radiation exposure

Minamisoma City in Fukushima Prefecture has decided to include infants and small children in tests for radiation taken into their bodies.

Parts of the city are designated as evacuation zones following the accident at the Fukushima Daiichi nuclear plant.

Since July, the city has been testing residents for internal radiation exposure, but infants and small children were excluded as the equipment did not fit them. It has been studying other test methods for them.

A city-run general hospital, working with a Tokyo-based medical firm, has decided on a method to measure amounts of radioactive substances in urine and began accepting applications on Thursday.

The new test will be provided free of charge for children 6 years old and under. Results will be mailed about 2 weeks after urine samples are received.

A mother said she has not been allowed to go outside with her baby, adding she wants to have her baby tested as soon as possible.

An official at the hospital said many parents must be worried about the health of their children, and that he hopes the tests would ease their concerns.

17 Tons of U.S.-Supplied Weapons-Grade Nuclear Material Missing

Thursday, September 15, 2011 -

http://www.allgov.com/US_and_the_World/ViewNews/17_Tons_of_US_Supplied_Weapons_Grade_Nuclear_Material_Missing_110915

The United States has lost sight of enough nuclear material, which was provided to friendly countries for civilian energy use, to manufacture hundreds of nuclear warheads.

An [investigation](#) by the [Government Accountability Office](#) found that the [U.S. Department of Energy](#) and the [Nuclear Regulatory Commission](#) could not completely account for about 17 tons of weapons-grade uranium and plutonium that was shipped to 27 nations over the past few decades. The agencies also were faulted for not having a sound policy for tracking down the materials.

America's accounting for the exported nuclear material is so bad that the [International Atomic Energy Agency](#) may rule that the U.S. is in violation of its international anti-proliferation treaty obligations.

Although the U.S. has given more than two dozen countries nuclear fuel, reactors and reactor components for non-military purposes, it only conducts annual inventories with five of the nations. But because the location of this material is not properly monitored, it could be used to develop weapons of mass destruction, if it fell into the wrong hands.

-Noel Brinkerhoff

Radiation fears, shipment bans, weigh heavily on mushroom pickers, growers

A poster seen on Sept. 16 in Tanagura, Fukushima Prefecture, urges potential mushroom hunters not to pick mushrooms or ship them due to radiation concerns. (Mainichi)

The ban on wild mushroom shipments from 43 Fukushima Prefecture municipalities announced on Sept. 15, paired with widespread radiation fears, is discouraging pickers from their usual mushroom-hunting trips into the woods.

The ban came after wild mushrooms containing cesium beyond the legal limit of 500 becquerels per kilogram were found in the prefecture. Tawny milkcap mushrooms containing cesium over the legal limit, meanwhile, have also been found in Takahagi, Ibaraki Prefecture, endangering mushroom-picking in that region as well.

In the town of Tanagura in Fukushima, tawny milkcap mushrooms picked this month were found to contain 28,000 becquerels of cesium, or 56 times the legal limit. The town is famous for matsutake mushroom hunting between the end of September and late October each year.

The town holds an annual mushroom festival in October, and the festival is a big draw for the matsutake mushrooms in Japanese sake on offer, as well as a bingo game offering expensive locally harvested matsutake as a major prize. The events were canceled this year amid radiation concerns, leading an official of the town's tourism association to say, "We wonder if we can hold such events next year."

Tanagura is about 70 kilometers from the crippled Fukushima No. 1 nuclear power station, and it has atmospheric radiation of about 0.2 to 0.3 microsieverts per hour.

The Japanese Society of Soil Science and Plant Nutrition says wild mushrooms are more likely to absorb radioactive materials than other food products. Some studies indicate that mushrooms such as matsutake and tawny milkcap mushrooms, both of which grow out of the ground, tend to register higher levels of radiation than mushrooms which grow on dry vegetation, like maitake and nameko.

The impact of radiation fears is not limited to Fukushima and Ibaraki prefectures, however.

The Jindaira Farm in Nakanojo, Gunma Prefecture, also organizes a mushroom hunting tour every autumn, but the number of participants -- mainly from Tokyo, Saitama and other neighboring prefectures -- is down by half this year. Its 76-year-old owner said, "The mushroom season is going to start soon, but I am worried the effects (of the radiation fears) are going to get worse."

The Mikawa Kanko mushroom park in Aga, Niigata Prefecture, says it has received inquiries from potential visitors about radiation but told them its mushrooms are safe because it grows them indoors.

Amid the radiation furor and news of shipment bans, major mushroom growers are taking measures to defend themselves.

Yukiguni Maitake Co. in Minamiuonuma, Niigata Prefecture, bought testing devices at a price of 15 million yen each, and on Sept. 15 started testing mushrooms for radiation. The firm is posting serial numbers of its mushroom products on its website to allow customers to check the safety of their purchases.

"No radioactive materials have been detected so far, but we want to assure our customers of the safety of our products," a Yukiguni Maitake representative said.

Unlike other farm products, wild mushrooms are picked by mushroom hunters who then bring them to retailers, direct sales stores, and local roadside markets.

The Forestry Agency is advising those planning to go mushrooming to check the websites of respective local governments for the results of radiation tests and gather other pertinent information.

(Mainichi Japan) September 16, 2011

Most core detectors found damaged at Fukushima No. 1 reactor

TOKYO (Kyodo) -- Tokyo Electric Power Co. said Friday most of the detectors lying below the pressure vessel at the No. 1 reactor of the crippled Fukushima Daiichi nuclear power plant that check the condition of the control rods have been found damaged.

The damage -- mostly burnt wiring or electrical shortages -- is believed to have been caused by the intense heat in the wake of a core meltdown.

The utility conducted current tests on the detectors, which each cover 97 control rods, and found only one detector functioned normally, it said.

Junichi Matsumoto, a senior official at the utility, said he believes the detectors suffered such damage as both pressure and temperatures exceeded the given design limits for the pressure vessel.

Head of nuclear watchdog criticizes TEPCO over blacked-out documents

The largely blacked-out emergency operation manual submitted by TEPCO to a special Diet committee is seen in this Sept. 7 photo. (Mainichi)

The head of a government nuclear watchdog has criticized Tokyo Electric Power Co. (TEPCO) for not being transparent enough, after it submitted documents earlier this month that were mostly blacked out.

"Why don't they release all the information? **There are problems with TEPCO's attitude toward providing information,**" Hiroyuki Fukano, 54, head of the Nuclear and Industrial Safety Agency (NISA), told the Mainichi in an interview on Sept. 16.

The documents in question include an operation manual for responding to nuclear accidents.

"NISA has still not received the manual (in full)," Fukano said. "It is our job to investigate problems such as why the emergency condenser (for cooling the No. 1 reactor at the Fukushima No. 1 Nuclear Power Plant) didn't work properly, and the operation manual serves as a base for such investigations." Fukano indicated that NISA will request non-blackened out documents from TEPCO.

Regarding the current state of the Fukushima No. 1 nuclear plant six months on from the start of the crisis, Fukano said, "Although conditions have stabilized, there are still large amounts of radioactive water at the site, and we can't say the situation is under control. There are still many problems to tackle."

On the plant's complete loss of electricity after the earthquake, Fukano said, "Such a possibility hadn't seemed real to us. There was a feeling that a complete loss of power was rare, and a disaster situation would end before it got too serious."

Regarding the threat of tsunamis, he said, "We considered them as only an 'accompanying phenomenon' to earthquakes, and did not do enough (to make sure plants were prepared.)"

Commenting on criticism that NISA suffered for initially giving the Fukushima disaster a "Level 4" rating on the International Nuclear Event Scale, Fukano said, "We should have given (an accurate) rating sooner. That's something that we are rightly criticized over."

On the safety of other nuclear plants around the country, Fukano said, "I cannot say that they are absolutely safe, and I won't. Nothing involving humans is 100 percent safe. However, in stress tests from here on, we will announce what risks the plants face and how prepared they are for disasters."

Fukano, who worked under the Ministry of Economy, Trade and Industry at the time of the March 11 disaster, joined NISA in late March. In August, he replaced Nobuaki Terasaka as head of NISA.

Vendredi 16 septembre 2011

Un barrage sur la faille de Fukushima

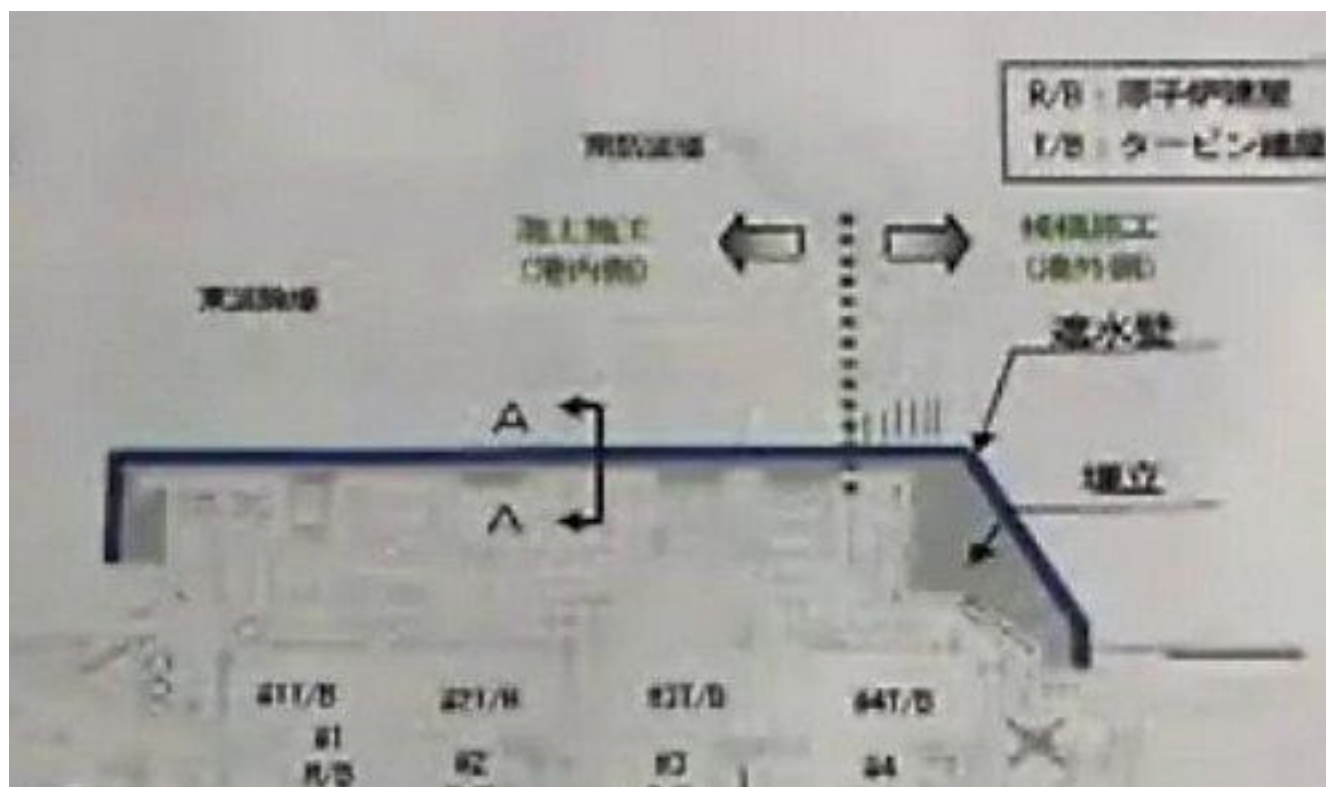

Un des grands axes de la feuille de route de Tokyo Electric Power Company pour contenir l'accident nucléaire est la prévention de la contamination de l'eau de mer. Pour cela, l'exploitant de la centrale nucléaire de Fukushima Daiichi prévoit de construire un mur en acier pour empêcher l'eau radioactive de s'écouler dans l'océan.

Actuellement, selon la firme nipponne, plus de 110 000 tonnes d'eau hautement radioactive sont actuellement stockées dans les caves des bâtiments de la centrale. L'entreprise compte utiliser entre 600 et 700 palplanches en acier pour créer un mur de 800 mètres longeant la côte. Chaque élément, de 22 mètres de long et un mètre de large, sera enfoncé profondément dans le sol sous le niveau du fond de la mer pour arrêter l'écoulement des eaux souterraines.

Cet ouvrage, prévu pour une durée de 30 ans, sera complété par un système de captage des eaux contaminées, à l'intérieur d'une importante chape de béton qui sera coulée dans l'espace entre la digue existante et la barrière en acier. Tepco estime qu'il faudra se préparer à une hausse des niveaux d'eau souterraine autour de l'usine quand le mur aura été construit. Une surveillance étroite des niveaux, le pompage des eaux souterraines et leur décontamination seront ainsi nécessaires afin d'éviter tout débordement vers l'océan.

Tepco reconnaît donc implicitement que l'eau contaminée des sous-sols est actuellement en train de s'écouler dans la mer, ce qui est en concordance avec les conclusions de [l'analyse géologique du terrain](#) : les couches aquifères en correspondance avec le plateau d'Abukuma ont un pendage dirigé vers la mer. Même si la vitesse de déplacement des eaux souterraines est lente – de l'ordre de quelques mètres par semaine – il faut être conscient que de l'eau radioactive va continuer à se

déverser régulièrement dans la mer durant au moins deux ans, date à laquelle la construction du barrage est sensée être terminée.

Plan de situation du barrage

Selon un schéma représentant la future construction en plan et en coupe, ce barrage sera établi dans le bassin de décharge des eaux de refroidissement de la centrale et au-delà, au nord et au sud, jusqu'aux quais longeant la centrale.

D'après la coupe fournie par Tepco, le barrage traversera 3 couches géologiques et le début d'une quatrième. Celles-ci font partie de la couche géologique de Tomioka, datant du Miocène Supérieur. Nous avons donc ici la confirmation que des couches aquifères se situent juste sous la centrale.

Coupe du barrage

Toutefois, même si l'effort de l'entreprise semble louable, il restera un coup d'épée dans l'eau, et ce pour plusieurs raisons :

- La première est que l'ensemble des couches sédimentaires sur lesquelles a été construite la centrale a une profondeur d'au moins 1000 mètres. Les tremblements de terre réguliers de la région font qu'il est illusoire de compter sur l'imperméabilité de ces roches. En effet, même si un grès fortement argileux a une porosité médiocre, sa friabilité le rend perméable. On peut se demander pourquoi Tepco a choisi une profondeur de 22 mètres. Peut-être tout simplement à cause d'une limite technique. C'est peut-être un indice aussi sur la localisation éventuelle des [coriums](#) ? En tout état de cause, la profondeur de ce barrage ne garantira en rien le confinement de l'eau contaminée car son passage dans les couches inférieures, même ralenti, sera toujours possible par les fissures intrinsèques à ce genre de terrain.

- La deuxième est que ce barrage va être construit sur une faille. Tepco évite de communiquer sur le sujet mais il est clair que le terrain ne se prête à aucune construction, que ce soit un réacteur ou un barrage. Cette faille est clairement visible sur un [document](#) de la NSC (autorité de sûreté nucléaire du Japon), et il est vraisemblable que durant le tremblement de terre du 11 mars, celle-ci soit redevenue

active, vus les dégâts causés aux dalles en béton en bordure de mer. Etant donné l'existence de cette faille à 200 mètres sous le niveau du sol, il est probable que la future construction ne sera pas épargnée par les mouvements de terrain causés par celle-ci. D'où de légitimes doutes sur la pérennité de l'étanchéité de la structure

Faïlle de Fukushima

- La troisième est que le barrage n'est pas fermé. Si l'eau ne peut pas passer directement vers la mer, elle va simplement contourner la barrière, en passant au nord ou au sud.

Ce barrage est donc seulement un nouvel élément dans la communication de Tepco : l'entreprise fait tout pour paraître maîtriser la situation. Elle décontamine l'eau de refroidissement des réacteurs et des piscines, elle crée de nouvelles enceintes autour des réacteurs détruits pour éviter la propagation de la radioactivité aérienne, et enfin elle construit un barrage pour épargner la mer.

Mais malheureusement l'avenir dira que tout ceci est vain : le plus gros de la contamination aérienne a été répandu sur le Japon en mars. Trop tard pour revenir en arrière. Les [coriums](#) sont sans doute quelque part dans le sous-sol. Trop tard pour les retenir. La nappe phréatique est contaminée. Trop tard pour la préserver. Le barrage souterrain est ouvert et ne sera jamais assez profond. Trop tard,

l'océan pacifique va connaître une source de pollution radioactive continue qui va contaminer l'ensemble des mers de la planète durant des dizaines d'années...

Local governments in Fukushima experiment with radiation-removing techniques

Workers experiment with draining radioactively contaminated mud from a paddy field, left, onto a tarp-covered adjacent field in Iitate, Fukushima Prefecture, on Aug. 24. (Mainichi)

Local governments in Fukushima Prefecture are experimenting with efforts to remove radioactive material spread from the crippled nuclear power plant following a request by the national government.

In August, the national government asked that local governments handle decontamination work in areas with under 20 millisieverts of radiation per year.

At a farm house in the Onami district of the city of Fukushima with mountains behind it and rice paddy fields surrounding it, the Fukushima Prefectural Government experimented with decontamination techniques in late August.

Seven painters used to working at heights participated in the experiment. Wearing helmets, boots and rubber gloves and tied with safety ropes, they used high-pressure hoses to spray the entire roof with water. At one point, one of the painters slipped and lost his balance.

"This is **too dangerous for regular people to do**," muttered Hisashi Katayose, chief of the prefecture's nuclear energy safety department, as he watched on.

Workers focused their cleaning efforts on the roof, walls, and rain gutters of the house. They hoped doing so would also reduce radiation levels in the bedroom on the second floor and the living room on the first floor.

After working for around three hours, the greatest drop in radiation levels was measured in the rain gutter on the side of the house facing the mountains. The levels had fallen from 14.5 microsieverts per hour to 1.8 microsieverts per hour. However, the second-floor bedroom's radiation level barely changed, falling from 0.7 microsieverts per hour to 0.61 microsieverts per hour.

Katayose was disappointed with the results. The area where he had most wanted to see dropped radiation levels -- the bedroom, since that is where much of a resident's time would be spent -- did not show the results he had anticipated.

Those conducting the experiments judged that radiation from the mountain slopes at the back, the garden by the house or other areas that weren't decontaminated were continuing to affect the readings. Additional efforts, using different techniques and targeting different locations, would be needed to lower the indoor levels.

"Decontamination work requires incredible money and patience," says Katayose. "The national government and Tokyo Electric Power Company should take responsibility for it, rather than leaving it to local governments."

Giving the Fukushima Prefectural Government advice on decontamination work is Hiroshi Kurigami of the Japan Atomic Energy Agency (JAEA). "They should approach it in the same way as cleaning a house," he says. According to Kurigami, in addition to wearing masks and gloves to reduce radiation exposure, those doing decontamination work should work from top to bottom, the same way that those dusting a room should.

He says that in decontaminating a house, one should first remove the leaves from trees around the house. Next, one should remove the topsoil and fallen leaves from around the home. After that, one should remove the bushes and other small plants, especially those under the eaves of the house. The drain by the road should be emptied of dirt before it is washed. For cleaning surfaces, a high-pressure hose is useful, but a scrubbing brush can be more effective in removing material.

"If levels haven't fallen even after repeated decontamination, one should consult an expert," Kurigami says.

Fukushima Prefecture is sending experts on request from neighborhood associations to help with decontamination efforts. Furthermore, the Japanese Society of Radiation Safety Management (JRSM) is offering detailed decontamination advice and consultations with experts through their website.

Additionally, the National Institute for Rural Engineering has been working to drain mud containing radioactive cesium from rice paddy fields in the village of Iitate, Fukushima Prefecture. The JAEA has developed a technique to decontaminate pools using the mineral zeolite, which can absorb radioactive cesium, and is using the technique in Fukushima Prefecture.

Another issue is what to do with contaminated soil and other remains of decontamination work. According to the JRSM, they were able to reduce the radiation coming from contaminated soil by over 90 percent by putting it in plastic bags and burying it 10 to 20 centimeters in the earth. The national government says it will give instructions on what to do with contaminated soil, but for the time being, it is asking local governments to secure temporary storage sites. However, local governments are struggling to win the agreement of local residents to host such sites.

For areas with over 20 millisieverts of radiation per year, the national government has said it will handle decontamination work itself, but details and an estimate for completion have not been released.

(Mainichi Japan) September 18, 2011

TEPCO scraps plan to raise power charges 10-15%

TOKYO (Kyodo) -- Tokyo Electric Power Co. has decided to scrap its plan to raise electricity charges 10 to 15 percent from next April due to **growing criticism among government officials and the public**, company sources said Saturday.

The operator of the crisis-hit Fukushima No. 1 nuclear power complex previously planned to raise charges to keep its financial standing from being seriously hurt due to payment of damage compensation over the nuclear crisis.

The utility has already informed its creditor banks about the decision, the sources said. The company known as TEPCO may propose a smaller increase in charges instead when its power generation cost is sure to rise further once regular inspections begin for more of its nuclear reactors still in service and its increased use of fossil fuel.

TEPCO has informally told a government committee that has been assessing the utility's assets and costs about the plan to raise charges by up to 15 percent for three years. But committee members have agreed not to allow the company to lift electricity charges unless additional steps are considered to cut pension payments, employees' salaries and other costs.

(Mainichi Japan) September 18, 2011

Future radiation levels forecast on electronic map

A group of Japanese researchers has drawn up an electronic map which shows changing radiation levels at about 2,200 locations in a 5-year period.

The map was made by a research group led by Professor Isao Tanihata at Osaka University's Research Center for Nuclear Physics.

The group calculated estimated radiation levels at each of about 2,200 points over the next 5 years based on data released by the education and science ministry.

Most of the locations are in Fukushima Prefecture, where a nuclear accident was triggered in March by the massive earthquake and tsunami.

The group took into account the level of radioactive cesium, which drops as time passes.

By using Google Earth services, the group forecast the level at individual sites and point of time with a bar graph. Possible changes in level naturally caused by rain and wind and the decontamination effort

are not included.

For example, the map shows that a radiation level of 4.36 microsieverts per hour detected in June in Kawamata Town about 30 kilometers northwest of the troubled plant will fall to 1.75 microsieverts 5 years later.

Professor Tanihata hopes that the map will help state and local authorities to work out a specific plan to decontaminate areas to get people to return to their hometowns.

The map will be made public at the research center's Website on Monday.

Sunday, September 18, 2011 14:59 +0900 (JST)

Cesium detected in 4% of tested rice

Radioactive tests on rice have been completed in more than half of the Tohoku and Kanto regions, and radioactive cesium has been detected in 4 percent of the samples. But the highest level detected so far is about a quarter of the government's safety limit.

Based on the interim results, shipments of rice have started in municipalities in 15 prefectures.

A preliminary examination is conducted while the rice is still growing and another test is carried out after the harvest. Rice can only be shipped if the amounts of cesium in the post-harvest test are below the **government-set safety limit of 500 becquerels per kilogram in all the locations within a municipality.**

Preliminary tests have been completed in 7 prefectures, but not in Fukushima or Miyagi.

Radioactive cesium has been detected in 72 places so far, including 64 locations in Fukushima Prefecture, where the Fukushima Daiichi power plant is located. But the highest level detected was 136 becquerels per kilogram, which is about a quarter of the government's safety limit.

The main test is being conducted in 17 prefectures, and has been completed in more than half of them. Radioactive materials were detected in rice harvested in 22 locations. But the highest level detected so far is 101.6 becquerels per kilogram, or one fifth of the government's safety limit.

With the preliminary and main tests combined, the results are known for more than 60 percent of the test locations. Radioactive materials have been detected in 94 locations, or 4.3 percent of the total.

Shipments of rice have started in municipalities in 15 prefectures, including all 52 municipalities in Chiba Prefecture.

In Fukushima Prefecture, shipments of ordinary rice have started in 2 municipalities, and those of early-harvested rice in 20 municipalities.

Kenzaburo Oe: Resignation to and responsibility for Fukushima disaster

It hasn't been long since I read a science fiction piece in which humankind decides to bury massive amounts of radioactive waste deep underground. They are stumped by how they should warn the people of the future who will be left to deal with the waste, and by who should sign the warning.

Unfortunately, the situation is no longer a matter of fiction. **We are one-sidedly unloading our burdens onto future generations.** When did humankind abandon the morals that would stop us from doing such a thing? Have we passed a fundamental turning point in history?

After March 11, I stayed up until late every night watching television (a newly formed habit following the disaster). There was a television reporter who went to check in on a house with the lights on in an area that was otherwise dark due to evacuation orders. As it turned out, a horse was in labor and the owner was unable to leave its side. Several days later, the reporter visited the farm once again, and saw the mare and its foal indoors in the dark. Their owner's expression was gloomy. The foal had not been allowed outside to run around freely because radioactive material-contaminated rain had fallen on the grass.

The crisis has taken away lives that many people are still trying to get back. What messages can we deliver to those people and how? I need to hear those words, too, and the person I have turned to for guidance is the physician Shuntaro Hida, who has been speaking about the dangers of internal exposure to radiation since the atomic bombing of Hiroshima.

In an interview in the September issue of the magazine Sekai, Hida says: "If you have already been exposed, you must be prepared. Resign yourself. Tell yourself that you might be unlucky and see horrendous effects several decades down the line. Then, try to build up your immune system as much as you can to fight the hazards of radiation.

"But will making the effort to avoid buying vegetables that may be tainted be sufficient in protecting you? **It's better to take precautions than to not take them.** But radioactive materials continue to leak from Fukushima, even now. Tainted food has infiltrated the market, so unfortunately, there's no guaranteed method of protecting yourself from internal exposure. Abolishing nuclear power and cutting off radioactivity at its source is a much faster way of dealing with it."

I do not want to deliver these words to the men -- the politicians, the bureaucrats, the businessmen -- who intend to thrust the difficult task of dealing with radioactive waste, which was generated and continues to be generated by an electric power policy that puts production power and economic strength before everything else, upon future generations. Rather, I want to deliver these words to the women -- the young mothers -- who have been quick to catch on to the dangers being posed to their children, and are trying to deal with the problem head on.

After Italian voters rejected the resumption of operations at their nuclear power plants, a senior official in Japan's Liberal Democratic Party (LDP) attributed the referendum result to "mass hysteria," suggesting that the power of women was behind the results. An Italian woman in the film industry responded to the insult, saying: "Japanese men are likely moved to action by a 'mass hysteria' that puts productivity and economic power before all else. I'm only talking about men here, because no matter

where you are, women never put anything before life. If Japan were to not only lose its status as an economic superpower but fall into long-term poverty, we all know from Japanese films that women will overcome such hardships!"

The bombings of Hiroshima and Nagasaki, Japan's World War II defeat, and the subsequent occupation of Japan by the Allied Forces took place during my childhood. We were all poor. But when the new Constitution was unveiled, I was struck by the repetition of the word "determination" in its preamble. It filled me with pride to know that the grown-ups were so resolute. Today, through the eyes of an old man, I see Fukushima and the difficult circumstances that this country faces. And still I have hope in a new resolve of the Japanese people. (By Kenzaburo Oe, author)

Kenzaburo Oe, born 1935, was awarded the 1994 Nobel Prize for Literature. After the crisis started at the Fukushima No. 1 Nuclear Power Plant, musicians and writers, including Oe, released a statement calling for the abolishment of nuclear power. An antinuclear rally will be held in Tokyo's Meiji Park on Sept. 19.

(Mainichi Japan) September 19, 2011

Noda to emphasize continuing need for nuclear plants in Japan at U.N.

TOKYO (Kyodo) -- Prime Minister Yoshihiko Noda is set to emphasize the continuing need for nuclear power plants in Japan and will pledge to ensure the highest level of operational safety during an upcoming U.N. conference, according to a draft of his speech obtained by Kyodo News on Sunday.

Noda will adopt a different position to that of his predecessor Naoto Kan, who sought to reduce the country's reliance on nuclear power in the wake of the crisis at the Fukushima Daiichi power plant.

According to the draft, Noda will tell a session of the U.N. high-level meeting on nuclear safety and security on Thursday that his government will "raise the safety of nuclear plants to the highest level."

Noda will also say, "There will be a continuing necessity to secure nuclear energy that is safe and more reliable," while promising a thorough investigation into what caused the world's worst nuclear accident in 25 years and to fully disclose information.

"There is a consensus among the international community that enhancing safety measures related to nuclear energy should take priority," Noda is expected to say.

The premier will also stress his resolve to enhance measures aimed at protecting nuclear plants and materials to underscore Japan's intention to work with the United States on the issue at the United Nations.

U.S. President Barack Obama had urged Japan to make efforts to ensure nuclear safety in a letter to Kan.

Noda will also say that Japan will work on developing and promoting renewable energy as well as decontaminating areas affected by the Fukushima nuclear crisis triggered by the March 11 earthquake and tsunami.

On overall energy policy, Noda will pledge to speed up work on mapping out concrete measures, including target ratios for various renewable energy sources, saying, "We will release a best energy mix shortly."

(Mainichi Japan) September 19, 2011

Kan told Tokyo residents may have to evacuate due to nuclear crisis

TOKYO (Kyodo) -- Former Prime Minister Naoto Kan said in a recent interview with Kyodo News that he learned shortly after the nuclear crisis erupted at the Fukushima Daiichi power plant that around 30 million people in Tokyo and surrounding prefectures may have to be evacuated in a worst-case scenario.

Kan said he contemplated the chaos that would have ensued if such a measure had been taken. "It was a crucial moment when I wasn't sure whether Japan could continue to function as a state," he said.

After the March 11 earthquake and tsunami crippled the plant, Kan instructed several entities to simulate what would happen in a worst-case scenario and received assessments that people living in areas located 200 to 250 kilometers from the power plant, encompassing a large swath of Tokyo, would have to be evacuated.

"I felt that the risk was at its highest during the first 10 days (after the disaster struck)," said Kan, who resigned as prime minister earlier this month.

He also said when the disaster occurred, there were no effective safeguards in place because "We had never foreseen a situation in which a quake, tsunami and a nuclear plant accident would occur at the same time."

Concerning Tokyo Electric Power Co.'s failure on March 11 to immediately perform "venting" to release radioactive steam from the nuclear reactors at the plant, despite his repeated requests, Kan said,

"Even TEPCO officials (who were with me) at the prime minister's office were unable to fully explain why they were not doing the venting, so I wasn't sure whether there was good communication between the TEPCO head office and the Fukushima plant."

Because of this, Kan said, he went to inspect the Fukushima plant the following day.

Upon hearing on March 15 that TEPCO wanted to evacuate the workers at the Fukushima plant, Kan said, "I thought that was impossible." He subsequently rejected TEPCO's request.

(Mainichi Japan) September 19, 2011

Siemens to leave nuclear industry

German industrial and engineering giant Siemens is withdrawing from the nuclear industry following the German government's decision to phase out nuclear power generation.

Chief Executive Peter Loescher revealed the plan in an interview in the edition of the German weekly magazine "Der Spiegel" published on Sunday.

Loescher said the company will no longer be involved with construction of nuclear power stations. He said the decision is the company's answer to the clear positioning of Germany's society and government for a pullout from nuclear energy.

He said the company will still produce steam turbines and other parts for non-nuclear facilities such as gas-fired power stations.

Siemens is the first major nuclear power equipment manufacturer to withdraw from the nuclear industry.

The German government decided in June to shut down all of the country's 17 nuclear reactors by 2022 in light of the accident at the Fukushima Daiichi Nuclear Power Station in Japan in March.

Monday, September 19, 2011 09:28 +0900 (JST)

Thousands march against nuclear power in Tokyo

TOKYO (AP) -- Several thousand people are marching in downtown Tokyo calling on the government to abandon nuclear energy in the wake of the Fukushima nuclear accident.

The demonstrators chanted "Sayonara nuclear power" while holding banners and placards as they marched Monday, a national holiday in Japan.

Police gave an initial estimate that just over 20,000 people participated, but protest organizers put the figure at 60,000.

Either way, it is one of the biggest demonstrations since the March 11 accident, in which the tsunami-damaged Fukushima Dai-ichi power plant spewed radiation into the air in the worst nuclear disaster since Chernobyl.

(Mainichi Japan) September 19, 2011

Density of cesium over Fukushima plant's No. 2 reactor declines sharply

The density of cesium and other radioactive materials in the air over the Fukushima No. 1 nuclear plant's No. 2 reactor has dropped radically, Tokyo Electric Power Co. (TEPCO) said on Sept. 18.

Samples taken Sept. 17 from two openings at the top of the No.2 reactor building showed that the cesium density was one-10,000th to one-100,000th of a becquerel per cubic centimeter, a sharp decline from the end of August.

TEPCO said the density of cesium-134 and cesium-137 was less than one-100th of the permissible level and that of iodine-131 was below the detectable level.

Commenting on the drops in radioactive substance densities, TEPCO said, "The release (of radioactive substances) has been curtailed due to the ongoing cooling of the reactor, but wind outside the building may have influenced (the results)."

(Mainichi Japan) September 19, 2011

Largest antinuclear rally held in Tokyo since Fukushima crisis

TOKYO (Kyodo) -- Tens of thousands of people took to the streets in downtown Tokyo on Monday to call for the shutdown of all nuclear power plants in Japan, in the largest protest rally in the country since the Fukushima Daiichi plant catastrophe.

Nobel Prize-winning novelist Kenzaburo Oe, journalist Satoshi Kamata and actor Taro Yamamoto were among the speakers to address the crowd, which organizers put at 60,000 people. Tokyo police estimated the crowd at half that size, or 30,000 people.

"We need to let leaders of major parties and the Japan Business Federation know our intention to resist" nuclear power generation, Oe, a leading organizer of the event, told the gathering at Tokyo's Meiji Park.

Ruiko Muto, a 58-year-old activist who leads a movement to dismantle nuclear reactors in Fukushima Prefecture, delivered a more personal message.

"To escape or not to escape? To eat or not to eat? I was forced to make such choices every day" since the March earthquake and tsunami crippled the plant, said Muto.

The March 11 natural disasters knocked out all power supplies to the Fukushima Daiichi nuclear plant, leading to explosions that damaged three reactor buildings. The massive amount of radioactive material that escaped prompted the emergency evacuation of thousands of people living in surrounding communities, and concern about radioactive food contamination.

Muto urged people not to forget that a nuclear power plant is behind any power outlet.

"Each of us has to decide and act in order to achieve a life at the opposite extreme of nuclear power generation."

Yamamoto as a guest speaker said, "We already have sufficient electricity (even without nuclear plants). If we do nothing now, Japan will be a disposal site of nuclear waste."

Later participants split into three groups and marched in Tokyo, including through the fashionable district of Omotesando to protest against nuclear power generation.

Japan vows at IAEA confab to stabilize Fukushima Daiichi by year-end

VIENNA (Kyodo) -- Japan pledged Monday to move up the deadline for bringing the crippled Fukushima Daiichi nuclear power plant to a stable condition, telling an International Atomic Energy Agency conference it will do so by year-end.

Goshi Hosono, Japan's minister in charge of the nuclear accident, revealed the revised schedule at the annual conference of the U.N. nuclear watchdog. Japan previously said it would bring the plant to a condition known as "cold shutdown" by mid-January.

"We will move up the existing target period, and endeavor to achieve this 'cold shutdown' by the end of this year," Hosono said.

Hosono made the promise as the government and Tokyo Electric Power Co., the operator of the Fukushima plant, plan to update the current timeline Tuesday.

Hosono also said that the Japanese government is working to set up a Nuclear Safety and Security Agency in next April as an external body of the Environment Ministry to fully achieve "separation of authorities for regulation and promotion" of nuclear power.

Japan will subsequently accept an IAEA team sent to assess how effectively the new entity will function, Hosono said.

The IAEA began a five-day conference on Monday convened to endorse an action plan that its board of governors adopted last week and meant to enhance global nuclear safety in the aftermath of the Fukushima disaster. The conference will also discuss a draft resolution on the scrapping of North Korea's nuclear programs.

On the sidelines of the conference, Hosono said in a meeting with IAEA chief Yukiya Amano that he agreed that Japan will accept a team of IAEA experts in October sent to advise on decontaminating areas near the radiation-leaking Fukushima plant.

Japan also agreed to seek the agency's assistance in assessing safety measures related to the restart of atomic power plants in Japan currently shut down for regular checkups, Hosono said.

(Mainichi Japan) September 20, 2011

Hosono: Cooling down to be achieved this year

Japan's minister in charge of the nuclear disaster says reactors at the troubled Fukushima Daiichi plant will be cooled to below 100 degrees Celsius within this year.

Goshi Hosono spoke at the International Atomic Energy Agency's annual ministerial meeting on Monday.

He thanked the international community for assisting Japan in dealing with the accident at Fukushima.

Hosono said that decontaminated water has been successfully used to cool down the troubled nuclear reactors, bringing the temperature close to 100 degrees Celsius. He also said spent nuclear fuel pools have been cooled in a stable manner.

Hosono also said the spent nuclear fuel has been steadily cooled and will fall below 100 degrees by the end of this year, instead of early next year as initially predicted.

When the reactors and spent fuel have been cooled below 100 degrees, radiation emissions can be kept very low.

The minister also said Japan will work with the IAEA to remove radioactive materials from areas near Fukushima Daiichi.

He explained the plan to separate the Nuclear and Industrial Safety Agency from the Economy, Trade and Industry Ministry, saying it will be merged with the Cabinet Office's Nuclear Safety Commission to create a nuclear safety agency under the Environment Ministry by next April.

Tuesday, September 20, 2011 07:00 +0900 (JST)

Hosono seeks US, French help to scrap reactors

Japan's cabinet minister in charge of the nuclear disaster has asked the United States and France for help in scrapping the reactors at the Fukushima Daiichi power plant.

Goshi Hosono on Monday held separate meetings with US Nuclear Regulatory Commission Chairman Gregory Jaczko, US Energy Secretary Steven Chu and French Industry Minister Eric Besson in Vienna. They are in the Austrian capital for the general assembly of the International Atomic Energy Agency.

Hosono told the officials that the Japanese government is aiming for a cold shutdown of the Fukushima plant before the end of the year.

The government's plan to stabilize the plant originally called for achieving a cold shutdown early next year.

Hosono asked the US and French officials to help with essential work after the cold shutdown,

including scrapping the reactors, decontaminating soil and disposing of radioactive waste.

The officials responded positively.

Tuesday, September 20, 2011 07:00 +0900 (JST)

IAEA to send experts to Japan

The International Atomic Energy Agency says it will send experts to Japan to cooperate in the removal of radioactive materials in Fukushima Prefecture.

IAEA chief Yukiya Amano made the remarks on Monday in Vienna. He was responding to a request from Japan's nuclear crisis minister, Goshi Hosono.

Hosono said Japan needs international experience and expertise in order to make progress in the removal of radioactive materials in areas near the Fukushima Daiichi nuclear plant.

He also asked the IAEA for advice regarding stress tests for nuclear reactors in preparation for their restart after checkups. Amano said the agency will help.

After the meeting, Hosono said Japan is removing radioactive materials on a scale that no country has ever experienced.

He went on to say his country will seek advice from the IAEA on how to win public support for the restart of its safety-checked nuclear plants until its new nuclear safety agency is established.

Tuesday, September 20, 2011 07:00 +0900 (JST)

Groundwater flowing into Fukushima nuclear plant

TOKYO (Kyodo) -- Tokyo Electric Power Co. said Tuesday it suspects that 200 to 500 tons a day of groundwater might be flowing through pits and wall cracks into reactor and turbine buildings at the Fukushima Daiichi nuclear plant crippled by the March 11 earthquake and tsunami.

The suspicion is based on the fact that a decline in water levels in these buildings has slowed down.

"The suspected groundwater inflow is now unlikely to cause problems as the plant is capable of treating nearly 1,000 tons of radiation-contaminated water," said an official at the company known as TEPCO.

But the inflow is expected to affect efforts to contain the Fukushima nuclear crisis. "We should assess the groundwater inflow and readjust an overall plan for treating contaminated water," said an official of the Nuclear and Industrial Safety Agency at the Ministry of Economy, Trade and Industry.

(Mainichi Japan) September 20, 2011

TEPCO:Groundwater may be flowing into plant

The Tokyo Electric Power Company, or TEPCO, says a large amount of groundwater may be entering the crippled Fukushima Daiichi nuclear power plant.

TEPCO says it has found that 200 to 500 tons of what is probably rainwater that seeped into soil may be entering daily through cracks in walls into the basements of buildings housing reactors and turbines.

The utility says it's worried that this will increase the amount of highly radioactive water in the basements.

Workers at the plant are injecting about 550 tons of water a day to cool 3 of its damaged reactors. About 80,000 tons of highly radioactive water has already accumulated in the buildings.

TEPCO says it plans to keep levels of radioactive water lower than those of groundwater to stop further inflows.

The government's Nuclear Safety Agency says groundwater inflow must be considered in drawing up a long-term decontamination plan.

Tuesday, September 20, 2011 17:31 +0900 (JST)

A new plan set to reduce radiation emissions

The Japanese government and the operator of the troubled Fukushima Daiichi nuclear plant say they will install new devices to reduce the amount of radioactive substances released into the air.

The government and Tokyo Electric Power Company, TEPCO, originally planned to achieve a cold shutdown, in which temperatures of the reactors reach below 100 degrees Celsius by January next year.

They now say that they will aim to reach that status within this year, as their work is making steady progress.

The government and TEPCO revealed the plan in their monthly review of the timetable for containing the nuclear crisis.

They will install new devices at the NO.1, No.2 and No.3 reactors to take contaminated gases out of the reactors using filters. They plan to start installing the devices next week.

TEPCO also plans to complete the construction of a giant polyester shield over the No.1 reactor by mid-October.

The operator also plans to improve its cooling systems so that the temperatures of all 3 reactors will drop below 100 degrees Celsius.

They say the amount of radioactive substances released from the plant was about 200-million becquerels per hour in the first half of September. They say that's about one-four millionths of the level of the initial stages of the accident in March.

Tuesday, September 20, 2011 20:02 +0900 (JST)

65 percent of Japanese prefer to cut electricity use even if living standards drop

(Mainichi Japan) September 20, 2011 -

<http://mdn.mainichi.jp/mdnnews/news/20110920p2a00m0na017000c.html>

Sixty-five percent of Japanese people think that they should reduce their use of electricity even if their living standards have to be lowered in the wake of the outbreak of the crisis at the Fukushima No. 1 Nuclear Power Plant, according to a recent survey conducted by the Mainichi Shimbun.

A survey of 2,413 people, conducted in an interview format by the Mainichi from Sept. 2 to 4, shows 65 percent of the respondents prefer to cut electricity use even if they have to lower their standards of living. The survey did not cover people in Iwate, Miyagi and Fukushima prefectures hit hard by the March 11 disasters. Thirty-two percent of the people polled said power supply should be increased in order to maintain their standard of living.

The survey also shows that most people want to see nuclear power being phased out, with 60 percent of the respondents preferring to gradually reduce the number of nuclear reactors while halting the operations of high-risk reactors.

By gender, 60 percent of male respondents and 70 percent of female respondents said the use of electricity should be reduced even if the standards of living have to be lowered. By age groups, relatively young people tend to think the use of electricity should be cut at the expense of living standards, with 71 percent of those in their 30s and 67 percent of those in their 20s sharing such views. Of those respondents who put priority on cutting electricity consumption rather than on maintaining current living standards, 66 percent of them said the number of nuclear reactors should be gradually reduced.

On the question of what should be done to the nuclear reactors in the future, 60 percent of those surveyed said the number of reactors should be reduced gradually, while 20 percent said the nuclear reactors should be operated without increasing the number of reactors. Twelve percent of the respondents said all reactors should be stopped as soon as possible, while 6 percent said the existing reactors should be operated and new reactors should be built. The survey shows 70 percent of people seeking an end to the country's reliance on nuclear power generation.

On a plan to have a backup of Tokyo's capital functions to prepare for large-scale natural disasters, only 10 percent of the respondents said no backup would be necessary, while 43 percent said a backup should be created in Kansai, followed by 18 percent for Kanto outside of the metropolitan area and 9 percent for Tokai.

Because of the widespread impact of the Great East Japan Earthquake, many people prefer to have a backup of the capital's functions in Kansai rather than in Kanto and Tokai. Osaka Gov. Toru Hashimoto told Tokyo Gov. Shintaro Ishihara in July that he would try to make Osaka a backup for Tokyo's capital functions.

Local governments in Fukushima experiment with radiation-removing techniques

Workers experiment with draining radioactively contaminated mud from a paddy field, left, onto a tarp-covered adjacent field in Iitate, Fukushima Prefecture, on Aug. 24. (Mainichi)

Local governments in Fukushima Prefecture are experimenting with efforts to remove radioactive material spread from the crippled nuclear power plant following a request by the national government.

In August, the national government asked that local governments handle decontamination work in areas with under 20 millisieverts of radiation per year.

At a farm house in the Onami district of the city of Fukushima with mountains behind it and rice paddy fields surrounding it, the Fukushima Prefectural Government experimented with decontamination techniques in late August.

Seven painters used to working at heights participated in the experiment. Wearing helmets, boots and rubber gloves and tied with safety ropes, they used high-pressure hoses to spray the entire roof with water. At one point, one of the painters slipped and lost his balance.

"This is **too dangerous for regular people to do**," muttered Hisashi Katayose, chief of the prefecture's nuclear energy safety department, as he watched on.

Workers focused their cleaning efforts on the roof, walls, and rain gutters of the house. They hoped doing so would also reduce radiation levels in the bedroom on the second floor and the living room on the first floor.

After working for around three hours, the greatest drop in radiation levels was measured in the rain gutter on the side of the house facing the mountains. The levels had fallen from 14.5 microsieverts per

hour to 1.8 microsieverts per hour. However, the second-floor bedroom's radiation level barely changed, falling from 0.7 microsieverts per hour to 0.61 microsieverts per hour.

Katayose was disappointed with the results. The area where he had most wanted to see dropped radiation levels -- the bedroom, since that is where much of a resident's time would be spent -- did not show the results he had anticipated.

Those conducting the experiments judged that radiation from the mountain slopes at the back, the garden by the house or other areas that weren't decontaminated were continuing to affect the readings. Additional efforts, using different techniques and targeting different locations, would be needed to lower the indoor levels.

"Decontamination work requires incredible money and patience," says Katayose. "The national government and Tokyo Electric Power Company should take responsibility for it, rather than leaving it to local governments."

Giving the Fukushima Prefectural Government advice on decontamination work is Hiroshi Kurigami of the Japan Atomic Energy Agency (JAEA). "They should approach it in the same way as cleaning a house," he says. According to Kurigami, in addition to wearing masks and gloves to reduce radiation exposure, those doing decontamination work should work from top to bottom, the same way that those dusting a room should.

He says that in decontaminating a house, one should first remove the leaves from trees around the house. Next, one should remove the topsoil and fallen leaves from around the home. After that, one should remove the bushes and other small plants, especially those under the eaves of the house. The drain by the road should be emptied of dirt before it is washed. For cleaning surfaces, a high-pressure hose is useful, but a scrubbing brush can be more effective in removing material.

"If levels haven't fallen even after repeated decontamination, one should consult an expert," Kurigami says.

Fukushima Prefecture is sending experts on request from neighborhood associations to help with decontamination efforts. Furthermore, the Japanese Society of Radiation Safety Management (JRSM) is offering detailed decontamination advice and consultations with experts through their website.

Additionally, the National Institute for Rural Engineering has been working to drain mud containing radioactive cesium from rice paddy fields in the village of Iitate, Fukushima Prefecture. The JAEA has developed a technique to decontaminate pools using the mineral zeolite, which can absorb radioactive cesium, and is using the technique in Fukushima Prefecture.

Another issue is what to do with contaminated soil and other remains of decontamination work. According to the JRSM, they were able to reduce the radiation coming from contaminated soil by over 90 percent by putting it in plastic bags and burying it 10 to 20 centimeters in the earth. The national government says it will give instructions on what to do with contaminated soil, but for the time being, it is asking local governments to secure temporary storage sites. However, local governments are struggling to win the agreement of local residents to host such sites.

For areas with over 20 millisieverts of radiation per year, the national government has said it will handle decontamination work itself, but details and an estimate for completion have not been released.

(Mainichi Japan) September 18, 2011

TEPCO scraps plan to raise power charges 10-15%

TOKYO (Kyodo) -- Tokyo Electric Power Co. has decided to scrap its plan to raise electricity charges 10 to 15 percent from next April due to **growing criticism among government officials and the public**, company sources said Saturday.

The operator of the crisis-hit Fukushima No. 1 nuclear power complex previously planned to raise charges to keep its financial standing from being seriously hurt due to payment of damage compensation over the nuclear crisis.

The utility has already informed its creditor banks about the decision, the sources said. The company known as TEPCO may propose a smaller increase in charges instead when its power generation cost is sure to rise further once regular inspections begin for more of its nuclear reactors still in service and its increased use of fossil fuel.

TEPCO has informally told a government committee that has been assessing the utility's assets and costs about the plan to raise charges by up to 15 percent for three years. But committee members have agreed not to allow the company to lift electricity charges unless additional steps are considered to cut pension payments, employees' salaries and other costs.

(Mainichi Japan) September 18, 2011

Future radiation levels forecast on electronic map

A group of Japanese researchers has drawn up an electronic map which shows changing radiation levels at about 2,200 locations in a 5-year period.

The map was made by a research group led by Professor Isao Tanihata at Osaka University's Research Center for Nuclear Physics.

The group calculated estimated radiation levels at each of about 2,200 points over the next 5 years based on data released by the education and science ministry.

Most of the locations are in Fukushima Prefecture, where a nuclear accident was triggered in March by the massive earthquake and tsunami.

The group took into account the level of radioactive cesium, which drops as time passes.

By using Google Earth services, the group forecast the level at individual sites and point of time with a bar graph. Possible changes in level naturally caused by rain and wind and the decontamination effort

are not included.

For example, the map shows that a radiation level of 4.36 microsieverts per hour detected in June in Kawamata Town about 30 kilometers northwest of the troubled plant will fall to 1.75 microsieverts 5 years later.

Professor Tanihata hopes that the map will help state and local authorities to work out a specific plan to decontaminate areas to get people to return to their hometowns.

The map will be made public at the research center's Website on Monday.

Sunday, September 18, 2011 14:59 +0900 (JST)

Cesium detected in 4% of tested rice

Radioactive tests on rice have been completed in more than half of the Tohoku and Kanto regions, and radioactive cesium has been detected in 4 percent of the samples. But the highest level detected so far is about a quarter of the government's safety limit.

Based on the interim results, shipments of rice have started in municipalities in 15 prefectures.

A preliminary examination is conducted while the rice is still growing and another test is carried out after the harvest. Rice can only be shipped if the amounts of cesium in the post-harvest test are below the **government-set safety limit of 500 becquerels per kilogram in all the locations within a municipality.**

Preliminary tests have been completed in 7 prefectures, but not in Fukushima or Miyagi.

Radioactive cesium has been detected in 72 places so far, including 64 locations in Fukushima Prefecture, where the Fukushima Daiichi power plant is located. But the highest level detected was 136 becquerels per kilogram, which is about a quarter of the government's safety limit.

The main test is being conducted in 17 prefectures, and has been completed in more than half of them. Radioactive materials were detected in rice harvested in 22 locations. But the highest level detected so far is 101.6 becquerels per kilogram, or one fifth of the government's safety limit.

With the preliminary and main tests combined, the results are known for more than 60 percent of the test locations. Radioactive materials have been detected in 94 locations, or 4.3 percent of the total.

Shipments of rice have started in municipalities in 15 prefectures, including all 52 municipalities in Chiba Prefecture.

In Fukushima Prefecture, shipments of ordinary rice have started in 2 municipalities, and those of early-harvested rice in 20 municipalities.

Sunday, September 18, 2011 22:23 +0900 (JST)

Kenzaburo Oe: Resignation to and responsibility for Fukushima disaster

It hasn't been long since I read a science fiction piece in which humankind decides to bury massive amounts of radioactive waste deep underground. They are stumped by how they should warn the people of the future who will be left to deal with the waste, and by who should sign the warning.

Unfortunately, the situation is no longer a matter of fiction. **We are one-sidedly unloading our burdens onto future generations.** When did humankind abandon the morals that would stop us from doing such a thing? Have we passed a fundamental turning point in history?

After March 11, I stayed up until late every night watching television (a newly formed habit following the disaster). There was a television reporter who went to check in on a house with the lights on in an area that was otherwise dark due to evacuation orders. As it turned out, a horse was in labor and the owner was unable to leave its side. Several days later, the reporter visited the farm once again, and saw the mare and its foal indoors in the dark. Their owner's expression was gloomy. The foal had not been allowed outside to run around freely because radioactive material-contaminated rain had fallen on the grass.

The crisis has taken away lives that many people are still trying to get back. What messages can we deliver to those people and how? I need to hear those words, too, and the person I have turned to for guidance is the physician Shuntaro Hida, who has been speaking about the dangers of internal exposure to radiation since the atomic bombing of Hiroshima.

In an interview in the September issue of the magazine Sekai, Hida says: "If you have already been exposed, you must be prepared. Resign yourself. Tell yourself that you might be unlucky and see horrendous effects several decades down the line. Then, try to build up your immune system as much as you can to fight the hazards of radiation.

"But will making the effort to avoid buying vegetables that may be tainted be sufficient in protecting you? **It's better to take precautions than to not take them.** But radioactive materials continue to leak from Fukushima, even now. Tainted food has infiltrated the market, so unfortunately, there's no guaranteed method of protecting yourself from internal exposure. Abolishing nuclear power and cutting off radioactivity at its source is a much faster way of dealing with it."

I do not want to deliver these words to the men -- the politicians, the bureaucrats, the businessmen -- who intend to thrust the difficult task of dealing with radioactive waste, which was generated and continues to be generated by an electric power policy that puts production power and economic strength before everything else, upon future generations. Rather, I want to deliver these words to the women -- the young mothers -- who have been quick to catch on to the dangers being posed to their children, and are trying to deal with the problem head on.

After Italian voters rejected the resumption of operations at their nuclear power plants, a senior official in Japan's Liberal Democratic Party (LDP) attributed the referendum result to "mass hysteria," suggesting that the power of women was behind the results. An Italian woman in the film industry responded to the insult, saying: "Japanese men are likely moved to action by a 'mass hysteria' that puts productivity and economic power before all else. I'm only talking about men here, because no matter

where you are, women never put anything before life. If Japan were to not only lose its status as an economic superpower but fall into long-term poverty, we all know from Japanese films that women will overcome such hardships!"

The bombings of Hiroshima and Nagasaki, Japan's World War II defeat, and the subsequent occupation of Japan by the Allied Forces took place during my childhood. We were all poor. But when the new Constitution was unveiled, I was struck by the repetition of the word "determination" in its preamble. It filled me with pride to know that the grown-ups were so resolute. Today, through the eyes of an old man, I see Fukushima and the difficult circumstances that this country faces. And still I have hope in a new resolve of the Japanese people. (By Kenzaburo Oe, author)

Kenzaburo Oe, born 1935, was awarded the 1994 Nobel Prize for Literature. After the crisis started at the Fukushima No. 1 Nuclear Power Plant, musicians and writers, including Oe, released a statement calling for the abolishment of nuclear power. An antinuclear rally will be held in Tokyo's Meiji Park on Sept. 19.

(Mainichi Japan) September 19, 2011

Noda to emphasize continuing need for nuclear plants in Japan at U.N.

TOKYO (Kyodo) -- Prime Minister Yoshihiko Noda is set to emphasize the continuing need for nuclear power plants in Japan and will pledge to ensure the highest level of operational safety during an upcoming U.N. conference, according to a draft of his speech obtained by Kyodo News on Sunday.

Noda will adopt a different position to that of his predecessor Naoto Kan, who sought to reduce the country's reliance on nuclear power in the wake of the crisis at the Fukushima Daiichi power plant.

According to the draft, Noda will tell a session of the U.N. high-level meeting on nuclear safety and security on Thursday that his government will "raise the safety of nuclear plants to the highest level."

Noda will also say, "There will be a continuing necessity to secure nuclear energy that is safe and more reliable," while promising a thorough investigation into what caused the world's worst nuclear accident in 25 years and to fully disclose information.

"There is a consensus among the international community that enhancing safety measures related to nuclear energy should take priority," Noda is expected to say.

The premier will also stress his resolve to enhance measures aimed at protecting nuclear plants and materials to underscore Japan's intention to work with the United States on the issue at the United Nations.

U.S. President Barack Obama had urged Japan to make efforts to ensure nuclear safety in a letter to Kan.

Noda will also say that Japan will work on developing and promoting renewable energy as well as decontaminating areas affected by the Fukushima nuclear crisis triggered by the March 11 earthquake and tsunami.

On overall energy policy, Noda will pledge to speed up work on mapping out concrete measures, including target ratios for various renewable energy sources, saying, "We will release a best energy mix shortly."

(Mainichi Japan) September 19, 2011

Kan told Tokyo residents may have to evacuate due to nuclear crisis

TOKYO (Kyodo) -- Former Prime Minister Naoto Kan said in a recent interview with Kyodo News that he learned shortly after the nuclear crisis erupted at the Fukushima Daiichi power plant that around 30 million people in Tokyo and surrounding prefectures may have to be evacuated in a worst-case scenario.

Kan said he contemplated the chaos that would have ensued if such a measure had been taken. "It was a crucial moment when I wasn't sure whether Japan could continue to function as a state," he said.

After the March 11 earthquake and tsunami crippled the plant, Kan instructed several entities to simulate what would happen in a worst-case scenario and received assessments that people living in areas located 200 to 250 kilometers from the power plant, encompassing a large swath of Tokyo, would have to be evacuated.

"I felt that the risk was at its highest during the first 10 days (after the disaster struck)," said Kan, who resigned as prime minister earlier this month.

He also said when the disaster occurred, there were no effective safeguards in place because "We had never foreseen a situation in which a quake, tsunami and a nuclear plant accident would occur at the same time."

Concerning Tokyo Electric Power Co.'s failure on March 11 to immediately perform "venting" to release radioactive steam from the nuclear reactors at the plant, despite his repeated requests, Kan said,

"Even TEPCO officials (who were with me) at the prime minister's office were unable to fully explain why they were not doing the venting, so I wasn't sure whether there was good communication between the TEPCO head office and the Fukushima plant."

Because of this, Kan said, he went to inspect the Fukushima plant the following day.

Upon hearing on March 15 that TEPCO wanted to evacuate the workers at the Fukushima plant, Kan said, "I thought that was impossible." He subsequently rejected TEPCO's request.

(Mainichi Japan) September 19, 2011

Siemens to leave nuclear industry

German industrial and engineering giant Siemens is withdrawing from the nuclear industry following the German government's decision to phase out nuclear power generation.

Chief Executive Peter Loescher revealed the plan in an interview in the edition of the German weekly magazine "Der Spiegel" published on Sunday.

Loescher said the company will no longer be involved with construction of nuclear power stations. He said the decision is the company's answer to the clear positioning of Germany's society and government for a pullout from nuclear energy.

He said the company will still produce steam turbines and other parts for non-nuclear facilities such as gas-fired power stations.

Siemens is the first major nuclear power equipment manufacturer to withdraw from the nuclear industry.

The German government decided in June to shut down all of the country's 17 nuclear reactors by 2022 in light of the accident at the Fukushima Daiichi Nuclear Power Station in Japan in March.

Monday, September 19, 2011 09:28 +0900 (JST)

Thousands march against nuclear power in Tokyo

TOKYO (AP) -- Several thousand people are marching in downtown Tokyo calling on the government to abandon nuclear energy in the wake of the Fukushima nuclear accident.

The demonstrators chanted "Sayonara nuclear power" while holding banners and placards as they marched Monday, a national holiday in Japan.

Police gave an initial estimate that just over 20,000 people participated, but protest organizers put the figure at 60,000.

Either way, it is one of the biggest demonstrations since the March 11 accident, in which the tsunami-damaged Fukushima Dai-ichi power plant spewed radiation into the air in the worst nuclear disaster since Chernobyl.

(Mainichi Japan) September 19, 2011

Density of cesium over Fukushima plant's No. 2 reactor declines sharply

The density of cesium and other radioactive materials in the air over the Fukushima No. 1 nuclear plant's No. 2 reactor has dropped radically, Tokyo Electric Power Co. (TEPCO) said on Sept. 18.

Samples taken Sept. 17 from two openings at the top of the No.2 reactor building showed that the cesium density was one-10,000th to one-100,000th of a becquerel per cubic centimeter, a sharp decline from the end of August.

TEPCO said the density of cesium-134 and cesium-137 was less than one-100th of the permissible level and that of iodine-131 was below the detectable level.

Commenting on the drops in radioactive substance densities, TEPCO said, "The release (of radioactive substances) has been curtailed due to the ongoing cooling of the reactor, but wind outside the building may have influenced (the results)."

(Mainichi Japan) September 19, 2011

Largest antinuclear rally held in Tokyo since Fukushima crisis

TOKYO (Kyodo) -- Tens of thousands of people took to the streets in downtown Tokyo on Monday to call for the shutdown of all nuclear power plants in Japan, in the largest protest rally in the country since the Fukushima Daiichi plant catastrophe.

Nobel Prize-winning novelist Kenzaburo Oe, journalist Satoshi Kamata and actor Taro Yamamoto were among the speakers to address the crowd, which organizers put at 60,000 people. Tokyo police estimated the crowd at half that size, or 30,000 people.

"We need to let leaders of major parties and the Japan Business Federation know our intention to resist" nuclear power generation, Oe, a leading organizer of the event, told the gathering at Tokyo's Meiji Park.

Ruiko Muto, a 58-year-old activist who leads a movement to dismantle nuclear reactors in Fukushima Prefecture, delivered a more personal message.

"To escape or not to escape? To eat or not to eat? I was forced to make such choices every day" since the March earthquake and tsunami crippled the plant, said Muto.

The March 11 natural disasters knocked out all power supplies to the Fukushima Daiichi nuclear plant, leading to explosions that damaged three reactor buildings. The massive amount of radioactive material that escaped prompted the emergency evacuation of thousands of people living in surrounding communities, and concern about radioactive food contamination.

Muto urged people not to forget that a nuclear power plant is behind any power outlet.

"Each of us has to decide and act in order to achieve a life at the opposite extreme of nuclear power generation."

Yamamoto as a guest speaker said, "We already have sufficient electricity (even without nuclear plants). If we do nothing now, Japan will be a disposal site of nuclear waste."

Later participants split into three groups and marched in Tokyo, including through the fashionable district of Omotesando to protest against nuclear power generation.

Japan vows at IAEA confab to stabilize Fukushima Daiichi by year-end

VIENNA (Kyodo) -- Japan pledged Monday to move up the deadline for bringing the crippled Fukushima Daiichi nuclear power plant to a stable condition, telling an International Atomic Energy Agency conference it will do so by year-end.

Goshi Hosono, Japan's minister in charge of the nuclear accident, revealed the revised schedule at the annual conference of the U.N. nuclear watchdog. Japan previously said it would bring the plant to a condition known as "cold shutdown" by mid-January.

"We will move up the existing target period, and endeavor to achieve this 'cold shutdown' by the end of this year," Hosono said.

Hosono made the promise as the government and Tokyo Electric Power Co., the operator of the Fukushima plant, plan to update the current timeline Tuesday.

Hosono also said that the Japanese government is working to set up a Nuclear Safety and Security Agency in next April as an external body of the Environment Ministry to fully achieve "separation of authorities for regulation and promotion" of nuclear power.

Japan will subsequently accept an IAEA team sent to assess how effectively the new entity will function, Hosono said.

The IAEA began a five-day conference on Monday convened to endorse an action plan that its board of governors adopted last week and meant to enhance global nuclear safety in the aftermath of the Fukushima disaster. The conference will also discuss a draft resolution on the scrapping of North Korea's nuclear programs.

On the sidelines of the conference, Hosono said in a meeting with IAEA chief Yukiya Amano that he agreed that Japan will accept a team of IAEA experts in October sent to advise on decontaminating areas near the radiation-leaking Fukushima plant.

Japan also agreed to seek the agency's assistance in assessing safety measures related to the restart of atomic power plants in Japan currently shut down for regular checkups, Hosono said.

(Mainichi Japan) September 20, 2011

Hosono: Cooling down to be achieved this year

Japan's minister in charge of the nuclear disaster says reactors at the troubled Fukushima Daiichi plant will be cooled to below 100 degrees Celsius within this year.

Goshi Hosono spoke at the International Atomic Energy Agency's annual ministerial meeting on Monday.

He thanked the international community for assisting Japan in dealing with the accident at Fukushima.

Hosono said that decontaminated water has been successfully used to cool down the troubled nuclear reactors, bringing the temperature close to 100 degrees Celsius. He also said spent nuclear fuel pools have been cooled in a stable manner.

Hosono also said the spent nuclear fuel has been steadily cooled and will fall below 100 degrees by the end of this year, instead of early next year as initially predicted.

When the reactors and spent fuel have been cooled below 100 degrees, radiation emissions can be kept very low.

The minister also said Japan will work with the IAEA to remove radioactive materials from areas near Fukushima Daiichi.

He explained the plan to separate the Nuclear and Industrial Safety Agency from the Economy, Trade and Industry Ministry, saying it will be merged with the Cabinet Office's Nuclear Safety Commission to create a nuclear safety agency under the Environment Ministry by next April.

Tuesday, September 20, 2011 07:00 +0900 (JST)

Hosono seeks US, French help to scrap reactors

Japan's cabinet minister in charge of the nuclear disaster has asked the United States and France for help in scrapping the reactors at the Fukushima Daiichi power plant.

Goshi Hosono on Monday held separate meetings with US Nuclear Regulatory Commission Chairman Gregory Jaczko, US Energy Secretary Steven Chu and French Industry Minister Eric Besson in Vienna. They are in the Austrian capital for the general assembly of the International Atomic Energy Agency.

Hosono told the officials that the Japanese government is aiming for a cold shutdown of the Fukushima plant before the end of the year.

The government's plan to stabilize the plant originally called for achieving a cold shutdown early next year.

Hosono asked the US and French officials to help with essential work after the cold shutdown,

including scrapping the reactors, decontaminating soil and disposing of radioactive waste.

The officials responded positively.

Tuesday, September 20, 2011 07:00 +0900 (JST)

IAEA to send experts to Japan

The International Atomic Energy Agency says it will send experts to Japan to cooperate in the removal of radioactive materials in Fukushima Prefecture.

IAEA chief Yukiya Amano made the remarks on Monday in Vienna. He was responding to a request from Japan's nuclear crisis minister, Goshi Hosono.

Hosono said Japan needs international experience and expertise in order to make progress in the removal of radioactive materials in areas near the Fukushima Daiichi nuclear plant.

He also asked the IAEA for advice regarding stress tests for nuclear reactors in preparation for their restart after checkups. Amano said the agency will help.

After the meeting, Hosono said Japan is removing radioactive materials on a scale that no country has ever experienced.

He went on to say his country will seek advice from the IAEA on how to win public support for the restart of its safety-checked nuclear plants until its new nuclear safety agency is established.

Tuesday, September 20, 2011 07:00 +0900 (JST)

Groundwater flowing into Fukushima nuclear plant

TOKYO (Kyodo) -- Tokyo Electric Power Co. said Tuesday it suspects that 200 to 500 tons a day of groundwater might be flowing through pits and wall cracks into reactor and turbine buildings at the Fukushima Daiichi nuclear plant crippled by the March 11 earthquake and tsunami.

The suspicion is based on the fact that a decline in water levels in these buildings has slowed down.

"The suspected groundwater inflow is now unlikely to cause problems as the plant is capable of treating nearly 1,000 tons of radiation-contaminated water," said an official at the company known as TEPCO.

But the inflow is expected to affect efforts to contain the Fukushima nuclear crisis. "We should assess the groundwater inflow and readjust an overall plan for treating contaminated water," said an official of the Nuclear and Industrial Safety Agency at the Ministry of Economy, Trade and Industry.

(Mainichi Japan) September 20, 2011

TEPCO:Groundwater may be flowing into plant

The Tokyo Electric Power Company, or TEPCO, says a large amount of groundwater may be entering the crippled Fukushima Daiichi nuclear power plant.

TEPCO says it has found that 200 to 500 tons of what is probably rainwater that seeped into soil may be entering daily through cracks in walls into the basements of buildings housing reactors and turbines.

The utility says it's worried that this will increase the amount of highly radioactive water in the basements.

Workers at the plant are injecting about 550 tons of water a day to cool 3 of its damaged reactors. About 80,000 tons of highly radioactive water has already accumulated in the buildings.

TEPCO says it plans to keep levels of radioactive water lower than those of groundwater to stop further inflows.

The government's Nuclear Safety Agency says groundwater inflow must be considered in drawing up a long-term decontamination plan.

Tuesday, September 20, 2011 17:31 +0900 (JST)

A new plan set to reduce radiation emissions

The Japanese government and the operator of the troubled Fukushima Daiichi nuclear plant say they will install new devices to reduce the amount of radioactive substances released into the air.

The government and Tokyo Electric Power Company, TEPCO, originally planned to achieve a cold shutdown, in which temperatures of the reactors reach below 100 degrees Celsius by January next year.

They now say that they will aim to reach that status within this year, as their work is making steady progress.

The government and TEPCO revealed the plan in their monthly review of the timetable for containing the nuclear crisis.

They will install new devices at the NO.1, No.2 and No.3 reactors to take contaminated gases out of the reactors using filters. They plan to start installing the devices next week.

TEPCO also plans to complete the construction of a giant polyester shield over the No.1 reactor by mid-October.

The operator also plans to improve its cooling systems so that the temperatures of all 3 reactors will drop below 100 degrees Celsius.

They say the amount of radioactive substances released from the plant was about 200-million becquerels per hour in the first half of September. They say that's about one-four millionths of the level of the initial stages of the accident in March.

Tuesday, September 20, 2011 20:02 +0900 (JST)

65 percent of Japanese prefer to cut electricity use even if living standards drop

(Mainichi Japan) September 20, 2011 -

<http://mdn.mainichi.jp/mdnnews/news/20110920p2a00m0na017000c.html>

Sixty-five percent of Japanese people think that they should reduce their use of electricity even if their living standards have to be lowered in the wake of the outbreak of the crisis at the Fukushima No. 1 Nuclear Power Plant, according to a recent survey conducted by the Mainichi Shimbun.

A survey of 2,413 people, conducted in an interview format by the Mainichi from Sept. 2 to 4, shows 65 percent of the respondents prefer to cut electricity use even if they have to lower their standards of living. The survey did not cover people in Iwate, Miyagi and Fukushima prefectures hit hard by the March 11 disasters. Thirty-two percent of the people polled said power supply should be increased in order to maintain their standard of living.

The survey also shows that most people want to see nuclear power being phased out, with 60 percent of the respondents preferring to gradually reduce the number of nuclear reactors while halting the operations of high-risk reactors.

By gender, 60 percent of male respondents and 70 percent of female respondents said the use of electricity should be reduced even if the standards of living have to be lowered. By age groups, relatively young people tend to think the use of electricity should be cut at the expense of living standards, with 71 percent of those in their 30s and 67 percent of those in their 20s sharing such views. Of those respondents who put priority on cutting electricity consumption rather than on maintaining current living standards, 66 percent of them said the number of nuclear reactors should be gradually reduced.

On the question of what should be done to the nuclear reactors in the future, 60 percent of those surveyed said the number of reactors should be reduced gradually, while 20 percent said the nuclear reactors should be operated without increasing the number of reactors. Twelve percent of the respondents said all reactors should be stopped as soon as possible, while 6 percent said the existing reactors should be operated and new reactors should be built. The survey shows 70 percent of people seeking an end to the country's reliance on nuclear power generation.

On a plan to have a backup of Tokyo's capital functions to prepare for large-scale natural disasters, only 10 percent of the respondents said no backup would be necessary, while 43 percent said a backup should be created in Kansai, followed by 18 percent for Kanto outside of the metropolitan area and 9 percent for Tokai.

Because of the widespread impact of the Great East Japan Earthquake, many people prefer to have a backup of the capital's functions in Kansai rather than in Kanto and Tokai. Osaka Gov. Toru Hashimoto told Tokyo Gov. Shintaro Ishihara in July that he would try to make Osaka a backup for Tokyo's capital functions.

Noda voices confidence over resolution of Fukushima nuclear crisis

NEW YORK (Kyodo) -- Japanese Prime Minister Yoshihiko Noda on Thursday expressed confidence that the ongoing nuclear crisis at the Fukushima Daiichi power plant will be brought under control in the not-too-distant future.

In a speech at the United Nations, Noda pledged that Japan will disclose all information related to the crisis, the worst since the Chernobyl disaster in 1986, and share with the international community the lessons Japan has learned about nuclear safety.

Noda explained that he had visited the power plant, crippled by the March 11 earthquake and tsunami, earlier this month to get a closer look at its reactor buildings.

"This very fact demonstrates the steady progress in our efforts to bring the accident under stable control," he told the world body's high-level meeting on nuclear safety and security.

The prime minister informed U.N. Secretary General Ban Ki Moon and other world leaders of the latest Japanese estimates showing that the amount of radioactive substances being released from the reactors has fallen to around one-four millionth of the level at the early stage of the crisis.

Noda, who took office three weeks ago, said Japan will aim to bring the reactors into a state of cold shutdown by the end of this year, one month ahead of the initial target.

While admitting Japan's emergency response and preparedness for an enormous tsunami was insufficient, he said, "Japan is determined to raise the safety of its nuclear power generation to the highest level in the world," signaling that his government has no immediate plans to phase out the country's nuclear reactors.

Noda also said Japan stands ready to continue to export its technology and expertise to emerging economies seeking to introduce nuclear facilities and at the same time to step up its efforts to take the lead in expanding the use of renewable energy.

Noda, who is making his international debut as premier in New York, noted that Japan will present the specifics of its new energy policy over the medium and long terms around next summer.

He added that Japan will strengthen nuclear security with the rest of the world to prevent terrorist access.

In closing his remarks, Noda said he is confident Japan will overcome the nuclear crisis and there will be a time when Fukushima will be remembered as "the place where, through people's strong will and courage, a new era was opened for the future of humankind."

The high-level meeting, organized at the request of the U.N. chief in the wake of the Fukushima crisis, was attended by world leaders including Brazilian President Dilma Rousseff, French President Nicolas Sarkozy and South Korean President Lee Myung Bak, as well as top officials from more than 50 countries.

Many of them proposed that global nuclear safety standards be enhanced in conjunction with the International Atomic Energy Agency.

"Participants affirmed that the responsibility for ensuring the application of the highest standards of nuclear safety...lies with each state and operating organization," the U.N. chief said in his chairman's summary.

Nassir Abdulaziz Al-Nasser, president of the 66th U.N. General Assembly, said the Fukushima disaster was "a loud global wake-up call."

"When one of the world's best-prepared countries can experience such a large-scale nuclear accident, it is all too clear that we must continue to evolve our thinking and practices for the safe and secure operation of nuclear facilities worldwide," Al-Nasser said.

Still, many attendees at the same time said it would be unrealistic to abandon nuclear energy in the near future.

South Korean leader Lee said the Fukushima accident was "a hard blow" to trust in nuclear safety. But he said this should not be "cause to renounce nuclear energy. On the contrary, this is a moment to seek ways to promote the safe use of nuclear energy based on scientific evidence."

(Mainichi Japan) September 23, 2011

IAEA adopts action plan for nuclear safety

The International Atomic Energy Agency has unanimously endorsed an action plan on nuclear safety at its annual general conference in Vienna.

The plan calls for sending IAEA inspectors to member countries to evaluate the safety of nuclear plants at their request. It also requires the signatories to quickly organize a response team after a nuclear accident.

The plan was approved by the agency's 35-nation board last week -- six month since the nuclear crisis began at Japan's Fukushima Daiichi plant.

But the approval exposed differences on nuclear safety between the member states.

Some countries, including Germany, which has voted to scrap nuclear power, wanted the safety evaluation to be mandatory.

Others, such as the United States, insisted that it be voluntary. Ultimately, that view won the day.

The IAEA plans to implement the action plan swiftly, seeking cooperation from the member states.

Thursday, September 22, 2011 21:49 +0900 (JST)

UN to study implications of Fukushima accident

The United Nations says it will conduct a study on the implications of the Fukushima Daiichi nuclear power plant accident.

UN Secretary General Ban Ki-moon issued a chairman's summary after a high-level meeting on Nuclear Safety and Security in New York on Thursday.

About 60 heads of state and cabinet ministers took part in the talks including Japanese Prime Minister Yoshihiko Noda, French President Nicolas Sarkozy, and South Korean President Lee Myung-bak.

Ban said the Fukushima accident has raised concerns about international safety standards and emergency preparedness.

He said safety standards must be raised to the highest level possible, and urged member nations to review their nuclear power plants to make sure they can withstand serious natural disasters. He stressed the need for international cooperation to strengthen nuclear safety.

Ban noted that people near the Fukushima Daiichi plant are living in fear of the effects of radiation. He said the United Nations will survey their health.

Friday, September 23, 2011 14:20 +0900 (JST)

A Visit to J-Village

Fukushima Workers Risk Radiation to Feed Families

- By [Cordula Meyer](#)
- <http://www.spiegel.de/international/world/0,1518,786650,00.html>

Since the nuclear disaster at Fukushima, the power plant's operator TEPCO has relied on temporary workers to help bring the reactors under control. Many of the workers, whose radiation levels are measured daily, say they are not doing the work for Japan, but for the money. SPIEGEL visited J-Village, which is strictly off-limits, and met the unsung heroes of Fukushima.

Milepost 231 now marks the end of the road. Barricades prevent traffic from proceeding farther north on Highway 6, a four-lane road that leads to the ruin of the Fukushima Daiichi nuclear power plant. Men in uniform are waving stop signs. In the evening twilight, a red illuminated sign flashes the following message: "No access... disaster law." Two policemen armed with red glow sticks vigorously turn away every lost driver.

Three of their colleagues are blocking the exit to the right. They yell at anyone approaching on foot.

A total of 20 officers guard this intersection, day and night. To the right of the road block, the highway leads to J-Village, a former training center for the Japanese national soccer team. Since March 11, Japan's largest soccer complex has been transformed into the base camp for Japan's peculiar heroes -- the workers who are trying to regain control of the crippled Fukushima Daiichi nuclear power plant.

More than 1,000 of these workers prepare themselves for their shifts here, day after day. The TEPCO power company, which is the operator of the stricken nuclear power plant, sponsored construction of the sports facility years ago. Since it has become the hub for the nuclear cleanup workers, though, the company has sealed off the area to the media and the general public.

Only buses and vans with a TEPCO authorization on the front windshield are allowed to pass. The vehicles shuttle workers to the reactors and back to J-Village. The heads of the exhausted men are visible through the buses' windows: Many of them have fallen asleep during the over 30-minute trip home.

In one of the buses that struggles up the hill to J-Village sits Hitoshi Sasaki, 51, wearing a white Tyvek suit. The construction worker started here three weeks ago. His job is to surface a road to the destroyed reactor. The job involves laying down steel struts that will make it possible to support a 600-ton crane, which will be used to pull a plastic protective cover over the ruins.

Standing in Line for Radiation Checks

Sasaki's first stop in J-Village is the gymnasium to the right of the main building. Long lines of workers wearing protective suits and masks march up to the building.

There are boxes at the entrance of the gym, and Sasaki pulls the plastic covers off of his shoes and places them in the first box. Then the respirator, the white protective suits made of synthetic paper and the gloves are each placed in additional boxes.

A number of workers trudge toward the gym; hardly anyone speaks. Some stumble when they have to stoop over to strip off the plastic covers from their shoes. Others rip off their suits with both hands, as if every tenth of a second counts before they can finally remove the hot and sweaty suits from their bodies. Then they stand in line for radiation checks.

Most workers wear only long-sleeved dark-blue underwear under the suits. Those who have to spend particularly long periods in the oppressive heat and humidity are also allowed to wear turquoise vests under their protective suits. These vests contain a coolant designed to protect the men from heat exhaustion. Several workers have already collapsed. In August alone, 13 were admitted to an emergency room set up in front of reactors 5 and 6. A 60-year-old worker died in May, presumably of a heart attack.

A team of workers who have been quickly trained in radiation levels checks each man's exposure.

The inspectors are wearing protective suits, blue caps and paper masks. Under the basketball hoop at the end of the gym, folding tables have been set up with four mobile Geiger counters, and next to these are three permanently installed radiometers.

The inspectors are holding bulky instruments and gazing at the gauges. They move the sensors first over the head of each worker, then left and right along the arms, chest, abdomen and legs. During the check, the workers stand on a mat with an adhesive film designed to capture radioactive particles. Many of the men are young and look as if they are in their early twenties, but a number of weary old men are also among them.

Temporary Workers Doing the Dirty Work

One of the workers feels that the public has a right to know what is happening in J-Village. He has decided to speak with SPIEGEL, although he would prefer not to give his name. He will be referred to as Sakuro Akimoto here. On busy days, he says, more than 3,000 workers pass through the radiation detection station.

Every day a brigade is deployed to the Fukushima Daiichi nuclear power plant in an attempt to bring the stricken reactor under control. The workers toil in sweltering heat and dangerously high radiation levels. The maximum annual dose for workers in Japanese nuclear power plants is normally 50 millisievert. After consulting with the authorities, TEPCO has decided to raise the maximum allowed dose to 250 millisievert, high enough to significantly increase the likelihood of developing cancer.

Some 18,000 workers have helped manage the disaster since March 11. Most of them are not employed by TEPCO, but by subcontractors, who in turn recruit their workers from temporary employment agencies. Before the tsunami, many of these temporary workers had already done their fair share of the dirty work at other nuclear power plants.

Most of them are not doing this to save Japan, but to feed their families. Sasaki, the construction worker, has also come for the money. He was approached by a company from Hokkaido in northern Japan where he lives. As a young man, he had helped with major overhauls at other power plants.

Each morning, says Sasaki, he dons his suit and mask in J-Village, and makes a second stop behind the plant's gates. Here he has to put on a lead vest, and over this an additional protective suit made of especially thick material, safety glasses, a mask that covers his entire face, and three different pairs of gloves, one on top of the other. "It is so unbearably hot," says Sasaki. "I feel like pulling the mask right off my face, but that's not allowed anywhere." Nonetheless, there are reports of workers who take off their masks, sometimes to smoke a cigarette.

'It Looks Much Worse There Than on TV'

There are meetings in the morning where every worker finds out what he is doing that day, after which the buses head off to the reactor. Sasaki is only allowed to work one hour per day, or at most 90 minutes, otherwise he will receive an excessively high dose of radiation. Then he heads back to J-Village, and on to his boarding house in Iwaki- Yumoto, where he shares a room with three men. Days like this have him on the go for six hours.

Sasaki is a small but muscular man. His arm muscles ripple under his black T-shirt.

He vividly remembers how he saw the destroyed reactor for the first time in mid-August. "It looks much worse there than on TV," he says. "Like New York after September 11. Destruction everywhere." He hasn't told his family that he works at the plant. He doesn't want them to worry.

He has his own worries. He needs the money, which is just under €100 a day. But if things keep going like this, he says that he will only be able to do the job a few more weeks until he reaches his company's radiation limits.

Workers Pushed to Their Limits

TEPCO is preparing to spend decades in J-Village. Workers have spread gravel around the large soccer stadium and in a number of adjacent areas. Here they have placed row after row of gray trailers. There are 40 per row and they sit two stories high, extending right up to the blue plastic seats in the stands.

The stadium's large scoreboard still hangs behind this makeshift community. The stadium clock has stopped at 2:46 p.m., which was the moment when the earthquake cut off the electricity here and at the power plant 20 kilometers (12 miles) away. Now, the power is on again and white neon lights illuminate the rows of trailers.

In one room the workers can pick up bento boxes. Next door TEPCO has built a laundromat with more than a hundred washing machines. Behind the main building in J-Village, buses are parked on the former soccer fields and debris is stored in large plastic bags on the tartan track.

Stacks of Contaminated Suits

In the courtyard of the main building, TEPCO has had a small store built, where workers can purchase cigarettes and tea. Some of them, still wearing their work overalls, have gathered around a number of ashtrays and are smoking in silence.

There is an Adidas advertisement glued to one of the doors and an obsolete warning sign: "No SPIKES!" An exhausted worker is asleep on the floor in the hallway.

In the window of the atrium hang huge banners for TEPCO Mareeze, the soccer team that belongs to the energy company. In the center of the building stands a panel with a large white and green map of J-Village. There was a time when this was there to help athletes find their way around. Now, a man in a TEPCO uniform stands here and uses a red felt pen to post the current radiation levels for over a dozen different places on the premises.

Three TEPCO employees are sitting nearby with their laptops. The workers hand them their daily dosimeters. In return, they are given a receipt that resembles a cash register sales slip and shows the dose of radiation that they have received that day.

In the corridors hang large framed photographs of famous moments in soccer history.

One of them shows German goalkeeper Manuel Neuer during the match between Germany and England at the 2010 World Cup. Outside on the covered playing field, eight goal posts have been

pushed aside and are nestled together. Workers' underwear has been hung out to dry on one of the crossbars.

At the entrance someone has used pink tape to attach a sign to the bare concrete: "Caution! Contaminated material." Behind this sign, used protective suits and masks are stacked in piles that are 4 to 5 meters high.

Three Shifts Around the Clock

A stooped-over man in a white and blue uniform leads the way to the far corner, where radioactive dirt is lying in a kind of rubber pool. The man says the dirt was washed off cars that had been close to the reactor. Nearby, someone has taped markers to the artificial turf, much like the ones that runners use to gauge their run-ups. Here, however, workers have written radiation levels on the tape. With every meter that you approach the pool, the radiation levels increase: 4.5 microsievert, 7.0 and then, finally, one meter away: 20 microsievert.

The men from the radiation detection team bring new bags full of refuse from the gym out onto this field every few minutes. The work here at J-Village is less dangerous than at the reactor.

"There are two types of jobs," says Sakuro Akimoto. "Either you work in J-Village for many hours with less radiation or in Daiichi for fewer hours, but at radiation levels that are 10 to 100 times higher." Akimoto is tall and wiry. He wears his hair short and loves casual jeans. He started working 30 years ago, right after leaving school, for a company that does maintenance work for TEPCO.

There are hardly any other jobs in the village where he comes from, which is located near the power plant. On March 11, he was working at the plant and was able to flee in time to escape the tsunami. His village was evacuated. A few weeks later, he says, he received the order to come to J-Village, "whether I wanted to or not." But he says he also felt a sense of responsibility because the plant had brought so many jobs to the region.

The members of the radiation detection team are now working in three shifts around the clock. He has often seen workers "at their limit -- not only physically, but also mentally."

Most jobs are simply dirty work, he says. According to Akimoto, many of his co-workers who work for subcontractors had no choice but to come here. "If they refuse, where will they get another job?" he asks. "I don't know anyone who is doing this for Japan. Most of them need the money." Whenever possible, highly qualified workers like Akimoto are only exposed to comparatively low levels of radiation. After all, they will be needed later.

A Move to Raise Radiation Thresholds

In an internal paper, Japan's nuclear safety agency NISA warns that there will soon be a lack of technicians because too many have exceeded their radiation limits. As early as next year, NISA anticipates that there will be a shortage of 1,000 to 1,200 qualified workers, "which will severely affect the work at Fukushima Daiichi and at nuclear power plants throughout the country."

The nuclear safety agency's solution is simple: create higher thresholds. It recommends raising the limits to allow workers to be exposed within a few years to significantly greater amounts of radiation than before.

By mid-August, 17,561 men had been registered at the Health Ministry as radiation workers. There are plans to monitor their health in a future study. Six of them have been exposed to radiation levels exceeding the high limit of 250 millisievert. More than 400 people have been exposed to levels exceeding the normally allowed 50 millisievert.

And TEPCO simply does not know about some of its workers. Despite months of searching, the company can no longer locate 88 workers who were employed in the power plant from March to June. The company had merely handed out badges to contractors without meeting the workers in person. Worker IDs with barcodes and photos have only recently been introduced.

Earning €100 Per Day

Hiroyuki Watanabe is a city council member from Iwaki, the city that lies to the south of J-Village. For the past two years, he has been trying to determine where TEPCO recruits its workers. "The structure is dodgy," says Watanabe. "It is amazing that one of Japan's largest companies pursues such business practices."

In fact, TEPCO has been using shadowy practices to acquire its workers for a number of years. In 2008, Toshiro Kitamura from the Japan Atomic Industrial Forum criticized the Japanese power company for "outsourcing most of its maintenance work of nuclear power plants to multi-layered contractors." The industry expert's main concern, however, was the safety risk, since these workers are not as familiar with the reactors as permanent employees.

According to Watanabe, TEPCO has budgeted up to €1,000 per person per day to pay the workers. But unskilled workers, he says, often receive only about €100 of that money. "These are men who are poor or old, with no steady job and limited employment opportunities," he says. Some of them don't even have a written employment contract, he contends. When they reach their radiation exposure limit, he adds, they lose their jobs and the employment agency finds a replacement.

Watanabe wants to ensure that all workers are paid appropriately. Even the lowest ranking workers should have a trade union, he says. "If we have a problem, we have nobody to turn to," says a young worker who is eating dinner along with seven co-workers at the Hazu restaurant in Iwaki-Yumoto. They are drinking beer and sake with their meal and smoking countless cigarettes. The men actually don't want to talk about the power plant -- but they go ahead and do it anyway. They also talk about their families and the fear of the radiation and its consequences.

'Somebody Has To Do It'

Next door in the laundromat, 24-year-old Yutaka is stuffing his socks and T-shirts into a washing machine. He is wearing plaid shorts and a polo shirt with a matching collar. Every night in his boarding house room, he calculates his current level of radiation exposure.

"To be honest, it makes my wife worried," he says. He has no intention of quitting, however. "Somebody has to do it," he says. Yutaka is in charge of the break room. His wife has been living far from here ever since they were evacuated. "I don't know if we will ever be able to return," he says.

The presence of so many workers has fundamentally changed Iwaki-Yumoto. This small town on the southern edge of the exclusion zone was known for its hot springs, which attracted large numbers of tourists. Now, there are no more tourists, and many residents have also fled. The hot springs are still very popular, though now it is with the workers. Between 1,000 and 2,000 of them live here now, says a hotel owner in the city. There are plans to move many of them soon to new trailers on the playing fields of J-Village.

One of the workers in Iwaki-Yumoto comes from the now-abandoned village of Tomioka in the restricted area. He smokes Marlboro menthols, and his arms and legs are covered with tattoos. During the day, he works in front of reactor 4, assembling plastic tubes for the decontamination system.

The hardest thing for him, he says, is the daily trip to work. The bus drives past his house twice a day, passing directly in front of the bar where he used to play pachinko, a Japanese game similar to pinball.

"I feel sad when I see it all so empty," he says. He says he dreams of returning there some day to play pachinko again.

Translated from the German by Paul Cohen

Fukushima finds cesium in Nihonmatsu rice, to hold more tests before shipment decision

The Fukushima Prefectural Government said on Sept. 23 that it had detected 500 becquerels of radioactive cesium per kilogram -- the government-set allowable limit -- in a sample of "Hitomebore" rice collected in Nihonmatsu's Obama district. It will greatly increase the number of testing locations there for a second test to decide whether to allow shipments of rice from the city.

After discovering radioactive cesium in the rice crop from the city, Nihonmatsu became the first area to be designated a "priority test area," which means the local government will increase the number of locations in the city where rice crops are tested for radioactive substances before deciding whether to allow shipments.

Early-season rice from across Fukushima Prefecture was already previously approved for shipments, and some municipalities have started shipping their regular season rice. The test results from Nihonmatsu have again stirred worries among farmers and others about effects on Fukushima products' reputation.

According to the prefectural government, 500 becquerels of radioactive cesium were detected in a rice sample collected on Sept. 12, and soil in its paddy field contained 3,000 becquerels of cesium per kilogram. Rice crops from 11 other locations in the Obama district had from undetectable amounts up to 212 becquerels of cesium.

Preliminary tests such as the one that found the problem rice in Nihonmatsu are being conducted about one week before harvesting in 370 zones covering the whole prefecture. Those municipalities where rice with 200 becquerels or more of cesium are found are designated as "priority test areas." Such areas get two testing locations per 15 hectares of land for a later second test that determines whether shipments from the zone will be allowed.

Following the Nihonmatsu test results, the Fukushima Prefectural Government plans to increase the number of testing locations there from around 40 to around 300. If rice with 500 becquerels or more cesium per kilogram is again found, shipments of all rice crops from that part of the city will be restricted.

Before the Nihonmatsu finding, the highest level of cesium detected in ordinary rice from Fukushima Prefecture in preliminary tests was 136 becquerels in Fukushima city's Onami district.

The Ministry of Agriculture, Forestry and Fisheries estimated the transfer coefficient of cesium from soil to rice crops at 0.1 (10 percent) and banned planting rice in paddy fields with more than 5,000 becquerels of cesium per kilogram of soil. Based on these values, in theory rice from the prefecture should not contain more than 500 becquerels of cesium.

Hydrogen detected in pipe at Fukushima No. 1 reactor

The Yomiuri Shimbun - <http://www.yomiuri.co.jp/dy/national/T110923004917.htm>

Hydrogen has been detected in a pipe at the No. 1 reactor at the Fukushima No. 1 nuclear power plant, but there is no possibility it will cause an explosion "in the immediate future," the plant's operator said Friday.

According to Tokyo Electric Power Co., hydrogen of at least 10,000 parts per million was detected at two spots in a pipe passing through the containment vessel on the reactor building's first floor. This concentration was higher than TEPCO had anticipated.

Although TEPCO is not certain how much hydrogen is still inside the vessel, the utility believes **it is possible the concentration of the highly flammable gas is higher than had been assumed.**

In air and liquid, 10,000 ppm is equivalent to 1 percent. Air containing at least 4 percent hydrogen and 5 percent oxygen is at risk of causing explosion.

TEPCO has been injecting nitrogen into the containment vessel since April so **it is assumed there is virtually no oxygen.** As a result, the utility ruled out the possibility of an explosion "in the immediate future."

The hydrogen was detected during an examination of the pipe before installation of a radioactive gas purification system inside the containment vessel. TEPCO said it had closely examined the hydrogen concentration and **would inject nitrogen into the pipe to flush out the remaining hydrogen.**

TEPCO said it had expected hydrogen would still be inside the containment vessel, but that it would have no effect on the radioactive gas purification system.

The nuclear plant's Nos. 1, 3 and 4 reactors were damaged by hydrogen explosions in the days after the March 11 earthquake and tsunami knocked out the plant's cooling systems.

Noda changing Kan's N-plant stance

The Yomiuri Shimbun

Prime Minister Yoshihiko Noda is slowly changing the government's stance on nuclear power generation, which his predecessor, Naoto Kan, wanted to replace with other energy sources.

In July, when he was prime minister, Kan revised the long-held Japanese policy of promoting nuclear power and exports of nuclear technology because of the crisis at Tokyo Electric Power Co.'s Fukushima No. 1 nuclear power plant.

Noda seems to be taking a more moderate approach by insisting that a stable electric power supply utilizing nuclear power plants is essential for economic growth.

In his opinion, both economic growth and fiscal health are inseparable for rebuilding the economy.

At a high-level U.N. meeting in New York on nuclear safety and security Thursday, Noda said: "For several years, emerging nations and many other countries around the world have earnestly explored ways of using nuclear energy amid the need for energy security and in response to global warming. Japan supported their efforts and remains steadfast in responding positively to their interest in our undertakings."

This indicated that the prime minister was committed to continuing Japan's policy of exporting nuclear power plant equipment and technology.

In an interview with the Wall Street Journal on Tuesday ahead of his visit to the United States, Noda clearly mentioned the timing for reactivating nuclear reactors idled for regular checkups.

Though Noda said the "biggest precondition" was winning the understanding of prefectures where nuclear power plants are located and confirming the safety of the plants, he emphasized, "From spring through summer next year, we must bring them [the reactors] back online as best as we can." He also indicated nuclear power plants now under construction would eventually go online.

Since becoming prime minister, Noda has announced one policy after another.

A government source said this was because Noda wanted "to clearly show other countries that his policies were different from those of the Kan administration."

The prime minister believes that to revitalize the Japanese economy and achieve fiscal health, Japan must secure a stable electric power supply by utilizing nuclear power plants, the source said.

In his first policy speech to the Diet as the prime minister on Sept. 13, Noda said he would compile a new energy strategy, including the use of nuclear power, by summer.

However, political analysts said Noda so far had yet to draw up a long-term energy strategy.

The prime minister pledged in the Diet to "lower reliance on nuclear power plants as much as possible," indicating he would reduce reliance on nuclear power.

Though he drew a clear line between his and Kan's policy, Noda's remarks about the construction of new nuclear power plants or reactors have been ambiguous.

At one point, Noda suggested the number of reactors in service would be zero within a few decades. But on another occasion, he hinted that the construction of new reactors would be possible depending on the situation.

Fukushima municipality heads concerned over lifting of evacuation advisory

FUKUSHIMA (Kyodo) -- Heads of five municipalities in Fukushima Prefecture affected by the ongoing nuclear crisis have aired concerns over the government's plan to lift its evacuation advisory in the event of an emergency, saying **not enough has been done to ensure the safety of residents.**

In recent interviews with Kyodo News, the chiefs of the five local governments said they were especially worried about the cleanup of radioactive substances released from the crippled Fukushima Daiichi plant and the disposal of radioactive waste. The Fukushima Daiichi plant, the source of the worst nuclear disaster since Chernobyl, suffered massive damage due to the March 11 earthquake and tsunami.

The advisory covers the entire town of Hirono and parts of Naraha, the village of Kawauchi, and the cities of Tamura and Minamisoma, where roughly 59,000 residents have been told to be prepared to evacuate or remain indoors in the event of an emergency. About 25,000 have evacuated.

The areas are in a ring located 20-30 kilometers from the crisis-hit nuclear plant. Children, pregnant women and people who need medical support have been advised to evacuate, and schools and kindergartens there are closed based on the government advisory issued on April 22.

In August, the central government said it would lift the evacuation advisory in the near future, saying there is only a slight risk of cooling system failures at the nuclear plant and radiation exposure levels are very low in the area.

The government is set to lift the advisory by the end of September as the five municipalities have submitted recovery plans which spell out details of decontaminating their areas and rebuilding basic infrastructure.

The municipal governments of Kawauchi and Tamura said they are planning to allow residents to return to their homes next March, while Hirono said it would do so by the end of 2012.

Minamisoma, whose residents account for some 80 percent of the 59,000 residents covered by the advisory, asked its citizens in July to return to the city by the end of August and has not issued instructions since then.

Naraha said it would ask residents to return home when the central government abolishes the 20-kilometer no-go zone around the nuclear plant.

In an interview, **Hirono Mayor Motohoshi Yamada criticized the central government for lifting the advisory before implementing steps to thoroughly decontaminate radiation-contaminated areas.**

"We will not allow our residents to return home unless their safety is secured. We are also concerned about how to finance the cost of the decontamination work," Yamada said.

Minamisoma Mayor Katsunobu Sakurai said the city began clean-up activities in August, but has found it difficult to decontaminate mountains, farmlands and rivers.

"There are no benchmark figures to refer to in our efforts to lower radiation and reassure our residents. We will proactively release information so that they can judge themselves whether to return home," Sakurai said.

Tamura Mayor Yukei Tomitsuka urged the central government to clarify the target amounts for radiation decontamination because the city lacks the expertise to do so itself.

Kawauchi Mayor Yuko Endo said villagers are uneasy as they do not know how long the decontamination process will continue and radioactive waste will remain.

Naraha Mayor Takashi Kusano said the town will not urge its residents to return home even after the government lifts the evacuation advisory because most of the residential areas fall in the 20-km no-entry zone. He said the city will give priority to the decontamination of industrial areas so companies can resume operating.

Residents near Fukushima nuclear plant make own radiation map, clean contaminated areas

A map, created as an initiative of the Ota district residents' council, shows radiation levels within the district in Minamisoma, Fukushima Prefecture. (Mainichi)

MINAMISOMA, Fukushima -- Residents in this city, some areas of which fall within the 20-kilometer no-entry zone from the crippled Fukushima No. 1 nuclear plant, have organized a council to measure radiation levels and remove radioactive material spread from the power plant.

The council has also published a radiation map that is twice as precise as the one released by the government, making it the most up-to-date and detailed radiation map available for the area.

In the beginning of July, residents from the Ota region in the Haramachi Ward in the city of Minamisoma, gathered to organize the 'Ota area reconstruction council,' the activities of which involve measuring radiation levels within the area and decontaminating public roads.

"We can't keep on relying only on the government," Kisao Watanabe, 70, the chairman of the council, said. "We decided to do what we could by ourselves, hoping we can return to normal life as soon as possible."

After inviting nuclear experts to teach them how to use radiation measuring devices -- which they purchased with a 500,000-yen subsidy from the local government -- the members spent two weeks from July 13 through July 30, dividing themselves into groups of two to three, to inspect various locations within the region. With the help of a GPS (global positioning system) and four measuring instruments, they inspected radiation levels at a total of 470 locations within the Ota district.

Based on the results of their findings, the council completed a map on Sept. 2, which displays radiation levels within the district, **given for one centimeter and one meter aboveground for all 470 locations, one location for every 200 meters.**

The map is the most up-to-date and detailed one currently available, as the one issued by the government -- also in September -- shows radiation levels in the areas around the Fukushima No. 1 Nuclear Power Plant at one location for every 500 meters.

On Sept. 15 council members distributed the map to all 1,000 households in the area.

According to the council's map, radiation levels in all inspected locations were measured at 0.25 to 4.62 microsieverts, but with the exception of mountains and forests in the western part of the prefecture, radiation was comparatively low.

Meanwhile, on Aug. 28, 90 council members decontaminated approximately 800 meters of sidewalks along the ward's main public roads in another initiative to speed up the city's recovery.

"It is very sad indeed," Watanabe said, referring to the fact that after the Fukushima disaster many schools in the city have closed and a number of families with small children have left. "All we want is to return to a normal life. We understood well that the government never had a disaster-preservation plan, despite building 54 nuclear power plants across the country," he added, vowing to continue the council's initiatives.

(Mainichi Japan) September 25, 2011

28 million cubic meters of 'hot' soil in Fukushima / Ministry aims to set storage site guidelines

The Yomiuri Shimbun

Up to 28 million cubic meters of soil contaminated by radioactive substances may have to be removed in Fukushima Prefecture, according to the Environment Ministry.

In a simulation, the ministry worked out nine patterns according to the rates of exposure to and decontamination of radioactive materials in soil, mainly in forests.

The ministry found if all the areas which were exposed to 5 millisieverts or more per year were to be decontaminated, 27.97 million cubic meters of contaminated soil would have to be removed. The calculation covered 13 percent of the prefecture's area.

These figures indicate the size of the temporary facilities that will be needed to store the soil, and the capacity of intermediate storage facilities where the soil will be taken later.

The assumptions were made using three categories according to yearly radiation doses in soil--20 millisieverts or more; 5 millisieverts or more; and 5 millisieverts or more plus some areas with contamination of from 1 to 5 millisieverts.

The three categories were divided further according to possible decontamination rates in forests--100 percent, 50 percent and 10 percent. The resulting nine patterns were broken down further to include "houses and gardens," "schools and child care centers" and "farmland."

The ministry calculated that the largest amount of contaminated soil was 28.08 million cubic meters in the case of 100 percent decontamination in forests in the category of 5 millisieverts or more plus some areas with contamination of from 1 to 5 millisieverts.

The smallest amount was 5.08 million cubic meters if 10 percent decontamination is carried out in forests with radiation doses of 20 millisieverts or more.

In the breakdown of areas with yearly radiation doses of 5 millisieverts or more, it was found 1.02 million cubic meters of soil should be removed from houses and gardens, 560,000 cubic meters from schools and child care centers and 17.42 million cubic meters from farmland.

The total amount of contaminated soil with a yearly radiation dose of 5 millisieverts or more is 27.97 million cubic meters in the case of 100 percent decontamination in forests that cover an area of 1,777 square kilometers.

The figures will be submitted Tuesday to a ministry study group that decides on the nation's decontamination policy.

The ministry made its calculation based on an aerial survey by the Education, Culture, Sports, Science and Technology Ministry and a land use survey by the Land, Infrastructure, Transport and Tourism Ministry.

A senior Environment Ministry official said, "The standard we basically agreed on at a study meeting is decontamination in areas with yearly radiation doses of 5 millisieverts or more."

Even though forests occupy about 70 percent of contaminated areas in the prefecture, the ministry does not believe it will be necessary to remove all contaminated soil, **as long as the government restricts the entry of residents in mountainous areas and recovers cut branches and fallen leaves, according to the official.**

The usual practice is to remove soil up to a depth of five centimeters. However, a senior official said this depends on the location of the contaminated soil.

The Environment Ministry will draw up plans based on a law concerning special measures on dealing with environmental contamination by radioactive substances as early as the end of November and start full-scale decontamination in January.

But the government still has not procured sufficient storage sites for contaminated soil, which has been temporarily buried in school yards or piled on vacant lots.

According to the central government, contaminated soil should be collected at temporary storage sites by local governments. The government recommends placing impermeable sheets under the soil at locations far from living areas.

The government also has no prospect of setting up intermediate storage facilities. Shortly before he stepped down, former Prime Minister Naoto Kan called on the Fukushima Gov. Yuhei Sato to set up facilities in the prefecture. The request was rejected.

Contaminated soil must be removed as soon as possible to allow evacuees to return to their houses within no-entry and evacuation zones.

(Sep. 26, 2011)

Hydrogen check ordered at No.2, 3 reactors

Japan's nuclear safety agency has instructed the operator of the stricken Fukushima Daiichi nuclear power plant to check if hydrogen is building up in its No.2 and 3 reactors.

This is after the Tokyo Electric Power Company, or TEPCO, recently detected hydrogen in a pipe leading to the containment vessel of No.1 reactor. A hydrogen explosion occurred at the No.1 reactor on March 12th, after the March 11th quake and tsunami.

The government's Nuclear and Industrial Safety Agency on Sunday instructed TEPCO to check pipes in the No.2 and No.3 reactors. The No.3 reactor suffered hydrogen explosion on March 14th and No. 2 reactor had a hydrogen explosion on March 15th.

The utility says it will measure the levels of hydrogen at the No.1 reactor before injecting nitrogen and taking other measures to prevent another explosion.

[on the 24th TEPCO said : "TEPCO said it had closely examined the hydrogen concentration and would inject nitrogen into the pipe to flush out the remaining hydrogen."]

The firm is expected to take similar measures if hydrogen is detected at the No.2 and No.3 reactors as well.

Makinohara assembly adopts resolution seeking Hamaoka nuclear plant's permanent halt

MAKINOHARA, Shizuoka -- The city assembly here on Sept. 26 adopted a resolution calling for a permanent halt to operation of the Hamaoka Nuclear Power Plant as long as its safety in the event of a major earthquake and tsunami cannot be guaranteed.

Makinohara, a city with a population of about 50,000 located within a radius of 10 kilometers from the suspended plant, is the first of five local governments with nuclear safety pacts with Chubu Electric Power Co. to call for a permanent end to the plant's operations.

Makinohara Mayor Shigeki Nishihara said during the assembly meeting, "There is a high probability of an inland Tokai earthquake, and we cannot give up our demand for a permanent halt."

Chubu Electric halted the plant's operations in May at the request of the central government. It plans to restart the plant after completing tsunami preparations such as an 18-meter-high breakwater and getting approval from local authorities.

The Makinohara assembly's resolution did not touch on the new tsunami preparations. It read in part, "In light of the serious accident at the Fukushima No. 1 Nuclear Power Plant, we must think foremost about protecting the lives and property of our citizens."

In a city-administered survey of Makinohara residents conducted in June and July, 60 percent of respondents said the Hamaoka plant should remain suspended. A separate survey conducted in May and June revealed that of 10 large companies with holdings in the city such as Suzuki Motor Corp., six were considering moving out of the city to minimize risks associated with an accident at the plant or a Tokai earthquake.

Chubu Electric's public relations group at its Shizuoka branch responded to the Makinohara assembly's resolution by saying, "We will steadily implement tsunami prevention measures and improve the plant's safety while doing our utmost to give complete explanations that will allow residents to feel secure."

(Mainichi Japan) September 26, 2011

Gov't to allow ash containing over 100,000 becquerels of cesium per kg to be buried

The Environment Ministry decided Sept. 25 to allow ash with radiation levels of more than 100,000 becquerels per kilogram to be buried **if steps to prevent leaks of radioactive substances are properly taken, [???** ministry officials said.

The ministry made the decision on contaminated ash following a similar decision on rubble contaminated with radioactive substances that spewed from the crippled Fukushima No. 1 Nuclear Power Plant after the March 11 Great East Japan Earthquake and tsunami.

From now on, ash with radiation levels of over 100,000 becquerels is required to be **solidified with cement and can be buried at facilities where measures are in place to prevent the seeping of rainwater and the leakage of contaminated ash to groundwater.**

The ministry is also considering utilizing existing permanent disposal sites that are surrounded by concrete walls to bury toxic heavy metals or those sites equipped with measures to stop such materials from leaking into groundwater.

Of a survey of about 650 industrial waste incineration plants in Tokyo, Fukushima and 14 other prefectures, the ministry checked the density of radioactive cesium at 110 of them and found ash with a radiation level of 144,200 becquerels of cesium per kilogram at one incineration plant in Fukushima.

(Mainichi Japan) September 26, 2011

Burying of radioactive household waste challenging

Japan's environment ministry says that the disposal of radioactive ashes from household garbage is not going well in Tokyo and surrounding areas, partly due to residents' objections.

Following the nuclear accident in Fukushima, waste facilities in the Tohoku, Kanto and Koshin-etsu regions showed that **ashes in garbage from private homes contained radioactive cesium**.

The ministry has set guidelines for disposing of the ashes. They say that if the level is 8,000 becquerels per kilogram or lower, the ashes can be buried. For ashes with cesium levels between 8,000 and 100,000 becquerels, the ministry says they must be deposited in cement and put in concrete vessels.

The ministry recently surveyed waste incineration facilities in the regions to see how the ash disposal is proceeding.

Of 410 facilities where cesium levels of ashes were 8,000 becquerels or lower, 22 sites mainly in the Tokyo Metropolitan area have been storing the ashes. They say they cannot bury the ashes due to residents' objections.

The survey also found ashes which had over 8,000 becquerels of cesium had not been buried at 42 facilities. They said that disposal was difficult.

The ministry plans to send officials to municipalities' meetings to explain to residents the safety of waste disposal. It also plans to demonstrate more specific ways of disposing of the highly contaminated ashes.

Monday, September 26, 2011 05:26 +0900 (JST)

Japan to freeze fast-breeder reactor project

Japan is likely to freeze a research and development project related to putting a fast-breeder nuclear reactor into practical use.

The education, science and technology ministry plans to request more than 20 billion yen, or about 260 million dollars, in its 2012 budget to maintain and manage the troubled prototype fast-breeder Monju reactor. This is roughly the same amount budgeted for the project as in the current fiscal year.

But the ministry is planning to ask for only 20 to 30 percent of the 10 billion yen, or about 130 million dollars, allocated in the current fiscal year for research and development on the project.

This is due to uncertainty over Japan's future nuclear policy in the wake of the accident in Fukushima.

Fast-breeder reactors run on recycled spent fuel as the core of a nuclear fuel-recycling program. Japan has been conducting research to put such a reactor to practical use by 2050. Test runs are now under way at the Monju experimental reactor in Tsuruga City, Fukui Prefecture.

Following the accident at the Fukushima Daiichi nuclear power plant, the government has been reviewing its basic energy plan, making its future nuclear policy unclear.

The ministry says it has concluded that it cannot proceed with the project when it is unclear which way the government's energy policy will go.

Monday, September 26, 2011 16:47 +0900 (JST)

Researchers to study effects of radiation on Fukushima marine life to rejuvenate fisheries

IWAKI, Fukushima -- Authorities here will study how radioactive cesium affects marine life in a bid to rejuvenate local fisheries in the wake of the Fukushima nuclear disaster.

The Fukushima prefectural fisheries experiment station in Iwaki will launch an experiment study in October on how fish and shellfish take in cesium and how long it will take to reduce the effects of cesium by keeping marine life in cesium-laced water tanks.

While coastal fishing in Fukushima has been suspended following the crisis at the Fukushima No. 1 Nuclear Power Plant and the ensuing release of radiation-contaminated water into the ocean, local authorities are seeking to find ways to secure the safety of marine life for the future recovery of Fukushima fisheries.

According to a survey by the prefectural fisheries experiment station that concluded on Sept. 12, levels of radioactive cesium exceeding the government's provisional safety limit of 500 becquerels per

kilogram have been detected in 18 out of 94 varieties of fish and shellfish caught along the coast off Fukushima.

However, the experiment station did not detect cesium in white bait in September even though it had detected 850 becquerels of cesium in the fish in May. Meanwhile, levels of cesium three times the provisional limit have been detected in some flatfish. It is unknown why the effect of cesium differs depending on fish species and even individual fish.

The fisheries experiment station is teaming up with the Fisheries Research Agency, an independent administrative institution based in Yokohama, to conduct the research. They have already started keeping red sea bream and will start keeping several other species including flatfish, abalone and sea urchin.

Researchers will keep uncontaminated fish and shellfish in radiation-contaminated water while keeping contaminated fish in uncontaminated seawater to study the relationship between the concentration of contamination in seawater and the degree of resultant contamination in fish and shellfish, as well as how long it will take to reduce radioactive contamination.

"Fukushima's fisheries have a long way to go to overcome harmful rumors. If we could reveal how radiation effects marine products, we can establish the means to secure seafood safety. We are committed to producing results that can help the recovery of local fisheries," said Satoshi Igarashi, head of the fisheries experiment station.

While offshore fishing was resumed in Fukushima Prefecture in June, coastal fishing has still been suspended out of fears for radiation contamination, with a blanket ban imposed on sea urchin and abalone fishing throughout the May-August harvest season. Trawl fishing has also been suspended even though its off-season is over, as has been gill net fishing that has no off season.

The prefecture's federation of fisheries cooperative associations decided on Sept. 22 that local fisheries will continue to refrain from operations through October. The federation, however, started looking into the possibility of resuming the fishing of octopus, squid and other species whose levels of cesium are within the safety limit -- on an experimental basis. The federation will double the number of sampling survey ships to two and equip fisheries cooperative associations with five radiation measurement devices.

Fukushima evacuation advisory to be lifted

The government will lift an evacuation advisory for 5 municipalities in Fukushima outside the 20-kilometer no-entry zone around the troubled Fukushima Daiichi nuclear power plant.

Senior Vice Minister of Economy Trade and Industry Tadahiro Matsushita on Monday met with Mayor Yuko Endo of Kawauchi Village, one of the municipalities, and said the advisory would be lifted by around Friday.

The municipalities are located in a ring between 20 and 30 kilometers from the Fukushima Daiichi

plant. Residents of the areas have been advised to evacuate or remain indoors in the event of an emergency. About 29,000, or half of them, have evacuated.

The advisory covers the entire town of Hirono and parts of Naraha, the village of Kawauchi and the cities of Tamura and Minamisoma.

Mayor Endo said government support is essential to realizing the village's plan to allow all evacuees to return by March.

Matsushita assured Endo that he will take steps to lift the evacuation advisory.

The 5 municipalities had earlier submitted to the government plans to decontaminate the areas and restore lifelines to meet conditions for lifting the advisory.

Anti-nuclear experts join energy panel

Japan's industry ministry has decided to add experts who favor reducing the nation's reliance on nuclear power to a panel tasked with crafting a new energy policy.

Industry minister Yukio Edano revealed the decision on Tuesday.

The new panel is to hold its first meeting on October 3rd. It will review Japan's mid- to long-term energy policy, which had been focused on increasing nuclear power until the March 11th disaster.

Compared to previous panels, the new panel includes more experts who have been critical of the government's energy policies, such as NPO leaders Tetsunari Iida and Hideyuki Ban.

There will be no representatives from the energy industry, such as power companies.

The panel is to meet once or twice a month and detail a new energy program by around next summer.

Industry minister Edano said that the panel members were chosen so that a balanced debate could be held. He added the meetings will be posted on the Internet and he hopes they will be as open as possible.

Tuesday, September 27, 2011 13:37 +0900 (JST)

Anti-nuclear researcher to sit on gov't panel on energy policies

Tetsunari Iida (Mainichi)

A researcher who is calling for a decrease in Japan's reliance on nuclear power will be appointed to a government panel to review the country's energy policies, officials said.

The Economy, Trade and Industry Ministry will name Tetsunari Iida, head of the Institute for Sustainable Energy Policies, as a member of a subcommittee on basic energy policy set up under the Advisory Committee on Energy and Natural Resources. However, the ministry did not appoint anybody representing energy industries, including the electric power industry, to the subcommittee.

Also among its 25 members are Ritsumeikan University professor Kenichi Oshima and others critical of Japan's nuclear power policy as well as Osaka University visiting professor Tatsuo Hatta, who has called for a split of power suppliers into power generating and power transmitting firms. The panel will be headed by Akio Mimura, chairman of Nippon Steel Corp.

Economy, Trade and Industry Minister Yukio Edano said he selected the panel members to enable well-balanced discussions on overall energy policies.

The panel will also hold meetings to listen to opinions from those representing energy industries.

At its first meeting on Oct. 3, the subcommittee will begin to review the current basic energy plan, which calls for installations of new nuclear power stations, and work out a new plan in summer next year.

On behalf of the ministry, the panel will report its opinion based on the new plan to the government's Energy and Environment Council, which will reflect it in comprehensive energy policies it will compile by summer 2012.

Deliberations on the issue will be broadcast live on the Internet.

(Mainichi Japan) September 27, 2011

Fukushima N-response center lost functions

The Yomiuri Shimbun

A power loss shut down an off-site emergency response center near the Fukushima No. 1 nuclear power plant for half a day after the Great East Japan Earthquake on March 11, delaying the initial response to the nuclear disaster at the power plant, according to sources.

According to the Nuclear and Industrial Safety Agency, **the center lost its external power supply immediately after the earthquake, and an emergency diesel generator stopped operating soon after. Due to the power loss, agency officials stationed at the center were unable to use important equipment such as monitors that show conditions inside the plant.**

The agency, which believes the earthquake caused the generator to break down, had not taken any anti-seismic reinforcement measures to protect the generator, the agency said.

The government panel tasked with investigating the nuclear crisis has begun studying the case, according to the sources.

The off-site center is located in Okumamachi, Fukushima Prefecture, about five kilometers from the nuclear power plant.

Based on the Law on Special Measures Concerning Nuclear Emergency Preparedness, **22 off-site emergency response centers have been set up near nuclear power plants around the nation**, including the one in Okumamachi.

In the event of nuclear accidents, the government is to establish local emergency headquarters at the centers, where officials of the central and local governments and power plant operators are to share information about accidents and related information such as the evacuation of residents, and discuss countermeasures.

According to the Nuclear and Industrial Safety Agency and the Fukushima prefectural government, the emergency generator went on when the external power supply was lost immediately after the earthquake occurred at 2:46 p.m.

However, the generator stopped working within about one hour after the earthquake, and the center lost all its functions. The generator was on the first floor of the center.

Agency officials moved to the Fukushima prefectural government's Environmental Radioactivity Monitoring Center next to the off-site center building. The government's local emergency headquarters for the nuclear crisis was established at the response center at about 7 p.m., but the agency officials had to continue working in one of the rooms of the radioactivity monitoring center.

The radioactivity monitoring center became so crowded with people that the activities of the agency officials and Fukushima prefectural government officials were delayed. "We weren't able to perform some of the work that should have been done soon after the earthquake, such as preparing to measure radiation doses," a Fukushima prefectural government official said.

Due to the power loss, officials were unable to use a videoconference system at the center, which connects the center to the central and local governments, and a TV monitor displaying communications between the Fukushima No. 1 nuclear power plant and Tokyo Electric Power Co.'s head office in Tokyo.

At that time, the Nuclear and Industrial Safety Agency in Kasumigaseki, Tokyo, did not have a TV monitor displaying communications between the Fukushima No. 1 plant and TEPCO.

The power was out when Motohisa Ikeda, then senior vice minister of the Economy, Trade and Industry Ministry, arrived at the response center at midnight with senior officials of the Nuclear and Industrial Safety Agency to serve as the chief of the local emergency headquarters.

Sometime after Ikeda's arrival, an electrician determined that a pump sending diesel oil to the generator from a tank placed in the basement was not working due to a **faulty switch on the pump's control panel**. The electrician fixed the fault, and the center's functions were restored at about 3 a.m. the next day.

According to the agency, the emergency generator has the capacity to provide electricity to the off-site center for two days. The agency did not find any defects in the generator during a periodic inspection in February.

The agency said it had not taken any antiquake measures for the emergency generator as operational regulations of the Law on Special Measures Concerning Nuclear Emergency Preparedness do not require any. The agency believes the shock of the earthquake caused the generator to break down. The temblor registered in the upper 6 level on the Japanese seismic intensity scale of 7 in areas around the off-center site.

On March 15, the agency ordered officials to evacuate from the center after radiation levels went up due to the repeated hydrogen explosions at the power plant's nuclear reactors and the shortage of water and food. The local emergency headquarters was moved to Fukushima city, about 60 kilometers from the nuclear power plant.

Several other failures of the center to prepare for major earthquakes became evident after the March 11 disaster, such as failing to cover the building with materials to block radiation.

A spokesman of the Nuclear and Industrial Safety Agency said: "**Off-site center buildings meet the quake-proofing standards of the Building Standards Law, but we apparently did not pay attention to the earthquake resistance of generators.** We deeply regret the inconvenience caused to local residents [near the power plant].

"The Nuclear Safety Commission is now discussing matters related to off-site centers, such as the suitability of their locations. We'll take necessary measures on off-site centers after the commission announces its conclusion."

(Sep. 27, 2011)

Govt resumes review of Japan's nuclear policy

Japan's Atomic Energy Commission has resumed discussions on revising the country's nuclear policy.

Work to revise the policy started last December, but was suspended after the accident at the Fukushima Daiichi nuclear plant in March.

Following the disaster, the commission added members who are experts on safety and take a tough stance on nuclear power.

On Tuesday, commission head Shunsuke Kondo apologized for the accident. He said it left him unsure what the panel should do, but that he decided the panel must resume work to fulfill its duty.

Some commission members called for shutting down all of Japan's nuclear plants and promoting alternate energy sources. Others said it's too early to determine long-term nuclear policy, as the Fukushima Daiichi plant remains out of control.

Members advocating nuclear power noted that resource-poor Japan must aim for a realistic energy policy.

The policy on nuclear power use, research and development was drawn up in 1956 and has been revised about every 5 years. It was last revised 6 years ago. The policy calls for promotion of nuclear power despite accidents at nuclear facilities and scandals such as cover-ups of trouble, and for at least 30 percent reliance on nuclear power after 2030.

The commission is to draw up a new policy outline over the next year.

Tuesday, September 27, 2011

Panel: TEPCO unprepared for Fukushima accident

A government panel says Tokyo Electric Power Company was unprepared for the accident at the Fukushima Daiichi nuclear plant and failed to take steps to minimize the damage.

The panel investigating the accident held its third meeting on Tuesday. It met behind closed doors, saying that allowing media access would negatively affect its interviews with the plant's staff.

Panel leader Yotaro Hatamura told reporters after the meeting that they are looking into whether Tokyo Electric was ready to protect the plant from tsunami and other severe accidents.

Hatamura said the company could have taken more effective steps after the March 11th tsunami if it had come up with ways to minimize the damage.

He added that the panel will further investigate why the utility was unable to contain the damage from the accident.

The panel is scheduled to release an interim report on its probe at the end of the year.

Wednesday, September 28, 2011 00:56 +0900 (JST)

Alcoholic products to be tested for radiation

Japan's tax officials have decided to check alcoholic beverages produced near the Fukushima Daiichi nuclear plant for radiation to ensure their safety.

The National Tax Agency says testing will be conducted starting next month on all kinds of alcoholic drinks, **including sake, wine, and beer, produced at breweries and factories located within 150 kilometers of the plant.**

Brewing facilities outside the radius will also be randomly tested.

Taxation bureaus in 6 major cities including Tokyo and the National Research Institute of Brewing will check water samples used for alcoholic products.

If they find radioactive cesium or iodine above the government-set safety limit in any of the samples they will ask local authorities to issue a shipment ban or take other measures, as necessary.

The National Tax Agency says it will post the test results on its website.

Rice and barley, the main ingredients for alcoholic beverages, have already been tested for radiation.

The agency hopes the additional testing will put consumers at ease.

Tuesday, September 27, 2011

Fukushima City to decontaminate all houses

Fukushima City, about 60 kilometers from the crippled Dai-ichi nuclear power plant, plans to remove radioactive materials from all private houses in the city.

The plan was decided after high levels of radiation were detected in some areas of the city. The amounts were close to a level that would prompt authorities to recommend evacuation of nearby residents.

Some people concerned about possible health risks to their children have already moved out of the city.

The plan aimed at substantially lowering radiation levels in the air for the next 2 years includes decontamination of all 110,000 households in the city.

Of those, highly contaminated houses where children of high school age or younger live will be given extra thorough cleaning.

Under the plan, professional cleaners commissioned by the city will scrub radioactive substances from roofs and ditches of the houses, and remove concrete, which radioactive material tends to adhere to. They will also decontaminate roofs and ditches of other nearby houses, but residents will be required to remove surface soil and weed gardens by themselves.

The city says it will recruit volunteers from around the nation, if necessary, and send them to households that need manpower. The city also plans to decontaminate parks and community halls.

But it has yet to be determined how the contaminated soil and other materials will be disposed of.
[what about all that water used for cleaning ?]

<http://fukushima.over-blog.fr/article-presence-d-hydrogene-inquietante-a-la-centrale-de-fukushima-daichi-85254542.html>

Risque d'une nouvelle explosion d'hydrogène au réacteur 1 de Fukushima

Le Monde | 24.09.11 | 13h42 • Mis à jour le 25.09.11 | 18h51

Une concentration anormalement élevée d'hydrogène a été détectée, jeudi 22 septembre, dans une conduite reliée à l'enceinte de confinement du réacteur 1 de la centrale nucléaire de Fukushima. De 1 %, elle reste inférieure au 4 % considérés comme pouvant provoquer une explosion, au cas où cet hydrogène entrerait en contact avec une concentration d'oxygène supérieure à 5 %.

La découverte de la concentration d'hydrogène à un niveau *"supérieur aux attentes"*, selon l'opérateur du site, la Compagnie d'électricité de Tokyo (Tepco), a été faite par des techniciens qui travaillaient sur l'installation d'un nouveau système de ventilation lié à l'enceinte de confinement. Ils ont découvert dans le tuyau et en deux endroits une forte concentration de plusieurs gaz inflammables, dont de l'hydrogène.

Lors d'une conférence de presse samedi, Junichi Matsumoto, porte-parole de Tepco, a déclaré qu'*"en l'absence d'un facteur détonnant, on ne peut pas dire qu'il existe, dans l'immédiat, un risque élevé d'explosion"*. L'entreprise souhaite effectuer des mesures complémentaires pour évaluer avec précision la quantité d'hydrogène présente.

Cette découverte soulève des inquiétudes car ce sont des explosions d'hydrogène, consécutives à la surchauffe des réacteurs après l'arrêt des systèmes de refroidissement, qui ont provoqué des dommages, entre le 12 et le 15 mars, aux enceintes de confinement des réacteurs 1, 2 et 3 de la centrale. Des explosions qui ont provoqué la diffusion de panaches radioactifs fortement radioactifs : le dégagement de césium 137 aurait été 168,5 fois plus élevé que lors de l'explosion de la bombe atomique larguée sur Hiroshima, en 1945.

Au mois d'avril, Tepco, qui cherche à reprendre le contrôle des installations fortement endommagées, a mis en place des circuits d'injection d'azote dans les réacteurs pour empêcher de nouvelles explosions. Ces injections permettent de réduire la quantité d'oxygène, et donc de limiter ce risque. Mais la situation reste fragile.

Le refroidissement des réacteurs en circuit fermé est en cours depuis le mois de juillet et la température des réacteurs 1 et 3 a pu être abaissée sous les 100 °C, début septembre. Cela signifie que les techniciens sont sur le point de réussir l'arrêt à froid de ces réacteurs, ce qui est l'un des principaux objectifs de l'opérateur.

Mais les installations mises en place à cet effet restent à la merci du moindre problème. Le typhon qui a frappé le Japon du 20 au 22 septembre et qui est passé à la verticale de la centrale a obligé les techniciens à suspendre plusieurs opérations. Il a même provoqué une élévation importante des niveaux de radiations : 1,38 microsievert par heure a été observé à Tokyo. Et l'ensemble du site reste à la merci d'un puissant séisme et d'un tsunami.

Industry ministry underreported opponents to reactivation of nuclear plant in Kyushu

The Ministry of Economy, Trade and Industry (METI) is suspected of underreporting the number of people who were opposed to the reactivation of the Genkai Nuclear Power Plant in Saga Prefecture, sources close to the case said on Sept. 28.

If about 100 respondents to an Internet broadcast survey who were excluded from counting because their responses were sent after the deadline were included, the total number against would far outnumbered those who were in favor of reactivating the plant.

Moreover, one of the online responses pointed to the possibility that Kyushu Electric Power Co., the operator of the plant, instructed employees as well as subsidiaries to send opinions to the program to express support for reactivation in an apparent attempt to manipulate public opinion, but the ministry failed to act on the claims.

METI's Agency for Natural Resources and Energy denied that it attempted to decrease the ratio of those against reactivation.

"We stopped accepting opinions during the broadcast, calculated them and released the results during the program. We never tried to make it look as though those who were opposed to the resumption of operations at the plant outnumbered those who were in favor by a smaller margin," said an official with the agency's public relations division.

METI had announced that 589 messages were sent from viewers to the program broadcast online on June 26 -- 286 expressing support for the resumption of operations at the plant and 163 against reactivation.

Of the messages in support of the resumption, 141 messages subsequently turned out to have been sent by Kyushu Electric insiders. After these messages are excluded, messages against reactivation slightly outnumbered those in favor.

If about 100 messages sent to the broadcaster after the deadline were included, the ratio of those opposed to reactivation becomes larger, according to the sources.

Gov't to decontaminate areas with radiation exposure of 5 millisieverts or more per year

An experiment to decontaminate soil is conducted in Kawamata, Fukushima Prefecture, on Aug. 11. (Mainichi)

The Environment Ministry has decided to decontaminate areas where people could be exposed to radiation of 5 millisieverts or more per year by removing up to 28.78 million cubic meters of radioactively contaminated soil in Fukushima and four other adjacent prefectures affected by the ongoing crisis at the Fukushima No. 1 Nuclear Power Plant.

The areas subject to the decontamination project are in Fukushima, Miyagi, Yamagata, Ibaraki and Tochigi prefectures. A huge temporary storage facility for contaminated materials needs to be built, and therefore the government is likely to have tough talks with local municipalities on selecting a space for such a facility.

Under the special measures bill passed into law in August to deal with radiation contamination and debris, the environment minister designates highly contaminated areas as "special decontamination areas" and the central government becomes directly in charge of decontaminating such areas. The central government also designates other areas with certain levels of contamination as "priority inspection areas for contamination" and local governments are to check the levels of contamination in those areas to determine locations to be decontaminated and actually decontaminate them.

In mapping out the decontamination program for those areas, the Environment Ministry decided that areas where people could be exposed to radiation of 5 millisieverts or more per year should be decontaminated. On the reason to set the levels of radiation at 5 millisieverts or more per year, the Environment Ministry said, "If the dose of radiation exposure is less than 5 millisieverts, the dose of additional radiation exposure will fall below the official dose limit of 1 millisievert as it decreases with the passage of time and is spread by rain and wind."

The amounts of soil to be removed are calculated on these assumptions, with 5 centimeters of topsoil being removed from contaminated areas. For calculating the amounts of soil to be decontaminated in forests, the areas are divided into three sections of 10 percent of the whole areas, 50 percent and 100 percent.

Workers measure the ground near a rain water outlet in Minamisoma, Fukushima Prefecture, on June 12. (Mainichi)

As a result, if 100 percent of the designated areas were to be decontaminated, the amounts of radioactive soil and other materials to be removed would reach 28.785 million cubic meters, which

would fill the Tokyo Dome stadium 23 times. Of the estimated total amounts of soil and other materials to be removed, 1.02 million cubic meters comes from residential and urban areas, 17.42 million cubic meters from farmland, and 8.75 million cubic meters from forests. The total area is 2,419 square kilometers, which is equal to about 17 percent of Fukushima Prefecture.

The Environment Ministry said it would try to work out specific decontamination plans by the end of this year.

(Mainichi Japan) September 28, 2011

3 Fukushima reactors cooled below 100 degrees

The temperature of another troubled reactor at the Fukushima Daiichi nuclear power plant has fallen below 100 degrees Celsius for the first time since the nuclear disaster in March.

Tokyo Electric Power Company or TEPCO says the temperature in the lower area of the Number 2 reactor stood at 99.4 degrees at 5 PM on Wednesday.

Temperatures at the Number 1 and 3 reactors have been maintained below 100 degrees Celsius since August.

The utility says its cooling efforts have achieved results although it is too early to say that it has attained a state of cold shutdown for all 3 troubled reactors.

Cold shutdown is a state where temperatures below 100 Celsius are sustained and the situation remains stable.

The utility now says it is important to ensure a reliable cooling system to achieve cold shutdown.

OCTOBRE 2011

October 01, 2011

Ministry maps strontium, plutonium fallout

<http://ajw.asahi.com/article/0311disaster/AJ2011100112896>

Levels of strontium in soil near the Fukushima No. 1 nuclear power plant are up to six times the highest concentrations deposited in Japan by pre-1980 atmospheric nuclear tests, according to the science ministry.

Official maps of soil contamination by strontium and plutonium were published for the first time on Sept. 30 and reveal that, while concentrations are dwarfed by the radioactive cesium leaked from the stricken plant since March 11, significant quantities are present in some locations.

The survey team collected soil samples within a 100-km radius of the nuclear plant between June 6 and July 8.

The concentrations of different nuclides of strontium and plutonium per square meter were analyzed at 100 locations, including each of the 59 municipalities within an 80-km radius of the plant. Forty-one additional locations within the 20-km no-entry zone were studied.

Strontium-90, which has a half-life of about 30 years, was most concentrated at a location in Futaba town within the zone. The 5,700 becquerels per square meter detected there was six times the maximum of 950 becquerels per square meter found during fiscal 1999-2008 nationwide surveys by the science ministry and attributed to nuclear tests.

Strontium-90 concentrations exceeding 950 becquerels per square meter were detected at eight locations. Seven of them were either within 20 km of the plant or beyond that radius to the northwest.

The maximum concentration of plutonium-238 was 4 becquerels per square meter, while the maximum combined concentration of plutonium-239 and plutonium-240 was 15 becquerels per square meter. At all locations, the plutonium concentrations were below the maximum levels detected before the accident.

At six locations lying either within a 30-km radius of the nuclear plant or beyond that radius to the northwest, however, the proportion of total plutonium consisting of plutonium-238 was much higher than in residual levels left by the nuclear tests, clearly indicating that the contamination was caused by the Fukushima disaster, the ministry said. Plutonium from the latest accident had previously only been detected on the grounds of the Fukushima No. 1 nuclear plant.

On average, the strontium concentrations were less than 1 percent of the concentrations of radioactive cesium.

"Both the plutonium and strontium concentrations are very small compared to those of cesium. Future assessment of the impact of radiation exposure and the design of decontamination measures should be focused on cesium," a ministry official said.

The current, temporary safety standard for cesium in food includes a 10-percent increment that accounts for strontium.

"The ratio (of less than 1 percent) given by the latest study is low. You will probably not have to worry about strontium as long as cesium remains below the threshold level," said Shigeo Uchida, director of the Research, Development and Support Center at the National Institute of Radiological Sciences.

Wherever there is radioactive cesium, strontium is believed to exist in a low but fixed ratio to the amount of cesium. Strontium is easily soluble in water and resembles calcium in its chemical properties. It can accumulate in human bones.

Plutonium-239, which is used in the manufacturing of atomic bombs and nuclear fuel rods, has a half-life of about 24,000 years. It is not thought to be easily absorbed by digestive organs and tends to be excreted when taken into the body with food.

from Yomiuri : Tests show all 143 reactors in EU safe

Takehito Kudo / Yomiuri Shimbun Correspondent

Number of nuclear reactors subject to stress tests in EU

France	58
Britain	19
Germany	17
Sweden	10
Spain	8
Belgium	7
Czech Republic	6
Finland	4
Hungary	4
Slovakia	4
Romania	2
Bulgaria	2
Slovenia	1
Netherlands	1

BRUSSELS--All 143 nuclear reactors in 14 European Union countries that were subjected to "stress tests" are considered free from grave safety risks, according to interim reports disclosed by Friday.

A stress test is a new, more stringent type of reactor resilience inspection to determine safety risks.

The nuclear power plant operators of the 14 nations have submitted the interim reports to the European Commission, the EU's executive arm, via the respective countries' nuclear regulatory organizations.

If no major changes to the interim reports are made in the final reports scheduled to be worked out in June, no reactor is likely to be shut down and decommissioned, according to experts.

Some civic bodies, however, are skeptical, saying the tests are woefully inadequate in making nuclear safety assessments.

The EU countries embarked on the stress tests in June in the wake of the crisis at Tokyo Electric Power Co.'s Fukushima No. 1 nuclear power plant.

The tests are designed to gauge whether the reactors are capable of withstanding natural disasters or other threats, including terrorist attacks. The tests exceed the standards set by individual governments.

The French Nuclear Safety Authority (ASN), the nuclear safety watchdog of France, which has 58 reactors, the largest number among EU nations, said it had reached the conclusion that none of the country's 150 nuclear facilities, including nuclear power plants under construction and nuclear research laboratories, need to undergo emergency safety measures.

British regulators believe that additional safety arrangements are needed for some of its nuclear power plants, such as enhancing measures against flooding and strengthening cooling systems. They said, however, that no reactor appeared to be immediately vulnerable to safety problems.

In the Czech Republic, where old-fashioned reactors designed during the days of the former Soviet Union are still in operation, regulators said none of its reactors required any urgent safety measures.

The interim reports presented by other countries also said their reactors had sufficient resilience to withstand flooding and other natural disasters.

Dutch nuclear regulators, however, described the interim report by the country's nuclear facility operator inadequate, and are reportedly planning to call for new stress tests.

The European Commission is scheduled to explain the interim reports at a summit meeting in December of EU member nations.

Mutual verification procedures will then be carried out among EU nations, with the participation of officials from the commission and third-party experts, before submission of the final reports, commission officials said.

Radioactive waste piles up at Fukushima nuclear plant as disposal method remains in limbo

Workers at the Fukushima No. 1 Nuclear Power Plant stand around the radioactive water decontamination system "Sally" in this photo provided by TEPCO.

Three months after the start of full-scale water circulation system operations at the crippled Fukushima No. 1 Nuclear Power Plant, high-level radioactive waste has kept piling up amid no clear indications of its final disposal destination.

As of Sept. 27, plant operator Tokyo Electric Power Co. (TEPCO) had accumulated about 4,700 drums of radioactive waste after three months of cesium decontamination operations initially using U.S. and French equipment which was later joined by Toshiba Corp.'s "Sally" system in August.

Since the start of October, TEPCO has conducted the plant's water circulation operations using the Sally system alone while relegating its U.S. and French counterparts built by Kurion Inc. and Areva SA, respectively, to backups.

The Kurion and Sally systems are designed to purify decontaminated water through an absorption unit called a "vessel" that contains zeolites. The vessel is changed every few days and the used vessels become radioactive waste.

Areva's water treatment system filters contaminated water by having sand absorb radioactive materials and precipitate with the help of chemicals. But the treatment produces highly polluted sludge.

According to TEPCO, radioactive waste as of Sept. 27 included 210 Kurion-made vessels (a total of about 307 cubic meters) with each vessel measuring 0.9 meters in diameter and 2.3 meters in height and 581 cubic meters of sludge via the Areva unit.

The radioactive waste has been kept at a temporary storage site on the premises of the Fukushima plant, which was heavily damaged by the March 11 earthquake and tsunami, and subsequent hydrogen explosions and meltdowns. But TEPCO has been unable to fully grasp the details such as the types and the concentration of nuclear materials.

Professor Akio Koyama at Kyoto University Research Reactor Institute says, "The density of high-level decontaminated water is believed to be a maximum 10 billion becquerels per liter, but if it is condensed to polluted sludge and zeolites, its density sometimes increases by 10,000 times. The density cannot be dealt with through conventional systems."

Thyroid gland irregularities found in young evacuees from Fukushima

NAGANO (Kyodo) -- Hormonal and other irregularities were detected in the thyroid glands of 10 out of 130 children evacuated from Fukushima Prefecture, a Nagano Prefecture-based charity dedicated to aid for the victims of the 1986 Chernobyl nuclear accident said Tuesday.

The Japan Chernobyl Foundation and Shinshu University Hospital did blood and urine tests on youngsters aged up to 16 including babies under the age of one for about a month through the end of August in Chino, Nagano, when the children stayed there temporarily after evacuating from Fukushima.

As a result, one child was found to have a lower-than-normal thyroid hormone level and seven had thyroid stimulation hormone levels higher than the norm. The remaining two were diagnosed with slightly high blood concentrations of a protein called thyroglobulin, possibly caused by damage to their thyroid glands.

Three of the 10 children used to live within the 20-km no-go zone around the nuclear plant and one was from the so-called evacuation-prepared area in case of emergency in areas between 20 and 30 kilometers from the plant, while six others were from towns outside such zones.

"At present, we cannot say the children are ill but they require long-term observation," said Minoru Kamata, chief of the foundation. No clear link has been established between the children's condition and the radiation from the crippled Fukushima Daiichi nuclear power plant, according to the nonprofit organization.

Radioactive iodine tends to get lodged in children's thyroid glands more than those of adults, placing youngsters at greater risk of developing disorders and diseases including cancer.

High dosage of cesium found in soil outside Fukushima no-go zone

TOKYO (Kyodo) -- High levels of radioactive cesium were found in an independent study in a Fukushima city district, prompting a citizens group and others involved to urge the government on Wednesday to promptly designate the area as one of the contamination hot spots for possible evacuation and ensure proper decontamination.

Up to 307,000 becquerels of cesium per kilogram of soil was detected in the Sept. 14 survey, triple that of the benchmark above which the government requires tainted mud to be sealed by concrete. The

contamination is believed to have been caused by radiation leaked by the Fukushima Daiichi nuclear plant crippled in the March 11 earthquake and tsunami disaster.

The readings are comparable to the high levels in special regulated zones where evacuation was required after the 1986 Chernobyl accident, said the citizens group, Citizens Against Fukushima Aging Nuclear Power Plants.

It urged the government to designate the area as one of the hot spots, where residents are urged to evacuate, albeit not mandatory, due to accumulation of radiation in certain districts and would be eligible for state assistance if they decide to do so.

A government map displaying radiation levels in the area around the Fukushima No. 1 Nuclear Power Plant.

Kobe University professor Tomoya Yamauchi, who was in charge of the study that tested soil samples from five locations in and around the district, noted that decontamination conducted in some of the areas tested has not yet succeeded in reducing radiation back to the same levels prior to the March accident.

The Japanese government currently has designated two categories of evacuation zones -- the 20-kilometer no-go zone around the Fukushima Daiichi plant, and hot spots outside the zone where radiation level is expected to top 20 millisieverts a year.

The city of Fukushima is about 60 km from the crippled plant.

Progress on nuclear plant seawalls

In response to the accident at the Fukushima nuclear power plant, the government instructed the nation's power companies on March 30 to take urgent safety measures to prevent damage from tsunami.

The utilities are preparing their anti-tsunami measures, including the construction of seawalls.

45 of the 54 reactors around the country are planning to build seawalls.

Construction is expected to be completed as early as spring 2012, or in the next 3 years at the latest.

Wednesday, October 05, 2011 18:54 +0900 (JST)

Construction of seawall begins at nuclear plant

A Japanese electric power company has begun building an anti-tsunami embankment at a nuclear power plant on the Sea of Japan coast.

Hokuriku Electric Power Company on Wednesday started construction of a reinforced concrete seawall at the plant in Shika Town, Ishikawa Prefecture. The wall is 4 meters high, 700 meters long, and sits 11 meters above the sea level.

A 15-meter-high tsunami caused flood damage at the Fukushima Daiichi nuclear power plant following the March 11th earthquake. After the disaster, the government instructed utilities to take anti-tsunami measures.

Hokuriku Electric plans to install a new drainage gate to minimize damage to plant facilities in case seawater manages to climb over the wall and flood the plant.

Other emergency safety measures to be taken by the utility include installing an extra pump to cool reactors with seawater and a power source to operate a valve for venting steam out of reactors.

The company intends to complete construction by the end of March 2013.

Wednesday, October 05, 2011 18:15 +0900 (JST)

Noda dismisses speculation of turning back in favor of nuclear power

Following criticism from opposition parties, Prime Minister Yoshihiko Noda is striving to sweep away speculation that he has turned back in favor of nuclear power.

In an Oct. 5 meeting of the House of Representatives special committee on recovery from the quake and tsunami, Noda rejected the suggestion that he was aspiring to export nuclear power overseas, stating, "We're not going to rush forward and form new agreements (with other countries) or engage in marketing efforts."

His comments came after he indicated in a United Nations high-level meeting on nuclear safety and security in New York on Sept. 22 that Japan would continue to sell nuclear power plants to other countries. In the U.N. meeting he stated "Japan is determined to raise the safety of nuclear power generation to the highest level in the world," and "Japan stands ready to respond to the interest of countries seeking to use nuclear power generation."

Opposition parties responded by saying that his stance on eliminating reliance on nuclear power had wavered.

Replying to the criticism, Noda told a news conference on Sept. 30, "What I said (at the U.N. meeting) has been taken as if I were giving exports the green light, but I've said nothing of the sort."

In a related development, Minister of Economy, Trade and Industry Yukio Edano told the lower house special committee on quake and tsunami recovery on Oct. 5, "Deals in which negotiations are already underway involve issues of trust, so we will go ahead with them." He indicated that the government had not departed from its statement approved by the Cabinet in August that the nation would proceed with nuclear power deals that were already underway.

(Mainichi Japan) October 6, 2011

Your Party chief Watanabe urges end to nuclear power

Yoshimi Watanabe, leader of the reform-minded Your Party, said Oct. 6 that Japan should end its dependence on nuclear energy and liberalize its electricity industry in the aftermath of the crisis at the Fukushima No. 1 Nuclear Power Plant.

"We want to extricate Japan from its dependence on nuclear energy," Watanabe said at a meeting at the Foreign Correspondents' Club of Japan. He proposed introducing a system to hold national and local referendums to help deregulate the nation's electricity industry.

Through such referendums, he said, Japanese consumers would be able to freely choose electric power companies and their sources of electric power. He also called for creating an independent regulatory agency to oversee the industry.

Your Party's calls for an end to over-reliance on bureaucrats, and further decentralization, along with its nuclear-free policy and strong opposition to tax increases, are catching the fancy of growing numbers of Japanese people who have been disillusioned with both the ruling Democratic Party of Japan (DPJ) and the largest opposition Liberal Democratic Party (LDP).

The two-year-old party's vocal opposition to tax increases, excessive bureaucratic control in the government and nuclear power means that "we are of course exposing ourselves to tremendous friction and tremendous pressure to change," a defiant Watanabe said.

According to a recent poll by the Mainichi Shimbun, Your Party was the third most popular political party in Japan with 7 percent of respondents in favor of it, after the LDP at 18 percent and the DPJ at 16 percent. The figure surpasses the New Komeito party's 5 percent support rating.

Watanabe, 59, said Your Party will field more than 100 candidates in the next House of Representatives election due to take place in two years. The party currently has five members in the lower house and 11 in the House of Councillors. He added that his party's objective over the next two years is to replace New Komeito as the nation's third largest political party, earning a casting vote. (By Shiro Yoneyama, Staff Writer)

(Mainichi Japan) October 6, 2011

Gov't panel eyes higher interim radiation exposure limit

TOKYO (Kyodo) -- A government panel on reviewing radiation dose standards plans to propose that the government adopt an interim annual radiation exposure limit between 1 to 20 millisieverts for ordinary people instead of the current 1 millisievert limit, panel sources said Wednesday.

The recommendation by a group under the panel, headed by Otsura Niwa, a professor emeritus at Kyoto University, would be employed when the government reviews provisional radiation limits for food products and soil, many of which were hurriedly set after the start of the nuclear crisis at the Fukushima Daiichi power plant.

However, the plan to raise the annual radiation exposure limit for ordinary people could be criticized for endangering health, potentially affecting the subsequent review process, observers said.

The group has apparently determined it is difficult at present to maintain the 1 millisievert limit.

The group envisions setting an achievable interim limit without specifying a numerical target, while looking at the 1 millisievert limit as a long-term goal, according to the sources.

Prior to the disaster at the Fukushima complex, Japan had few standards for radiation exposure or radioactive materials in the event of emergencies.

After the start of the nuclear crisis triggered by the March 11 earthquake and tsunami, government ministries and agencies rushed to set provisional limits for radiation exposure and radioactive materials as problems arose.

(Mainichi Japan) October 6, 2011

Gov't panel mulls interim goals on radiation dose

A government panel is calling for Japan's one-millisievert annual radiation limit to be eased for the interim, saying it will be difficult to restrict exposure in some areas near the troubled Fukushima nuclear plant.

The environment is contaminated by radioactive substances in areas hit by fallout from the Fukushima Daiichi nuclear power plant, causing concern that residents may be exposed to radiation for long periods.

The panel on radiation believes it will be difficult to keep their dose below the one-millisievert limit set by the government for normal times and proposed on Thursday to set an interim exposure target.

It says the target should be set between one and 20 millisieverts in line with recommendations by the International Commission for Radiological Protection.

The panel says the target should be lowered in steps as decontamination progresses.

It adds that targets could differ by region and that residents should have a voice in setting the targets.

The panel will wrap up its proposal at its next meeting, but its plan to ease the radiation exposure limit is expected to arouse controversy.

Thursday, October 06, 2011 15:39 +0900 (JST)

True radiation decontamination still a long way away

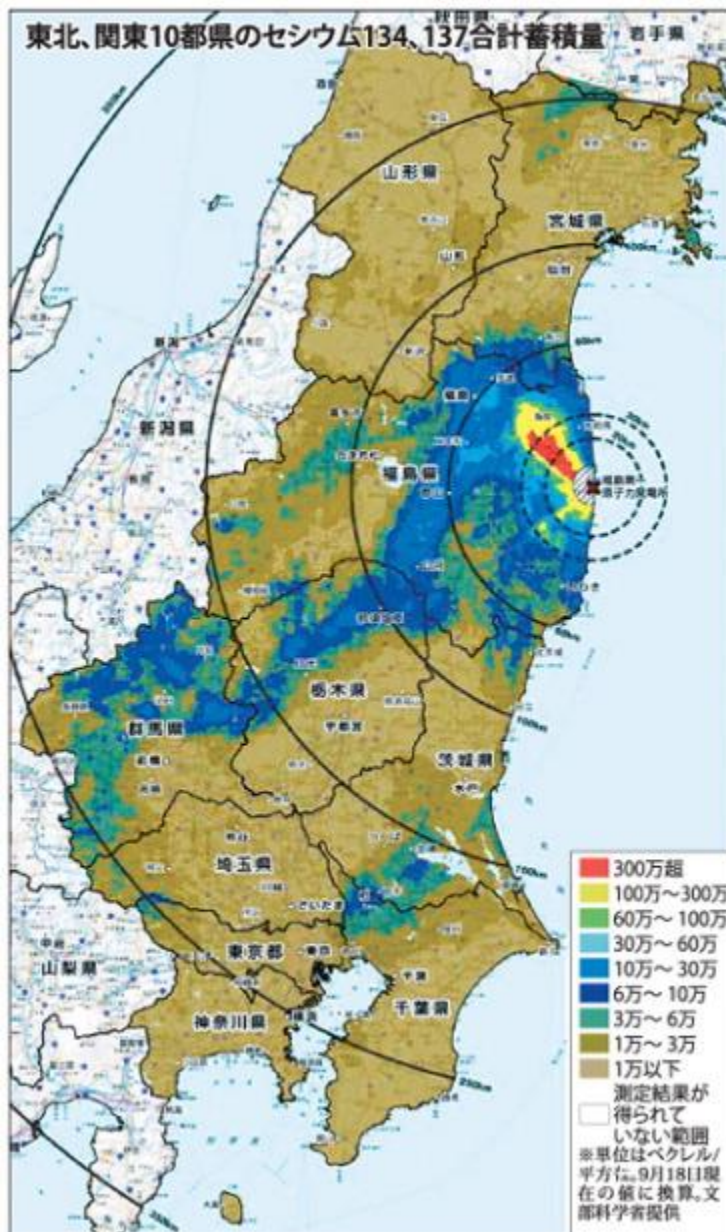

Though the government last month lifted the "emergency evacuation preparation zone" designation of some areas greatly affected by the ongoing crisis at the Fukushima No. 1 Nuclear Power Plant, radiation decontamination efforts are still taking place in areas with high levels of radiation.

The three main decontamination methods that have been highly publicized through media reports are: the stripping away of surface soil from school playgrounds and athletic fields, the removal of mud accumulated in gutters, and the washing of roofs using high-pressure water cleaners. While the first method is considered effective, the remaining two have been found to be effective only to a certain point, and some especially warn against overestimating the effects of high-pressure water cleaners.

"It might make you feel like you're decontaminating, but there's a limit to the amount of radioactive cesium that's caked onto roofs that can be eliminated with high-pressure water cleaners," says Kunihiro Yamada, a professor of environmental science at Kyoto Seika University. "The water cleaners wash surface dirt off, but then that tainted water goes into sewers and can contaminate rivers, thereby affecting farm goods and seafood. If people in highly populated areas were to begin using water cleaners, we may end up finding people forcing tainted water onto each other."

Since his launch of the "Radiation Contamination and Recovery Project" with colleagues from Fukushima University and Osaka University in May, Yamada has been running trials in the city of Fukushima on methods of decontamination that residents can undertake themselves. He has compiled a

manual, which is available on the website of the Society for Studies on Entropy, an organization of which he is a representative.

A government map displaying radiation levels in 10 prefectures relatively close to the Fukushima No. 1 Nuclear Power Plant. Areas in red show over 3 million becquerels of cesium per square meter, whereas those in light brown show less than 10,000. (Data as of Sept. 18. Image courtesy of the Ministry of Education, Culture, Sports, Science and Technology)

What exactly is meant by the "limitations" of high-pressure water cleaning, a method that is featured in manuals available from both the central government and the Fukushima Prefectural Government?

According to Yamada, radioactive cesium is believed to exist in three states: dissolved in water, loosely bonded to organic materials such as moss and leaves, or tightly bonded to rock such as silicate salt. In other words, if soil is removed and washed away with high-pressure water cleaners, radioactive cesium found in surface soil and gutters can be eliminated. The cesium that has become affixed to roofs remains, however.

At the request of Fukushima residents and civic groups, on Sept. 14, Kobe University Professor Tomoya Yamauchi, a radiation metrology specialist, measured radiation levels in Watari, which was believed to have some of the highest radiation levels in the city of Fukushima. At a building used for afterschool activities for elementary school children, Yamauchi found 0.33 microsieverts of radiation close to the floor, while radiation levels near the beams and the ceiling were 0.52 microsieverts and 0.72 microsieverts, respectively. Near the concrete roof tiles, radiation levels were at 1.74 microsieverts.

"Apparently the roof had been cleaned using high-pressure water cleaners, but that was as low as the radiation levels got," says Yamauchi. "To bring the roof's radiation levels down, there's probably no other way but to replace the roof. First and foremost, we must aim to bring indoor radiation levels to 0.05 microsieverts, which they were before the disaster unfolded, and thereby creating safety zones."

According to Yamauchi, just like what has happened with roofs, radioactive cesium has become stuck to asphalt on the road, concrete gutters and cobblestones, and high-pressure water cleaners can only do so much.

At a July 27 meeting of the House of Representatives Committee on Health, Labor and Welfare, Tatsuhiko Kodama, professor and director of the University of Tokyo's Radioisotope Center, denounced the government's handling of the nuclear crisis: "What is the Diet doing at a time when 70,000 people have had to leave their homes and are wandering around?"

He illustrated the gravity of the situation and the dire need for decontamination efforts, saying: "The amount of radioactive materials that have been released in the latest nuclear disaster, if converted to uranium, is the equivalent of 20 of the atomic bomb that was dropped on Hiroshima."

At a lecture held at the Japan National Press Club in Tokyo on Sept. 30, Kodama explained that radiation decontamination referred to isolation of radioactive materials in the environment to await its radioactive decay, and that the "radiation decontamination" that he had thus far conducted at kindergartens and other facilities in the Fukushima Prefecture city of Minamisoma were not enough. "The decontamination I've done is a type of emergency measure to protect children and pregnant women, and not true decontamination." He continued: "Permanent decontamination requires the knowledge and technology of experts and corporations, and a massive amount of funds. It must not become an interest-driven public project."

Kodama says that before his decontamination activities, a certain kindergarten in Minamisoma was found to have small hot spots, recording 33 microsieverts of radiation on the roof and 5 to 10 microsieverts under a slide. While radiation levels can be lowered by around 50 percent after a single

decontamination session, Kodama says that it's difficult to bring roof radiation levels down to 0.5 microsieverts or lower.

"To take the next step, we need the cooperation of house builders to determine whether a roof's surface should be scraped off or the roof in its entirety should be replaced, depending on the materials used," says Kodama.

Meanwhile, because replacing roofs will inevitably result in more radioactive waste, Kyoto Seika professor Yamada and his project team are collaborating with a house manufacturer to create cloth-like adhesive stickers that would be affixed to roofs and peeled off to remove just the radiation-contaminated surface.

According to the Basic Policy for Emergency Response on Decontamination Work released by the government's Nuclear Response Emergency Headquarters on Aug. 26, the government has set a provisional goal for the next two years to reduce yearly radiation exposure by 50 percent (60 percent for children). In setting this goal, the government presupposes that natural phenomena such as physical attenuation and weathering will decrease radiation exposure by 40 percent in two years, and that the remaining 10 percent (20 percent for children) will come from decontamination activities.

"What residents want is not half the exposure to radiation," says Yamada. "What they want is for a return to levels that allow them to live with peace of mind. Massive amounts of radioactive materials have been spread across wide areas in the ongoing disaster, so we can't count on the weathering effect. There's also the possibility that radiation will not only spread, but will start to accumulate in large concentrations in certain places. The half life of cesium 137 is approximately 30 years, but that of cesium 134 is 2 years. What the government has said is the equivalent of saying that they won't engage in full-fledged decontamination activities."

Both Yamada and Yamauchi agree that children and pregnant women living in areas that have not been subject to evacuation orders but have nonetheless been found to have high levels of radiation -- like the cities of Fukushima and Koriyama -- should be evacuated temporarily, and that those areas be thoroughly decontaminated while those populations are away. Kodama also says that residents living in areas with yearly radiation exposure of 1 millisievert or higher who want to evacuate should be fully supported by the government and Tokyo Electric Power Co., the operator of the stricken power plant.

Kodama finishes his book, "Naibu hibaku no shinjitu" (The Truth about Internal Exposure), with the following: "We have contaminated our country's earth, this irreplaceable inheritance from our ancestors that we had been charged with and must pass on to our children. However, if humans are the ones who contaminated it, then we humans should be able to clean it up again."

With challenges such as the designation of temporary radioactive waste dumps and interim storage facilities yet unsolved, the road to true decontamination remains a long one.

New safety rules for outdoor nuclear workers

Japan's health ministry will introduce safety guidelines to protect workers who clean up radioactive substances around the disabled Fukushima Daiichi nuclear power plant.

Existing guidelines target only those working indoors at the plant.

Citizens groups had complained that the ministry was not doing enough to minimize the exposure of workers who engage in decontamination outdoors.

The new guidelines will require outdoor clean-up workers to wear protective masks and carry dosimeters to monitor radiation.

The ministry says it will work to ensure that the rules are upheld, as efforts to decontaminate farmland and residential areas near the Daiichi plant will soon begin in earnest.

Friday, October 07, 2011 16:45 +0900 (JST)

TEPCO starts sprinkling decontaminated water

The Tokyo Electric Power Company, or TEPCO, has started sprinkling decontaminated water on the premises of the Fukushima nuclear power plant.

TEPCO on Friday began spraying the water onto trees cut down and piled on the plant's compound. The utility says dry trees could catch fire spontaneously.

The water was taken from facilities for temporary storage of water with low levels of radioactivity that had accumulated in the basements of 2 reactor turbine buildings. The buildings did not incur major damage in the March disaster.

The facilities contain about 17,000 tons of such water, and are filled to nearly 90 percent of their capacity.

TEPCO removed salt and radioactive substances from the water before the sprinkling process, and says levels of cesium and other radioactive substances in the water are below government standards for public beaches.

The company also says local communities and fishery associations approved the operation.

TEPCO plans to release 100 tons of decontaminated water daily on about 1.2 million square meters of land in the compound.

Removal of hydrogen starts at Fukushima plant

The operator of the troubled Fukushima Daiichi nuclear power plant on Saturday afternoon began to remove hydrogen that has built up in pipes connected to the No.1 reactor.

Tokyo Electric Power Company, or TEPCO, last month found that the level of hydrogen inside pipes connected to the No.1 reactor containment vessel accounted for between 61 and 63 percent of the total gas present.

TEPCO says an explosion is unlikely as there is no oxygen in the pipes now.

It adds that Saturday's work will not pose any risk of explosion as nitrogen is to be injected into the pipes to lower hydrogen levels.

TEPCO explains that it will use special hoses that do not generate static electricity to prevent an explosion while releasing hydrogen outside the reactor building.

Following a government instruction, TEPCO is planning to check the level of hydrogen in pipes linked to the No.2 and No.3 reactors.

Saturday, October 08, 2011 13:22 +0900 (JST)

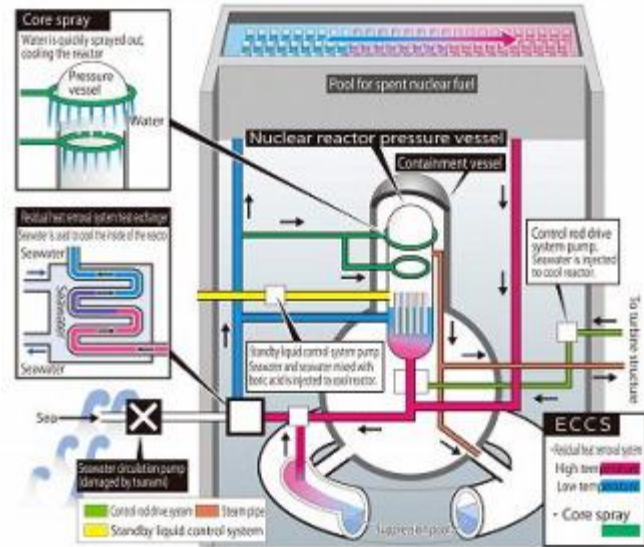

TEPCO starts to eject dense hydrogen from Fukushima reactor pipe

TOKYO (Kyodo) -- Tokyo Electric Power Co., the operator of the crisis-hit Fukushima Daiichi nuclear plant, said Saturday it has started to discharge hydrogen with high concentration levels from a pipe connected to a reactor containment vessel at the plant, as a measure to prevent an explosion.

The utility said it has injected nitrogen into the pipe for the No. 1 reactor vessel to **eject hydrogen found with high density of over 60 percent. The hydrogen has been generated by radiation that dissolved water.**

TEPCO said it will make sure that the concentration level of hydrogen is lowered to less than 1 percent before removing the pipe and going ahead with a plan to connect a system to clean up radioactive materials in the vessel.

Layout of cooling systems at Fukushima No. 1 nuclear power plant

Layout of cooling systems at the Fukushima No. 1 Nuclear Power Plant. (Mainichi)

While TEPCO said a hydrogen explosion is not expected to occur in the pipe in a lack of oxygen, it has decided to lower the level of concentration to prevent an explosion from occurring during the work to cut off the pipe.

The utility plans to check the levels of hydrogen in the pipes at the plant's Nos. 2 and 3 reactors which were also damaged in the crisis that caused radiation leakage.

(Mainichi Japan) October 8, 2011

Removal of hydrogen continues at Fukushima plant

Tokyo Electric Power Company will try to remove more hydrogen from the troubled Fukushima Daiichi nuclear power plant on Sunday. The density of the gas increased in pipes connected to the No. 1 reactor after a significant drop on Saturday.

Last month, TEPCO found that hydrogen had built up inside pipes leading to the No. 1 reactor containment vessel and its density was between 61 and 63 percent of the total gas present.

This poses a problem because releasing high densities of hydrogen outside the reactor building could cause another explosion.

On Saturday, TEPCO spent one hour removing hydrogen, while at the same time injecting nitrogen to the pipes to reduce the risk of an explosion.

About half an hour later, the company found the percentage of hydrogen had dropped to nearly zero.

However 2 hours later, the density was measured at 3.9 percent. Even though TEPCO says an explosion is unlikely, **hydrogen at a density of over 4 percent could cause a blast when mixed with**

oxygen.

TEPCO believes that the hydrogen level rose because gas accumulated in the upper part of the pipes may have redistributed internally.

Sunday, October 09, 2011 08:58 +0900 (JST)

Temperatures drop at Fukushima damaged reactors

New footage of the troubled Fukushima Daiichi plant has been released by the Tokyo Electric Power Company. No steam is seen leaving the No.2 and 3 reactors, which indicates that internal temperatures have dropped.

On Saturday TEPCO released video footage taken from above the No. 1 through No. 3 reactor buildings between Monday and Thursday.

As for the No. 1 reactor building, a hydrogen explosion collapsed its roof, blocking a clear view of the inside.

The video shows that the No. 2 reactor building suffered no major damage to its pipes and other equipment.

However, inside the No. 3 reactor building debris are scattered everywhere.

TEPCO confirmed that no steam is presently being released from reactors No.2 and 3. In August, the 2 reactors were emitting steam.

Officials say the temperature inside the No. 3 reactor dropped below 100 degrees Celsius 3 weeks ago, followed by a decline in temperature at reactor No.2.

TEPCO believes that the drop in temperatures has led to the reduction in steam.

Photos of the central control rooms for No. 1 and 2 reactors were also released.

The maximum radiation level in the control rooms is 0.01 millisieverts per hour.

Sunday, October 09, 2011 08:58 +0900 (JST)

IAEA radiation team arrives in Fukushima

A team of radiation experts from the International Atomic Energy Agency has visited Fukushima Prefecture to exchange views with members of the Japanese government decontamination task force.

The 12-member IAEA team has been in Japan since Friday to give advice on ways to effectively clean up radioactive substances, at the request of Environment Minister Goshi Hosono.

The team includes IAEA experts on radiation protection and radioactive waste as well as Russian experts with knowledge of the 1986 Chernobyl accident.

The team arrived in the prefecture on Sunday morning and exchanged views with prefectural officials and members of the government decontamination task force.

The head of the Japanese task force, Masaru Moriya, said it is essential to make living space safe through decontamination, as tens of thousands of people are still living in shelters.

Moriya said he hopes members of the IAEA team will give advice from a technical viewpoint based on their knowledge of and experience in decontamination.

The IAEA team's leader, Juan Carlos Lentijo, said the team will inspect demonstration experiments for decontamination and try to make a useful report to Japan and the rest of the world. Lentijo is general director at Spain's nuclear regulatory authority.

The team will later visit Minami Soma City to inspect areas for the government's model decontamination projects. For the remaining 2 days, the team will also visit Date City and Iitate Village.

Sunday, October 09, 2011 13:03 +0900 (JST)

Thyroid checkups begin for Fukushima children

The Fukushima prefectural government has begun thyroid examinations for children in an effort to assess the health impact of the nuclear accident.

The examinations will cover around 360,000 youths aged 18 or younger as of April 1st.

Their health will be monitored for their lifetime. Radioactive iodine released from the damaged nuclear plant could accumulate in children's thyroid glands, raising the possibility of cancer.

On Sunday, 150 children from some municipalities in the government-designated evacuation zone, such as Iitate Village and the Yamakiya district of Kawamata town, underwent ultrasound examinations for tumors or other problems at Fukushima Medical University.

The results are expected to be mailed to them in about a month.

The prefectural government says it plans to **have all the children examined by 2014.**

After that, it says the children will undergo a thyroid check every 2 years until they turn 20, and will be examined once every 5 years after that age.

Sunday, October 09, 2011 12:49 +0900 (JST)

Farmers frustrated on removing tainted straw

The Yomiuri Shimbun

MORIOKA--Livestock farmers in three disaster-hit prefectures in the Tohoku region are having difficulty disposing of rice straw contaminated with radioactive cesium from the Fukushima No. 1 nuclear power plant.

Cattle farmers are complaining that the central and local governments have not decided how to get rid of the contaminated straw.

"We have no space to store new straw, even though the rice harvest season has started. We want the government to remove the contaminated straw as soon as possible," one farmer said.

More than 600 bales of straw sat in one greenhouse at a cattle farm in southern Iwate Prefecture. Their combined weight was more than 60 tons, the farmer said.

Radioactive cesium of more than 8,000 becquerels per kilogram was detected in the straw, more than the limit allowed for incinerating the straw or taking it to a landfill.

A woman at the farm said in bewilderment, "How long will this situation continue?"

According to the Iwate prefectural government, 230 cattle farms in 23 municipalities in the prefecture are storing a total of 700 tons of contaminated straw.

In August, the Agriculture, Forestry and Fisheries Ministry announced interim measures to deal with contaminated straw. According to the policy, straw contaminated with cesium of more than 8,000 becquerels per kilogram should be stored temporarily on farmers' land or public land by covering it with sheets. Straw contaminated with cesium of 8,000 becquerels or less should be incinerated or sent to landfills as general waste by municipalities.

Municipalities in the prefecture preferred sending straw with lower levels of cesium to landfills, because it would be difficult to get residents worried about scattered ash to agree to incineration.

But the Environment Ministry is recommending against such a measure. According to a spokesman, "It's unrealistic to put the straw in landfills, given the massive amount. It might produce gas and result in a fire."

However, incineration would involve a different problem. Radioactive cesium might be condensed in the ash, making it difficult for municipalities to store ash contaminated with cesium beyond the government-set limit.

The prefectural government decided at the end of August to fully subsidize municipalities' expenses for disposing of contaminated straw. However, **concrete methods for disposal remain undecided.**

Shigemi Takaizumi, chairman of a commercial cattle production organization in Ichinoseki, Iwate Prefecture, comprising 28 cattle farmers, said: "It will snow in a month. If the contaminated straw isn't removed by then, we can't store this year's straw."

Takaizumi, 60, said cattle farmers who have a large amount of contaminated straw have to rent land to store new straw or leave the new straw outside.

In Miyagi Prefecture, about 4,700 tons of contaminated straw is being stored by livestock farmers and straw dealers in 22 municipalities, according to the prefectural government.

The prefectural government plans to keep the straw at temporary storage sites to be set up in collaboration with municipalities.

According to government projection, a total of 35,000 square meters of storage space will be needed. Municipalities are in the process of selecting suitable sites. The contaminated straw will be incinerated after temporary storage, but the time and place for incineration have yet to be decided, the government said.

In Fukushima Prefecture, 143 livestock farmers currently store contaminated straw. The prefectural government instructed them to separate contaminated straw from ordinary straw by covering contaminated straw with sheets or coloring it with a spray.

The prefectural government plans to deal with straw contaminated with cesium of over 8,000 becquerels after the central government decides on a disposal method.

(Oct. 9, 2011)

Nuclear stress test survey

An NHK survey shows that more than 40 percent of the country's prefectures and municipalities hosting nuclear power plants approve of the government's stress tests to confirm the safety of idle nuclear reactors. But nearly 80 percent were cautious about resuming their operation.

NHK received survey replies from all 29 prefectures and their municipalities that host nuclear power plants, excluding Fukushima Prefecture, in late September.

41 percent of them approved of the tests, while 14 percent disapproved. 45 percent were undecided.

But 79 percent of the prefectures and municipalities said they want to be careful about the timing of resuming operations at their idle reactors.

The results are similar to a survey taken in June before the introduction of the stress tests, indicating that the tests have not helped to win the public's understanding toward resuming operations.

Meanwhile, 2 villages said they want to resume operations at their nuclear reactors as soon as possible. These were part of the 21 percent in favor of continuing nuclear power generation.

A Nuclear and Industrial Safety Agency official said nuclear experts will examine the stress-test results

and publish the information. The official added that he will make sincere efforts to explain the tests to local residents.

Sunday, October 09, 2011 22:37 +0900 (JST)

Hosono: transparent stress tests

Japan's minister in charge of the nuclear disaster says the results of the government's stress tests on nuclear reactors will be fully disclosed.

In a speech in Sanjo City, Niigata Prefecture, on Sunday, Goshi Hosono said he told IAEA Director General Yukiya Amano in Vienna that he would like the agency to observe the tests.

He said that although the Japanese government is responsible for securing the safety of the nation's nuclear plants, he also wants international evaluations.

Hosono said he will disclose the results of the tests to the municipalities and residents concerned, and make the testing process highly transparent.

Sunday, October 09, 2011 22:37 +0900 (JST)

Tokyo under illusion that things are normal while Fukushima remains a war zone

We are well into autumn. And despite the growing sense in the Tokyo metropolitan area that things are now all right -- with train services back to pre-disaster schedules and the regret we once felt over our wasteful consumption of electricity dissipating -- Fukushima remains a war zone.

It was reported on Oct. 7 that the Watari district of Fukushima was not designated by the government as a "specific evacuation recommendation spot."

The following day, at an information session held for local residents at Watari Elementary School, participants demanded to know why their district was excluded from the list when it was a dangerous place for children to be, to which a government official responded: "It's not a final decision."

While this battle was taking place, I went to visit Watari residents Chieko Tanji, 64, and her husband, Hiroshi, 63, to hear about their personal battles with radiation and decontamination.

Once a week, the couple, who run a cafe in the district, put on long-sleeved work clothes and 3M-Sumitomo dust masks to scan their property for high levels of radiation, using a U.S.-made Geiger counter and a Chinese-made radiation dosimeter.

The Tanjis often find high radiation levels under the gutters, and scrape off any accumulated dirt and dust. They climb onto the roof, which they sweep with a broom, and remove the trash and leaves that have collected in the gutters. They also diligently trim the greenery in their yard that prior to the nuclear disaster, they'd allowed to grow freely.

"We wish we could count on the government to do something, but we've realized that we can't wait for their instructions. We have to listen to what other people have to say, do our own research, and make our own decisions," Hiroshi said. "I think it'll take 100 years before everything is clean again. At the moment, it's more like we're pursuing the possibility of decontamination than actually undertaking decontamination, but we're putting our faith in the possibility, even if it's just 1 percent."

I'd worked in Fukushima in the past, which was when I came into contact with the Tanjis. But that was already 17 years ago, and it was only through the newly released book, "Chronicle Fukushima," that I learned about what happened to them after the triple disasters of March 11.

The book is a record of lectures on the nuclear disaster and seven interviews, including one with the Tanji family. Guitarist and composer Yoshihide Otomo, 52, who has composed music for films and television dramas both in Japan and abroad, served as lecturer and interviewer. Having spent his youth in Watari, Otomo's emotional attachment to the area comes through crystal clear in the book.

As it turned out, the Tanji family had been torn apart. The book provides a vivid account of the Tanjis sending their son's wife and child off to Nagoya on March 14, just before the explosions at the nuclear power plant that spread radioactive materials far and wide.

Among the others who appear in the book is Shinzo Kimura, 44, a radiation hygiene expert who resigned from his post at a research institute under the jurisdiction of the Ministry of Health, Labor and Welfare when it prohibited an initial investigation into the disaster, and immediately went to work in the disaster area. Also appearing in the book is award-winning poet and Fukushima resident Ryoichi Wago, 43, whose Tweet: "It's raining radiation. It's a quiet night," received a massive response.

The interviews are all directed at Tokyo. The core message is summed up by Otomo, who says: "Come here and look at the reality."

Watari first took the spotlight when 24 times the radiation level permitted in school playgrounds by the central government was found in a daycare playground there in May. Just last week, reports emerged of there being 300,000 becquerels of radioactive cesium per kilogram of soil in the district. This figure, too, far exceeds the maximum permissible amount set by the government.

The persimmons growing in front of the Tanjis' cafe, Fu to boku (wind and trees), have turned orange. There's been an unusual abundance of the fruit this year, but they've been found to have 176 becquerels of radioactive cesium per kilogram. The light purple flowers that adorn a tabletop inside the cafe were picked by the couple in the Yamagata Prefecture city of Yonezawa.

Of utmost urgency now are the evacuation of children, decontamination, and the installation of becquerel monitors to measure radiation levels in food. But meanwhile, in Tokyo, we're talking about economic growth and the export of nuclear technology, as if what's going on in Fukushima is somehow irrelevant to us. That, I believe, is simply wrong. (By Takao Yamada, Expert Senior Writer)

City of Fukushima to decontaminate orchards on test basis

FUKUSHIMA -- The municipal government here is poised to conduct a test decontamination of local orchards tainted by radioactive substances leaking from the Fukushima No. 1 nuclear plant, officials said.

If the test run proves effective, it will work out a schedule for decontaminating farmlands and incorporate it in the city's overall decontamination plan. However, **finding enough space to store removed soil will likely pose a challenge.**

In the experiment, the municipal government will cooperate closely with local agricultural cooperatives to decontaminate **pear and peach orchards** in areas where radiation doses are high. **The city of Fukushima was ranked No. 1 nationally in the harvest of pears and No. 2 in peaches in 2006.**

After surveying the geographical features of the orchards, such as the degrees of their inclinations, workers will remove surface soil, tree bark and fallen leaves.

The city will not conduct the experiment in ordinary farmland because **most fields have been plowed since the disaster.**

The municipal government has not yet secured enough space to store removed soil. If a 5-centimeter layer of surface soil is removed from all the orchards in the city, it will generate about 1.2 million cubic meters of soil, enough to fill the Tokyo Dome baseball stadium.

Still, the municipal government will try its utmost to look for storage space.

"Decontamination is indispensable to ensure the safety and security of our food. We'll select space to store soil while gaining cooperation from local residents," a city official said.

Orchard owners in the city have mixed feelings about the city's plan.

One, Kiyoshi Sato, 65, owns an orchard covering about six hectares along National Route 13. He relies little on insecticide and mainly uses organic fertilizers.

"If a five-centimeter layer of surface soil is removed from ordinary farmland, it will lose a considerable amount of nutrition. I don't know whether it's also the case with orchards, but I fear decontamination could adversely affect my orchard," Sato said.

"However, if data shows the levels of radiation have decreased following decontamination, it will help prevent nasty rumors about our products, and we can be optimistic about the future. We must do whatever we can do," he added.

IAEA team in Japan; Fukushima starts thyroid tests

TOKYO (AP) -- Experts from the International Atomic Energy Agency arrived in the Japanese city of Fukushima on Sunday to observe the massive decontamination effort following the world's worst nuclear disaster since Chernobyl.

Local doctors also began a long-term survey of children for thyroid abnormalities, a problem associated with radiation exposure. Officials hope to test some 360,000 people who were under the age of 18 when the nuclear crisis began in March, and then provide follow-ups throughout their lifetimes.

The 12-member IAEA group was to visit farms, schools and government offices throughout Fukushima prefecture in northeastern Japan to observe the cleanup process. It is the U.N. atomic agency's second major mission to Japan since the crisis at Fukushima's Dai-ichi nuclear power plant began.

Nearly 20,000 people were killed when the earthquake and tsunami hit Japan on March 11, and the disaster severely damaged the Fukushima complex. Officials say the plant is now relatively stable, but tens of thousands of people still cannot -- or choose not to -- return to their homes because of the radioactive contamination.

No one has died from radiation in the nuclear crisis, but concerns remain high over how the lingering contamination will impact the safety of Fukushima's children.

The thyroid testing program is intended to allay those fears and build a database that might help deal with future disasters. On its opening day Sunday, more than 100 children, whose thyroid glands are more susceptible to radioactive iodine than adults, were checked.

The results were not made public, but officials have said that if any abnormalities are discovered, the children -- to be tested every two years until age 20, and then every five years after that -- will be provided with further care.

In this photo released by Tokyo Electric Power Co., a tent to cover Unit 1 reactor building is under construction at the crippled Fukushima Dai-ichi nuclear power plant in Okuma, Fukushima Prefecture, northeastern Japan, Saturday, Oct. 8, 2011. (AP Photo/Tokyo Electric Power Co.)

More than 6,000 cases of thyroid cancer have been detected in people who were children or adolescents when exposed to high levels of radioactive fallout in the period immediately after the 1986 Chernobyl disaster.

A 12-mile (20-kilometer) no-go zone remains in effect around the Fukushima nuclear plant. Japan recently lifted other advisories that warned residents just outside of that zone to be prepared to evacuate at any time, a move largely aimed at reassuring evacuees that it is safe to return.

To further bring down contamination levels, towns outside of the no-go zone have begun washing down public areas and removing the top soil in parks and schoolyards.

The task is a daunting one because the nuclear accident spread radiation unevenly over a broad swath of Fukushima, leaving some areas near the plant relatively safe, while creating dangerous hotspots farther away.

Japan's government has acknowledged that the effort could take years. According to a report Sunday in the Asahi, a major newspaper, officials are aiming to complete the decontamination outside of the exclusion zone by the end of March 2014.

(Mainichi Japan) October 10, 2011

Stress tests not likely nuclear safety criteria

An NHK survey shows that nearly 60 percent of the country's prefectures and municipalities hosting nuclear plants say it is important to gain the understanding of local communities to permit the resumption of idle reactors. But less than 20 percent say they will put priority on the results of the government's stress tests on nuclear reactors.

NHK received survey replies in late September from all 29 prefectures and their municipalities that host nuclear power plants. Fukushima Prefecture was not included in the survey.

41 percent approved of the stress tests, while 14 percent disapproved. 45 percent were undecided.

Even among those that approved, many said the government abruptly introduced the tests and that their contents have not been made clear.

Answering multiple-choice questions on what factors they consider important in deciding on restarting reactors, 59 percent cited **local consent** and 45 percent said **explanations from the government**. **Only 17 percent said the results of the stress test will be important.**

In July, the central government decided to carry out the new safety assessment in an effort to reassure residents.

Yoshinori Moriyama of the government's Nuclear and Industrial Safety Agency said his agency wants to make the testing process more open and explain the situation to local residents.

Hydrogen level falls at Fukushima plant

The operator of the troubled Fukushima Daiichi nuclear power plant says the level of hydrogen in a pipe at the No. 1 reactor has become **low enough to make an explosion unlikely**.

Tokyo Electric Power Company, or TEPCO, on Sunday finished removing hydrogen from inside a pipe connected to the reactor's containment vessel.

The utility had been injecting nitrogen into the pipe to remove hydrogen since Saturday.

Last month, the hydrogen levels inside the pipe were found to account for between 61 and 63 percent of the total gas present, posing a risk of explosion.

TEPCO says the hydrogen level is now low enough and even if it were to rise again, it would not exceed 4 percent -- the lowest level that poses a risk of explosion.

On Sunday evening, TEPCO cut 2 points of the pipe to allow the installation of a device that filters radioactive substances inside the containment vessel.

The cutting operation was about 2 weeks behind the schedule the company set for its plan to contain the nuclear accident at the plant.

TEPCO says it wants to install and start operating the device as early as possible.

Decontamination plan compiled

The Japanese Environment Ministry has come up with a revised plan to clear away radioactive substances from the crippled Fukushima Daiichi nuclear plant.

It announced details on Monday at a meeting of a panel of experts.

Ministry officials say decontamination will be **carried out in areas where radiation levels are higher than 1 millisievert per year**.

The ministry revised an earlier plan to only decontaminate places with more than 5 millisieverts per year. Municipalities in Fukushima Prefecture that have areas with less than 5 millisieverts argued they should be included in the cleanup.

The government will be responsible for the decontamination of no-entry zones and government-designated evacuation zones. Local governments will clean up the rest of the affected areas.

Areas with radiation levels higher than 20 millisieverts per year will be reduced stage by stage as soon as possible.

In areas with less than 20 millisieverts per year, radiation levels recorded at the end of August will be cut up to 60 per cent in the next 2 years.

Environment Ministry officials say the government will help prefectures that have a massive amount of radioactive waste.

The ministry's decontamination plan will be further discussed within the government before being adopted by the Cabinet as the basic national plan.

Monday, October 10, 2011 22:04 +0900 (JST)

IAEA team chief welcomes Japan's handling of decontamination waste

FUKUSHIMA, Japan (Kyodo) -- The head of a team of experts from the International Atomic Energy Agency on Tuesday hailed Japan's efforts in ensuring the safe handling and management of waste from the cleanup of radiation-tainted areas near the crippled Fukushima Daiichi nuclear power plant.

In talks with Fukushima Gov. Yuhei Sato, Juan Carlos Lentijo, general director for radiation protection at Spain's nuclear regulatory authority, also said the 12-member team has had meaningful discussions with Japanese officials during their visit to advise on the decontamination work.

Meanwhile, Sato told Lentijo, "Decontamination is most important in order for our residents to resume their daily lives. It is the first time for Japan to conduct decontamination over such an extensive area and taking this opportunity, I hope to ask for (the IAEA's) continued support for Fukushima for many years to come."

The IAEA team, which arrived in Japan on Friday, is scheduled to head to Tokyo later on Tuesday after visiting the Fukushima Daiichi plant.

The experts will stay in Japan until Saturday and present a preliminary report to the Japanese government at the end of their mission.

Tuesday's meeting coincided with the seven-month anniversary of the March 11 earthquake and ensuing tsunami that crippled the Fukushima plant.

(Mainichi Japan) October 11, 2011

Govt reviews nuclear power generation costs

Japan's Atomic Energy Commission is creating a new estimate of the cost of nuclear power as part of a review of the country's nuclear policy.

For the first time, it will take into account the **cost of compensation for possible nuclear accidents.**

The review of Japan's policy on nuclear power use, research and development had been suspended after the accident at the Fukushima Daiichi nuclear plant in March. It resumed last month.

A subcommittee tasked with calculating the cost of nuclear power was set up by the commission on Tuesday.

Acting commission head **Tatsujiro Suzuki** said it will be the first cost assessment since the Fukushima accident, and will gain attention both at home and abroad.

He said he hopes to conduct an **objective** estimate in which the data as well as premises and procedures of the calculation are **transparent.**

The subcommittee will calculate the cost of recycling spent nuclear fuel by extracting plutonium, a main pillar of the current nuclear policy. It will estimate the cost of discarding it as waste as well.

It will also debate how far to include the costs of compensation, decontamination and reactor decommissioning after nuclear accidents.

While the commission plans to release its overall cost estimates by March, projections for the costs of accidents will be submitted to a government panel now reviewing Japan's energy policy before the end of this month.

Tuesday, October 11, 2011 12:55 +0900 (JST)

Residents near Fukushima mountains face nuclear recontamination every rainfall

As the crisis at the Fukushima No. 1 Nuclear Plant drags on, worries are growing particularly among Fukushima Prefecture residents over drawn-out and in some cases apparently futile nuclear decontamination operations.

The unease is especially strong in areas in and around mountains that must be repeatedly decontaminated, as **every rainfall brings a new batch of radioactive substance-contaminated leaves and soil washing down from the hills.** Since some 70 percent of Fukushima Prefecture is mountainous, such instances of regular recontamination could occur over a broad area, while the same effect has also been observed in some undeveloped areas of cities.

The central government is considering paying for any decontamination operations conducted by local governments at sites with radiation emissions of 1 millisievert per year or more, but residents in places faced with regular recontamination after every major rainfall are concerned the national government may not keep the cleanup funding flowing.

The city of Fukushima decontaminated its Onami and Watari district in July and August after a surge in local radiation levels. In the week following the end of the operation, the city took fresh radiation readings at 885 points, of which seven actually registered levels exceeding those found before the

decontamination. One gutter measured even showed a rise from 3.67 microsieverts per hour before the cleanup to 4.63 after the work.

"Radiation increased close to the mountains and in spots where water and soil washed down the slopes," the Fukushima Municipal Government stated.

One 52-year-old resident of the city's Onami district, whose home backs onto woodland slopes, told the Mainichi that soil washes into her backyard with every rainfall. Radiation emissions at her front door are 1 microsievert per hour or less, but in the backyard they're more than 2 microsieverts per hour.

"Everywhere around here is in the same situation," she says.

Meanwhile, a man living in the Watari district with his wife and his son's family discovered that the waterway running by his property had cesium levels of more than 300,000 becquerels after a citizen's group did tests in the area.

"There's no point in doing just one round of official decontamination," he told the Mainichi. "We residents will get nowhere near anything like peace of mind if decontamination operations can't be done regularly."

According to guidelines in a Ministry of Agriculture, Forestry and Fisheries study released on Sept. 30, removing fallen leaves and other natural forest debris from the area within about 20 meters of residential properties is effective in keeping contamination at bay. However, the guidelines also warn that "conifer needles also accumulate radioactive cesium over time, and can normally be expected to fall after three to four years," signaling a **constant and long-term need to keep clearing properties of fallen needles.**

The municipality of Fukushima has created a plan to bring radiation exposure in all inhabited areas of the city to below a microsievert per hour within two years. As part of this, cleanup operations will begin in the Onami district in October. No schedule has been set for decontaminating the city's mountains and forests, but the municipal government is considering removal of the leaf soil (soil made up of decaying leaves) within 75 meters of local properties, pending the consent of land owners -- significantly more than the forestry ministry's 20-meter guideline. It's thought that the decontamination process will have to go on for a long time to come, but **the city has said it has yet to receive confirmation that financial support will continue to flow from the central government.**

Furthermore, the problem of where to put all the contaminated material collected in the cleanups remains a serious headache. The central government has begun considering national forests as dump sites, but according to a disposal official in Date, Fukushima Prefecture, "'20 meters of forest' applied to every region here would be an enormous amount of material. Setting aside a site for that much soil is extremely difficult. On top of that, **how could we secure enough workers to do the job?**"

On top of concerns about the sheer volume of contaminated material and manpower, there is also the issue of the important natural roles played by forests, such as collecting water that eventually ends up as well water. The village of Kawauchi, removed from the emergency evacuation standby zone at the end of September, is almost 90 percent mountain forest, and depends on streams and well water for all its fresh water needs.

The village plans to decontaminate all the forest under its jurisdiction over the next 20 years, but "the village needs the forests to guarantee its source of fresh water," the decontamination project official said. "Is there no way to do decontamination while at the same time preserving the functions of the forest, without cutting down the trees?"

Gov't decontamination work to cover low-radiation areas

TOKYO (Kyod) -- The Environment Ministry has decided to widen the area covered by a government-funded decontamination project to those with a minimum annual radiation exposure of 1 millisievert in the aftermath of the Fukushima nuclear crisis, officials said Tuesday.

The ministry lowered the minimum annual radiation exposure level from the previous 5 millisieverts in the face of calls by local governments.

The policy change is aimed at decontaminating low-radiation areas frequented by children, such as schools, the officials said.

A government map displaying radiation levels in 10 prefectures relatively close to the Fukushima No. 1 Nuclear Power Plant. Areas in red show over 3 million becquerels of cesium per square meter, whereas those in light brown show less than 10,000. (Data as of Sept. 18. Image courtesy of the Ministry of Education, Culture, Sports, Science and Technology)

The latest decision also includes the government's responsibility to dispose of incineration ashes and sludge contaminated with radioactive cesium of more than 8,000 becquerels per kilogram.

The Cabinet will endorse a basic plan for decontamination in early November at the earliest, they said.

Under the envisioned plan the government will decontaminate relatively highly contaminated areas, such as no-go zones near the Fukushima Daiichi power plant that was crippled by the March 11 earthquake-tsunami disaster. Local governments will work out decontamination plans for other areas.

Workers measure the ground near a rain water outlet in Minamisoma, Fukushima Prefecture, on June 12.
(Mainichi)

The government will also try to reduce the annual exposure for adults by 50 percent and for children by 60 percent in two years through the end of August 2013 in areas with annual radiation at less than 20 millisieverts.

On the controversial issue of disposing of radiation-contaminated incineration ashes and sludge, the central government will do so in the prefectures where they accumulated, according to the basic plan.

(Mainichi Japan) October 11, 2011

Students return to Fukushima schools for first time since start of nuclear crisis

Students are seen at work on Oct. 11, the first day of school in their original school building since the beginning of the Fukushima nuclear crisis, in Iwaki, Fukushima Prefecture. (Mainichi)

IWAKI, Fukushima -- On Oct. 11, seven months after the earthquake and the beginning of the Fukushima nuclear crisis, students of three schools here returned to their classrooms for the first time since the disasters.

The schools, south of the stricken Fukushima No. 1 nuclear plant, had been part of the government-designated indoor advisory zone, and their reopening is the first for any schools within the indoor standby and evacuation zones.

One part of the Hisanohama district of the city where the schools are located is within 30 kilometers of the plant, and had been under an indoor advisory from the beginning of the disaster until April 22. One of the schools to reopen, Hisanohama No. 2 Elementary School, had been within this zone, while parts of the districts of Hisanohama No. 1 Elementary and Hisanohama Junior High School had also come under the zone. All the schools had been borrowing space from other schools in the center of the city, but decided to move back to their home buildings after decontamination efforts brought radiation levels on the ground and surrounding streets down significantly.

Many of the schools' students have already moved out of the prefecture, dropping student numbers. The 225 kids enrolled at Hisanohama No. 1 Elementary School before the disaster had dropped to about 190 on Oct. 11, many of whom were bussed to class from leased housing scattered across the city. Once there, however, the children appeared pleased to be back at their original schools.

"I'm happy to be back in this school, which is full of so many memories," said sixth grader Ryota Suzuki with a smile. Some parents, however, remain concerned.

"I'm still a little worried about radiation levels," said one 38-year-old woman who dropped off her two sons -- one in third grade and one in first -- by car in the morning.

Daycare center near Fukushima plant reopens

A daycare center some 20 kilometers from the Fukushima Daiichi nuclear power plant has reopened for the first time since the accident there in March.

18 children aged 2 months to 5 years arrived with their parents at the center in Minami Soma City, Fukushima Prefecture, on Tuesday.

The facility decided to reopen when the Japanese government lifted its evacuation advisory for the city on September 30th.

Before reopening, the center reportedly took decontamination measures such as removing topsoil from its playground.

The head of the center said parents are understandably worried about the effects of radiation, so he wants to continue efforts to ensure the children's safety.

Tuesday, October 11, 2011 16:37 +0900 (JST)

Radiation checking facility opens

A facility that allows consumers to check radiation levels of food and other items has opened near Tokyo.

On Tuesday, about 20 people including housewives brought rice, water and vegetables to the facility in Kashiwa City. The facility was started by a computer software firm owner.

Kashiwa is about 200 kilometers from the troubled Fukushima Daiichi nuclear power plant. Radiation levels higher than those in surrounding areas have been detected in the air in the city.

The customers received explanations from staff members while using radiation counters. Results were shown in about 20 minutes.

A woman in her 40s said she checked rice because she's worried about her child, and that she was relieved because no radioactive substances were detected.

The facility charges about 13 dollars per use of a counter that can detect more than 20 becquerels per kilogram, and about 50 dollars per measurement to an accuracy of over 10 becquerels. The prices are lower than those of other test facilities.

The owner plans to increase the number of counters from the current 6 to 8.

Tuesday, October 11, 2011 20:52 +0900 (JST)

Britain's nuclear facilities declared safe despite Fukushima alert

There were 38 areas where the industry and regulators could learn lessons from the Japanese disaster

By Steve Connor, Science Editor The Independent

Wednesday, 12 October 2011

Britain's chief nuclear inspector has found no significant safety weaknesses in the UK's nuclear facilities following his detailed analysis of the Fukushima disaster in Japan which led to a 20-km (12-mile) evacuation zone around the stricken Japanese reactors.

Mike Weightman, HM Chief Inspector of Nuclear Installations and head of the Office of Nuclear Regulation, said there were lessons to be learned from Fukushima but that the fundamental safety rules governing Britain's nuclear power facilities are still sound.

"I remain confident that nuclear facilities in the UK continue to be safe to operate and I remain confident in the robustness of the nuclear safety regime in the UK," Dr Weightman said.

"I remain confident that our UK nuclear facilities have no fundamental safety weaknesses. The Office for Nuclear Regulation already requires protection of nuclear sites against the worst-case scenarios that are predictable for the UK," he said.

"But we are not complacent. Our philosophy is one of continuous improvement. No matter how high our standards, the quest for improvement must never stop. We will ensure lessons are learned from Fukushima," he added.

A report by the chief inspector into the implications for the UK of the Japanese earthquake and tsunami last March found that there were 38 areas where the Government, industry and its regulators could learn safety lessons.

The reactors at Fukushima-1 safely shut down after the initial magnitude-9 earthquake on 11 March but the critical cooling system failed after a 14-metre tsunami later inundated the site.

"A magnitude-9 earthquake and the associated 14m-high tsunami, are far beyond the most extreme natural events that the UK would be expected to experience," the chief inspector's report says.

However, Paul Dorfman of Warwick University and a member of the academic group NuclearConsult, said that many of Britain's nuclear facilities are built near the coast and are vulnerable to flooding. Dr Dorfman said the chief inspector's statement saying that there are no fundamental safety weaknesses in UK nuclear facilities is a "clear abrogation of regulatory responsibility".

Noda vows safer use of nuclear energy in wake of Fukushima crisis

TOKYO (Kyodo) -- Prime Minister Yoshihiko Noda expressed his strong resolve in a message Tuesday to a nuclear disarmament campaign's meeting in California to boost safety over the civil use of nuclear energy in the wake of Japan's ongoing nuclear crisis at the Fukushima Daiichi power plant.

"Japan will share with the international community, with the maximum transparency, all the lessons to be learned from the (Fukushima) accident...and is determined to raise the safety of nuclear power generation to the highest level in the world," Noda said in the prepared message delivered at the Global Zero Summit in Simi Valley.

Noda's message, which is the first for a Japanese premier to a summit of the international nonpartisan campaign launched in 2008 for the abolition of nuclear arms, came as Japan continues to struggle with the aftermath of the nuclear disaster triggered by the March 11 powerful earthquake and tsunami.

In this March 11, 2011 photo released Monday, April 11, 2011 by Tokyo Electric Power Co.,(TEPCO), the access road at the compound of the Fukushima Dai-ichi nuclear power plant is flooded as tsunami hit the facility following a massive earthquake in Okuma town, Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.,)

Noda said his country bears the "responsibility to find a path toward a future of safer nuclear power," referring to the issue of safety as another challenge to global efforts on nuclear disarmament and nonproliferation along with eliminating the risks of nuclear materials and technologies being diverted to military use.

"Being the only country to have suffered from atomic bombings, Japan is particularly convinced that the tragic consequences of the use of nuclear weapons must never be repeated," Noda said on the first day of the two-day summit, referring to the 1945 U.S. atomic bombings of Hiroshima and Nagasaki.

He also renewed his country's pledge to stick to its three non-nuclear principles of not producing, possessing or allowing nuclear weapons on its territory.

Bearing in mind the uncertainties in the security of Northeast Asia, Japan is "resolved to take the lead on international disarmament and nonproliferation efforts in a realistic and incremental approach," Noda said.

With the originators including former Soviet President Mikhail Gorbachev, former U.S. President Jimmy Carter and former Japanese Foreign Minister Yoriko Kawaguchi, the Global Zero campaign has drawn the support of more than 120 former political and military leaders, according to the Japanese Foreign Ministry.

Its summit was previously held in February 2010 in Paris and in June this year in London.

(Mainichi Japan) October 12, 2011

Tokaimura mayor calls for scrapping Tokai No. 2 nuclear plant

TOKYO (Kyodo) -- The mayor of a village hosting the Tokai No. 2 nuclear power station in Ibaraki Prefecture told the central government on Tuesday that the plant should be scrapped because it is aging and located near an area where many people live, village officials said.

Tatsuya Murakami, the head of Tokaimura, said during a meeting with nuclear disaster minister Goshi Hosono in Tokyo that the plant does not meet location requirements because one million people live within a 30-kilometer radius.

"Shouldn't the plant be decommissioned?" he was quoted as saying. Murakami also noted the plant is located near Tokyo.

The Tokai No. 2 plant has one boiling water reactor which has been in operation since 1978. The reactor, capable of producing 1.1 million kilowatts of electricity, is currently undergoing a regular checkup.

Public distrust toward nuclear power has grown strong since the devastating March 11 earthquake and tsunami triggered a disaster at the Fukushima Daiichi nuclear plant, setting off the world's worst nuclear crisis in 25 years.

When the earthquake and tsunami hit eastern and northeastern Japan, the Tokai reactor shut down automatically. A nuclear crisis similar to the Fukushima Daiichi plant disaster also did not occur because the Tokai No. 2 plant has taken measures to counter tsunami waves.

In 1999, the country's first nuclear criticality accident occurred in Tokaimura, claiming the lives of two workers at a nuclear fuel processing plant. Residents living around the plant were ordered to evacuate at the time.

(Mainichi Japan) October 12, 2011

No-go zone soil to be moved in 2-1/2 yrs

The Yomiuri Shimbun

Soil contaminated with radioactive substances in the no-entry zone and the expanded evacuation zone around the crippled Fukushima No. 1 nuclear power plant will be removed by the end of March 2014, the Environment Ministry has announced.

According to a draft plan compiled by the ministry, the radioactive soil will be removed in 2-1/2 years--except from areas where the level of radioactive contamination is too high--and taken to temporary storage sites.

A draft of the ministry ordinance said the central government will take responsibility for disposing of incinerated ash and sludge, including from areas other than the two zones, if their level of radioactive cesium exceeds 8,000 becquerels per kilogram.

This means that **not only Fukushima Prefecture but also the whole Tohoku region and the Tokyo metropolitan area will be included in the ministry's plan.**

The government is expected to approve the basic policy on the disposal of contaminated soil at a Cabinet meeting in early November.

The ministry gave the March 2014 deadline only to the no-entry and expanded evacuation zones. The decontamination work aims to reduce annual radiation count in the areas to less than 20 millisieverts, a senior ministry official said.

However, the ministry has not set any concrete target level or deadline for places where radiation counts remain too high to conduct decontamination work. The basic policy draft only says the ministry will try to determine effective measures by carrying out model projects in this regard.

The ministry set a long-term target of lowering the radioactive contamination level to 1 millisievert or lower annually in all areas, including the no-entry and expanded evacuation zone. The government will be responsible for decontaminating all these areas, it said.

Earlier, the ministry told local governments in Fukushima Prefecture that the government will be fully responsible for decontamination in areas with 5 millisieverts or higher, but partially responsible in areas with between 1 and less than 5 millisieverts.

The announcement sparked fierce opposition from the local governments.

The draft said the government will be responsible for securing interim storage facilities, where soil and sludge will be kept before final disposal, and final disposal sites where the soil and sludge will be permanently buried.

The basic policy draft was compiled based on the special measures law on handling environmental pollution caused by radioactive substances, which was established in August.

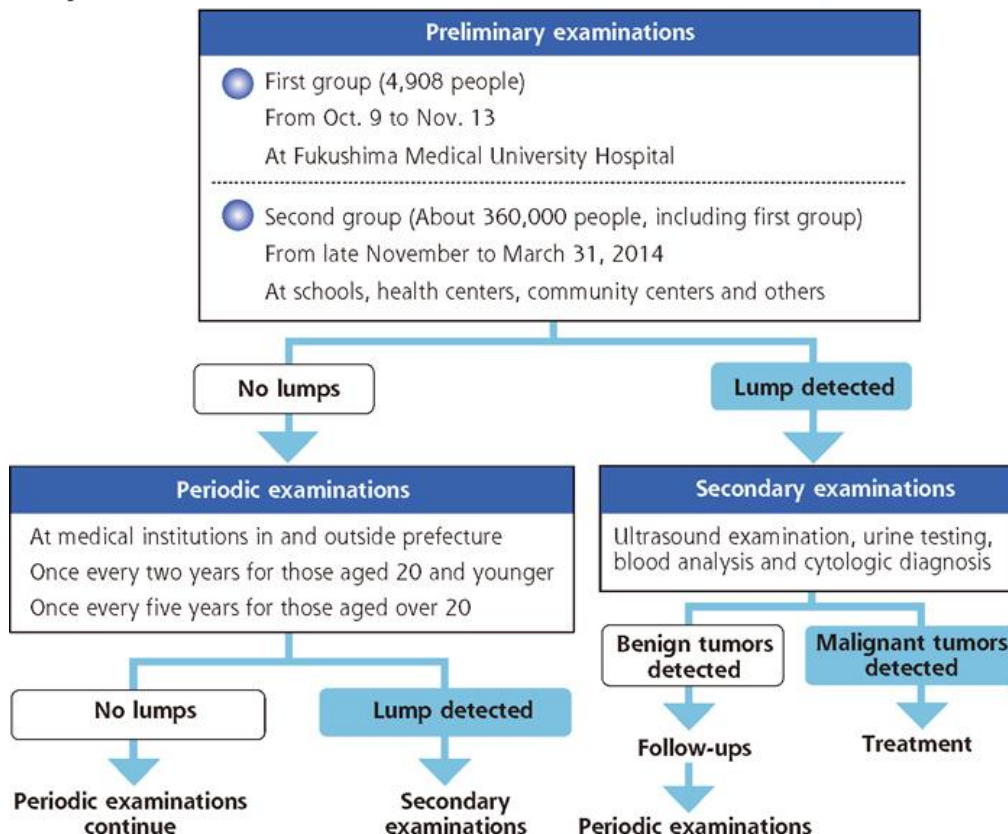

After gaining Cabinet approval, the basic policy is scheduled to come into force in January. The policy will be applicable retrospectively for local governments that have been conducting decontamination and disposal work. To promote decontamination over a wide area, the ministry has demanded 1.15 trillion yen for fiscal 2011-13, including funds in a not-yet-compiled third supplementary budget for this fiscal year.

Fukushima govt aims to ease parents' anxiety / Prefecture underlines its intention to monitor affected children's health throughout their lives

Sho Funakoshi and Makiko Tatebayashi / Yomiuri Shimbun Staff Writers

Thyroid examinations for children in Fukushima Prefecture

FUKUSHIMA--The Fukushima prefectural government has started carrying out thyroid examinations on all people aged under 19 in the prefecture--a total of 360,000 children and young people--because it took very seriously parents' anxieties over the effect of the nuclear crisis on their children's health.

The scale of the thyroid examinations is unprecedented in history, according to sources. The prefectural government has to overcome many hurdles, such as securing enough qualified doctors and preparing examinations for children evacuated to other prefectures because of the accident at the Fukushima No. 1 nuclear power plant.

On Sunday, 144 children from Kawamatamachi's Yamakiya district, as well as Namiemachi and Iitatemura, which are all areas designated as no-entry zones or expanded evacuation zones, underwent thyroid examinations. **The tests will be conducted periodically throughout the lives of those concerned,** according to the prefectural government.

A 16-year-old girl from Iitatemura said she is now staying in a Kawamatamachi district outside the zones. After taking the examination, she said, "I feel a bit better now as I was about to go crazy with the worry of getting cancer at some point in the future [because of radioactive material from the nuclear plant]."

However, she added, "I'm scared about finding out the results."

About 200,000 people underwent group examinations after the 1986 Chernobyl disaster in Ukraine. However, those affected were required to undergo only one examination. An official of the prefectural government's Finance Department said, "Our examinations will be unprecedented in terms of the number of years they will cover and the amount they will cost."

The prefectural government will secure a budget for the thyroid examinations from the central government's subsidy paid into its fund for health care projects. The prefectural government estimates that it will cost about 250 million yen in fiscal 2011.

The 4,908 children from the Yamakiya district, as well as Namiemachi and Iitatemura will undergo the thyroid examinations before children from other areas in the prefecture. The preliminary examinations will run until Nov. 13 at Fukushima Medical University Hospital in Fukushima city.

===

More doctors needed

About 30 doctors from the university, including thyroid specialists and pediatricists, will be in charge of the examinations. The average length of the thyroid in adults is about five centimeters. To diagnose children's thyroids, which are smaller than those of adults, doctors must have special knowledge and skills, the prefectural government said.

Children in other areas of the prefecture will be subject to examinations from late November, and these examinations will also take place at schools and community centers. Fukushima Medical University says it needs to double the number of doctors to examine all the children in the prefecture. The university has asked the Japanese Society of Thyroid Surgery and the Japan Endocrine Society to

dispatch doctors to the prefecture. At the same time, the university will host training sessions to nurture thyroid specialists, it said.

More than 10,000 people have been evacuated from the prefecture since the nuclear accident in March. The prefectural government said it plans to **establish at least one center in every prefecture where evacuees can take their children to have the thyroid examination.**

According to the prefectural government, it is sometimes difficult to find out the new addresses of children below school age, unlike high school, middle and primary school students whose new addresses can be obtained by making inquiries to their former schools. A Fukushima Medical University official in charge of the examinations said the university and the prefectural government will need the help of local governments and hospitals in areas to which evacuees have moved to tell them to take their children for examinations.

The prefectural government's section charged with managing and studying the health of citizens in the wake of the nuclear accident said, "The main purpose of the thyroid examinations is to allay the anxieties of parents as much as possible."

The prefectural government had received more than 20,000 inquiries from citizens about radiation as of August. About 40 percent of the inquiries were related to the impact of radiation on health, the government said.

The official who dealt with the inquiries said the phone in his office just kept ringing. Some parents told him they were unable to give their children iodine tablets that prevents radioactive iodine from building up in the body, and wanted to know whether their children would be safe.

According to a senior official of the prefectural government, the government had initially planned to start thyroid examinations in 2014, as it takes time for symptoms to appear in the thyroid, and also because of the damage caused to the prefecture's medical institutions by the March 11 disaster. However, the government brought the start date forward due to growing fears of parents over the health of their children, the official said.

One medical expert cast doubt on the effectiveness of the prefectural government's examination, saying: "There are areas where the radiation level is low. I don't see the need to carry out simultaneous thyroid examinations on 360,000 children."

Fukushima Medical University Vice President Shunichi Yamashita, who also serves as the president of the Japan Thyroid Association, stressed the significance of the examinations. **"This [the examinations] is a message that states the prefecture's intention to protect the children's health throughout their lives,"** he said.

(Oct. 12, 2011)

Thyroid cancer in Chernobyl

The Yomiuri Shimbun

Location of thyroid gland

Several years after the 1986 disaster at the Chernobyl nuclear power plant in Ukraine, the incidence of thyroid cancer rose among local children. Local authorities have recognized only thyroid cancer as being caused by the nuclear accident.

The butterfly-shaped thyroid gland is located just below the Adam's apple and is attached to the trachea. The thyroid gland produces thyroid hormone by absorbing iodine, which is contained in foods such as kombu seaweed.

If a person breathes in or absorbs radioactive iodine through food and drink, 10 to 30 percent of this iodine is said to accumulate in the thyroid.

From about five years after the Chernobyl accident, an increasing number of children began to develop thyroid cancer. It is believed they fell ill because they consumed milk and other food contaminated with radioactive material.

Before the accident, the chance of a child living in the vicinity of the nuclear power plant developing thyroid cancer was about one in a million per year. After the accident, however, at one point this incidence increased 100 fold--to about one in 10,000--in some areas.

According to surveys conducted by the United Nations and other organizations, 6,848 local residents who were younger than 18 years old at the time of the Chernobyl accident developed thyroid cancer over the 15 years from 1991 through 2005, of whom 15 were confirmed to have died.

On the other hand, it is unclear whether adults have suffered from radioactive contamination of their thyroids, as there has been no apparent increase in the incidence of thyroid cancer among them.

However, some grown-ups who were exposed to radioactive material as children at the time of the accident have developed thyroid cancer.

Because it is difficult to estimate how much radioactive material each resident was exposed to after the accident, experts are unable to agree on the level of exposure that would cause people to develop thyroid cancer.

It is highly possible, therefore, that follow-up examinations of people affected by Chernobyl may yet reveal adverse effects.

In the case of the accident at the Fukushima No. 1 nuclear power plant, Prof. Shinichi Suzuki of Fukushima Medical University believes there is "a low probability" that local children will develop thyroid cancer.

He cites restrictions being issued on drinking locally produced milk and tap water soon after they were found to have been contaminated with radioactive material beyond regulated standards as one factor supporting his views.

Suzuki's opinion is shared by Minoru Kamata, director emeritus at Suwa Central Hospital in Chino, Nagano Prefecture, who offered medical assistance in 1991 in areas hit by the Chernobyl accident.

"However, those children who were outdoors just after the nuclear accident [at the Fukushima plant] will need to be checked for possible adverse reactions," he said.

Tatsuhiko Kodama, head of the University of Tokyo's Radioisotope Center, said it took 20 years for experts to prove that the Chernobyl accident caused the increase in thyroid cancer incidents among the local children.

"Epidemiological studies alone take time [to prove a link between a disease and its cause]," he said. "And when we are able to confirm this link, it's usually too late to take countermeasures.

"If more and more people in Fukushima Prefecture develop other types of cancers [apart from thyroid], we need to think of other measures, such as providing medical checkups to investigate possible damage to genes," Kodama said.

Gov't unveils plan to expand decontamination project areas; local reactions mixed

The government has unveiled plans to sharply expand a government-funded decontamination project to areas with annual radiation emissions of 1 millisievert or more, prompting mixed reactions from local government officials and residents.

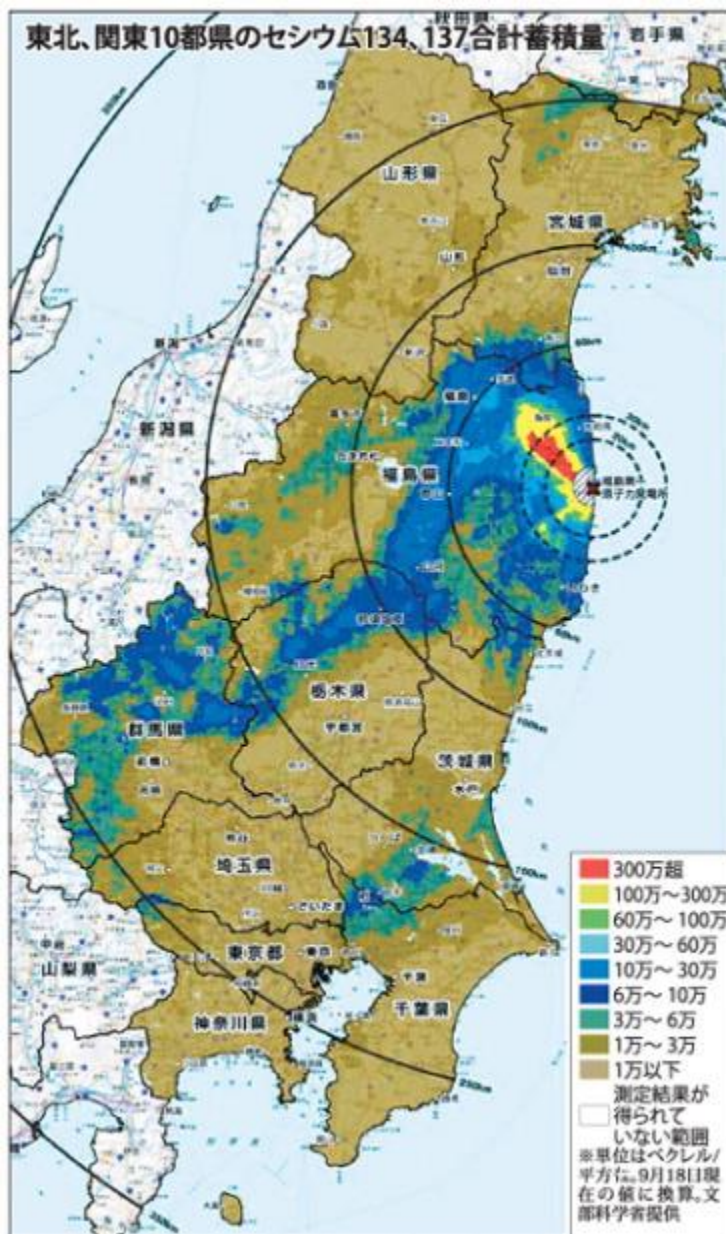

Under the plan, the Environment Ministry is to designate those areas with annual radiation exposure of 1 millisievert or more as "priority contamination inspection areas" by the end of November. In collaboration with the central government, local governments are supposed to decide on areas which need to be decontaminated and ways of decontaminating them. The central government will shoulder all the costs.

According to monitoring conducted by the Ministry of Education, Culture, Sports, Science and Technology, there are locations with annual radiation exposure of more than 1 millisievert in Tokyo, Fukushima, Miyagi, Tochigi, Gunma, Ibaraki, Chiba and Saitama prefectures. Drawing on the findings and results of other tests carried out by local municipalities, the Environment Ministry is expected to designate contaminated municipalities as "priority inspection areas".

Relatively high levels of radiation have been detected in the northwestern part of Chiba Prefecture. Seiichi Someya, head of a radiation-related taskforce at the Kashiwa Municipal Government, said, "It is impossible for the city to shoulder the decontamination costs on its own, and therefore we are thankful for the government support," adding, "We want to know the details of the project as soon as possible."

Nevertheless, some local residents are critical of the central government's response to the spread of radioactive substances from the Fukushima No. 1 nuclear plant. A 41-year-old mother of two children, who took part in a petition urging local governments to measure radiation levels and start cleanup operations, said, "It's good that the government has acknowledged the need to decontaminate areas with annual radiation of 1 millisievert or more, but it is rather late. We already knew by late April that this area was badly contaminated. Measures could have been taken earlier."

In Tokyo, meanwhile, Katsushika Ward has been measuring radiation levels at parks in seven locations every week since the end of May. Some of the parks still register 0.23 microsieverts per hour.

A government map displaying radiation levels in 10 prefectures relatively close to the Fukushima No. 1 Nuclear Power Plant. Areas in red show over 3 million becquerels of cesium per square meter, whereas those in light brown show less than 10,000. (Data as of Sept. 18. Image courtesy of the Ministry of Education, Culture, Sports, Science and Technology)

In August, the ward measured sand pits at 398 locations in such places as elementary and middle schools, parks and the like. The ward has moved to replace sand registering more than 0.25 microsieverts per hour with non-contaminated sand at 20 locations.

The "Kanamachi 2-Chome Tokiwa Park" in the ward registered 0.24 microsieverts per hour on Oct. 6. A 42-year-old office worker passing by the park said, "Because I have an elementary school child, we will feel secure if decontamination is done in accordance with the government plan."

Radioactive strontium found in Yokohama, 250 km from Fukushima plant

YOKOHAMA (Kyodo) -- Radioactive strontium exceeding normal quantities has been detected in sediment from atop an apartment building in Yokohama, some 250 kilometers from the damaged Fukushima Daiichi nuclear power plant, city officials said Wednesday.

While the discovery of 195 becquerels of strontium 90 in the rooftop sediment has fueled concerns that leaked radiation may have spread further than the government had expected, the officials said the city office is carefully examining where the material came from.

This is the first time strontium at a concentration of over 100 becquerels per kilogram has been found beyond 100 km from the Fukushima plant. The strontium 90 was detected in Yokohama, south of Tokyo, by a private agency that conducted the test upon the request of a resident.

Strontium 90, with a half-life of 29 years, has been detected at concentrations roughly between 10 to 20 becquerels at various places across Japan prior to the nuclear crisis triggered by the March 11 earthquake and tsunami.

After learning about the findings, the Yokohama city is now investigating soil samples collected from areas near the building, the officials said. Meanwhile, the science ministry said it is still uncertain whether the strontium had come from the Fukushima nuclear accident.

"Radioactive substances tend to accumulate in sediments and so we still don't know whether the substance found in this test had come from the nuclear accident," an official of the Ministry of Education, Culture, Sports, Science and Technology said.

The ministry has detected radioactive strontium at various locations in Fukushima and Miyagi prefectures within 100 km from the crippled plant in earlier investigations following the accident.

If inhaled or ingested, strontium tends to accumulate in bones just like calcium. It is believed to cause bone cancer and leukemia.

(Mainichi Japan) October 12, 2011

Yokohama tests soil for radioactive strontium

Officials in Yokohama City are testing soil for radioactive strontium following a report from a local resident in September that the substance had been detected in sediment on the roof of an apartment building.

In September, radioactive cesium more than 80 times the government-set limit of 500 becquerels per kilogram was found in sediment collected from roadside ditches in Yokohama City, which is near Tokyo.

The city later removed sediment from the area.

But the city decided to retest the sample for radioactive strontium due to the request of a local resident.

The resident said a private testing institution had detected 195 becquerels of strontium per kilogram -- more than 6 times the government safety limit -- in the rooftop sample.

The science ministry says radioactive strontium can accumulate in bones if inhaled and that it poses a cancer risk.

The ministry added that it has found strontium in the soil in Fukushima Prefecture, site of the crippled Fukushima Daiichi nuclear plant. But the agency says it has conducted few checks for the substance outside the prefecture because the amounts detected in Fukushima Prefecture were very small.

Yokohama is located about 250 kilometers from the Fukushima plant.

Radioactive substance levels in Fukushima reactor building drop below legal limits

Fukushima No. 1 nuclear plant's No. 1 reactor building, with its nearly-completed cover, is seen on Oct. 8 in this photo provided by Tokyo Electric Power Co.

Concentrations of radioactive materials inside the No. 1 reactor building at the crisis-stricken Fukushima No. 1 nuclear plant have dropped far below legal exposure limits for nuclear workers, plant operator Tokyo Electric Power Co. announced on Oct. 11.

Recent atmospheric readings taken inside the building showed concentrations of cesium 134 and 137 between one-thousandth and one-ten-thousandth becquerels per cubic centimeter -- one-tenth the legal limit for breathing air for nuclear workers. Iodine 131 was also below detectable levels.

Previous readings from September were taken above the ruined reactor building, but with the near-completion of a new cover around the structure the utility decided to take the latest measurements inside it.

Fukushima Pref. declares all newly harvested rice safe for shipment

FUKUSHIMA (Kyodo) -- Newly harvested rice from nuclear crisis-hit Fukushima Prefecture is safe for shipment after tests showed all samples cleared the government-set allowable limit for radioactive cesium, with 80 percent of the crop found to be completely free of contamination, prefectural government officials said Wednesday.

The prefecture tested a total of 1,174 samples of rice harvested in the 48 municipalities of the northeastern Japanese prefecture where the crop was grown this year and found none exceeded the 500 becquerels per kilogram limit.

However, the prefecture will buy up all the rice harvested from certain districts in Nihonmatsu where readings of radioactive cesium logged 470 becquerels, the officials said.

Meeting reporters following the announcement, Fukushima Gov. Yuhei Sato said, "I will take the initiative in marketing by stressing the safety and good taste" of rice harvested in the prefecture.

Rice was not grown in the remaining 11 municipalities in Fukushima this year as they are located within the 20-kilometer no-go zone around the radiation-leaking Fukushima Daiichi nuclear plant or other seriously contaminated areas.

The detection of radioactive cesium in excess of the 500 becquerels limit would have led to a halt of shipments from all farmers in the locality where the sample originated.

(Mainichi Japan) October 13, 2011

High levels of radiation detected in Tokyo

TOKYO (Kyodo) -- Significant levels of airborne radiation have been detected in an area of Tokyo's Setagaya Ward, exceeding readings in some evacuation zones around the crippled Fukushima Daiichi nuclear plant, prompting local officials to urge residents to stay away from the affected area.

Radiation of up to 3.35 microsieverts per hour was recorded Thursday at a height of 1 meter along a sidewalk in a residential area of Tsurumaki in Setagaya, some 230 kilometers southwest of the Fukushima plant, the officials said.

The ward is still investigating what type of radioactive material is involved, while trying to work out how to decontaminate the sidewalk, which is regularly used by pupils at a primary school. The area has been cordoned off as a precautionary measure.

The finding comes following Wednesday's media reports that a high reading of 2.71 microsieverts per hour was detected there earlier this month and that radioactive strontium exceeding normal quantities has been found in sediment atop an apartment building in Yokohama City's Kohoku Ward, some 250 kilometers away from the nuclear plant.

The reading of 3.35 microsieverts means that if a person were to stay close to the contaminated spot for an entire year, spending eight hours each day outdoors and the rest inside a wooden house, their cumulative annual radiation dose could reach about 17 millisieverts, compared with the government-set allowable limit of 20 millisieverts a year.

The local officials said the "hot spot" could have resulted from an accumulation of rainwater due to the location's sunken geological formation. **But they could not explain why radiation readings taken at a height further above the ground were higher than close to the surface where mud and dust gather.**

Research on Oct. 4 and 6 found radiation levels varied widely even along the same sidewalk, with the lowest reading at only 0.088 microsievert and 2.707 microsievert.

The officials said they have used water and other methods in attempt to decontaminate the spot, which was discovered after a resident alerted authorities, but radiation levels have shown little improvement even after the cleaning.

Michikuni Shimo, a professor in environmental radiation at the Fujita Health University, called on the public to remain calm, noting that the amount of radiation detected is not at a level regarded as dangerous.

(Mainichi Japan) October 13, 2011

High radiation in Tokyo residential area

A sidewalk in Setagaya ward, in the western part of Tokyo, has shown a radiation level of 2.707 microsieverts per hour, much higher than other areas in the same ward.

Setagaya ward made the 10-meter by 1-meter area on the roadside off limits, as elementary school

children walk by on their way to and from a nearby elementary school.

The ward tried to decontaminate the spot earlier this month by using a high-pressure washer, but it only brought down the highest radiation reading by about 0.1 microsieverts per hour.

The ward is consulting experts to figure out what to do about the highly contaminated area.

Radiation from this small patch in Setagaya would accumulate to 14.2 millisieverts per year, which is lower than the government designated evacuation level of 20 millisieverts per year.

Thursday, October 13, 2011 12:51 +0900 (JST)

Japan's food radiation limits set too high: Belarusian scientist

TOKYO (Kyodo) -- A visiting Belarusian scientist, who has offered advice to residents affected by the 1986 Chernobyl nuclear disaster, said Wednesday that he believes Japan's food radiation limits have been set too high and urged the nation to lower them to realistic levels.

Vladimir Babenko, deputy director of the Belrad Institute of Radiation Safety in the former Soviet republic, told a press conference in Tokyo that he cannot understand the thresholds designated by the Japanese government for food and beverage products, saying they are much higher than Belarusian standards.

Babenko also criticized the Japanese government for its failure to set special standards for children to better protect them from internal radiation exposure.

For example, he pointed out that the limit for radioactive cesium in 1 kilogram of drinking water is set at 200 becquerels in Japan, 20 times as high as the maximum allowable level in Belarus.

The scientist is visiting Japan to promote the Japanese translation of his book about radiation protection. He is scheduled to make a speech in Fukushima Prefecture on Friday.

(Mainichi Japan) October 13, 2011

Drill confirms safety of Fukushima nuclear plant

The operator of the Fukushima Daiichi nuclear plant says the facility could be kept safe even if its reactor-cooling system is knocked out by another huge earthquake.

Tokyo Electric Power Company conducted a drill on Wednesday based on the scenario that its pumps and tanks were damaged by a magnitude-8 quake near the plant. It was the first such drill since trouble began at the plant in March.

Reactors at the plant must receive a continuous injection of water to be kept in a state of cold shutdown, with temperatures below 100 degrees Celsius.

During the drill, about 40 workers attached a 300-meter hose to a fire truck, and pumped up seawater to inject into the reactors.

It took about an hour and 10 minutes for water to resume being injected into a mock facility after fire trucks arrived at the scene.

Tokyo Electric says water injection at the three reactors, No.1 through No. 3, could be restarted in about 3 hours.

Thursday, October 13, 2011 10:03 +0900 (JST)

Final nuclear waste disposal issue needs serious deliberation

Little progress has been made in the debate on the construction of final disposal facilities for nuclear waste, while calls urging that Japan rely less on nuclear power plants have intensified since the ongoing crisis at the tsunami-hit Fukushima No. 1 Nuclear Power Plant emerged in March.

The construction of nuclear waste final disposal facilities is an inescapable issue that Japan as a whole needs to address.

"The national government should consider buying up land around the crippled nuclear power station and build a final disposal facility for high-level radioactive waste," said a former member of the municipal assembly of a town designated as a no-entry zone, in an interview with the Mainichi. He was quoted in a series of articles on local governments tossed about by the national government's nuclear power policy, which were carried in the Mainichi Shimbun's Aug. 19-25 morning editions.

It is harsh to require only residents of Fukushima Prefecture, many of whom have been forced to evacuate from their neighborhoods and take shelter elsewhere, to make a tough decision on the issue.

I have repeatedly visited Fukushima Prefecture to write stories about the ongoing nuclear crisis, and accompanied evacuees who temporarily returned to their homes situated in a no-entry zone within a radius of 20 kilometers from the crippled power plant.

Although the designation of many areas within a 20- to 30-kilometer radius of the plant as emergency evacuation preparation zones has been lifted, there are no prospects that the no-entry zone designation will be lifted in the foreseeable future.

Some of those people who have been forced to leave their hometowns because of the harsh realities of the nuclear disaster have expressed tough determination.

Masaatsu Amano, 73, who fled his home in Futaba and is taking shelter in Koriyama, has given up hope of returning to his hometown to live, and now believes that a radioactive waste final disposal site should be built in areas around the nuclear plant. In exchange for that, he says he will demand that the central government pay him compensation that can allow him to acquire new land elsewhere to restore his livelihood.

"It is really a tough situation to face at my age, but this is the only idea I can come up with when I think about what I can do for the country. In return, I'll demand what I am entitled to from the government," he said.

A former official of the municipal government in Tomioka, which hosts the Fukushima No. 2 Nuclear Power Plant, said, "We don't want to host such a dangerous facility in our neighborhood, but we can't spread the risks throughout this small country."

Regarding final disposal, domestic legislation stipulates that nuclear waste must be solidified with glass and sealed hermetically in stainless containers and be buried 300 meters below the surface of the ground. However, experts say it will take 100,000 years before radiation in such waste declines to safe levels.

Finland and Sweden are the only countries in the world that have already decided to build nuclear waste final disposal sites, according to the Nuclear Waste Management Organization of Japan (NUMO), an affiliate of the Economy, Trade and Industry Ministry.

In Japan, NUMO began in 2002 to invite local governments to host such facilities. NUMO is supposed to conduct a three-phase safety examination, including checking records of earthquakes and volcanic eruptions and the strength of bedrock. Each local government that offers to allow NUMO to conduct only an early-stage examination is granted up to 2 billion yen as a subsidy.

In 2007, the Toyo Municipal Government in Kochi Prefecture made such an offer, but the decision stirred protests from the municipal assembly as well as local residents. The mayor was forced to call a mayoral election, and the newly elected mayor retracted the offer. Since then, NUMO's selection of a site for final disposal facilities has been deadlocked.

Currently, about 1,700 pieces of vitrified nuclear waste are stored across the country. The central government estimates that the number will increase to some 40,000 sometime around 2021. Since there are no prospects that such disposal sites will be built, a temporary nuclear waste storage facility in the Aomori Prefecture village of Rokkasho has temporarily stored much of the waste.

In this undated photo released Wednesday, April 13, 2011 by Tokyo Electric Power Co., a standing man is partially seen above an example of the truck used to move spent fuel rods in the pools. Nothing is decided yet but TEPCO told the press at its Tokyo headquarters Wednesday morning that this is one option TEPCO officials are considering to use at the tsunami-stricken Fukushima Dai-ichi nuclear power plant in Okuma town in Fukushima Prefecture, northeastern Japan. (AP Photo/Tokyo Electric Power Co.)

Local residents fear that the temporary storage facility will be made into a final disposal facility without sufficient discussion.

A former high-ranking official of the Rokkasho Municipal Government expressed mixed feelings about the situation.

"I don't think the central government can build a facility that can permanently store nuclear waste. However, if such waste is going to be stored here for 100 to 200 years, a facility that can respond to an emergency situation should be build 300 meters below the ground," the official said in an interview with the Mainichi. "It's acceptable that the facility will be made into a final disposal facility if it's necessary for the good of the country."

However, it is necessary to take into consideration Fukushima and Rokkasho residents' emotional attachment to their hometowns. Many of them are strongly opposed to the idea that it is inevitable that a final disposal facility will be built in areas where the crippled nuclear power plant is situated.

"Basically, I'm opposed to the idea. Residents firmly believe that their hometowns shouldn't be made a nuclear waste dumping site," said Toshitsuna Watanabe, mayor of the town of Okuma that has been designated as a no-entry zone. "First of all, the national government should decontaminate affected areas. It's extremely unreasonable that the government says we can't go home even before launching such efforts."

Norio Kimura, 46, a resident of Okuma currently taking shelter at a relative's home in Okayama, lost his 77-year-old father and 37-year-old wife as well as his home to the tsunami triggered by the March 11 Great East Japan Earthquake, and his 8-year-old daughter remains unaccounted for.

He has been unable to return home and cannot place his father and wife's ashes into their family tomb.

Yellow drums containing low-level radioactive waste are temporarily stored at a temporary storage site. (Photo courtesy of Taiwan's Atomic Energy Council)

"I want to return to my hometown full of memories of the three (my wife, father and daughter) even though it may take 10 or 20 years. It'd be too much if my hometown were made into a grave for nuclear waste," he said.

In the "As I see it," column, writers are supposed to conclude their stories by expressing their opinions or making assertions on the issues they write about, but I cannot do so. The issue is too serious for me to come up with a clear conclusion. I share the view that it would be out of the question to force disaster victims in Fukushima Prefecture, who have been tossed about by the government's nuclear power policy for many years, to host a nuclear waste final disposal facility.

However, it is necessary to confront the harsh reality -- now that Pandora's box has been opened, we need to deal with its consequences. The public needs to face this serious issue and consider how to handle it. I would like to do so as a member of the public. ("As I see it" by Takayuki Hakamada, Tokyo City News Department)

Editorial: Prioritization key to effective nuclear decontamination plan

The basic plan for decontamination and treatment of radioactive materials released from the crisis-stricken Fukushima No. 1 nuclear plant has been decided on. Under its provisions, the central government will designate areas with radioactive emissions of 1 millisievert per year or more "important contamination condition survey sites," and will task local governments with cleanup operations.

At first, the Environment Ministry told the Fukushima Prefectural Government and local municipalities that it planned to designate primarily areas with annual emissions of 5 millisieverts for contamination surveys. However, following strong opposition to this figure from local governments, Environment Minister Goshi Hosono -- who is also minister of state for the nuclear accident -- declared that the plan

would be revised. One millisievert per year is the upper exposure limit set by the International Commission on Radiological Protection (ICRP) for regular citizens.

Aerial radiation monitoring by the Ministry of Education, Culture, Sports, Science and Technology has revealed that contamination from the nuclear disaster has spread far beyond the borders of Fukushima Prefecture, with concentrations of radioactive materials found throughout the Kanto region. If the decontamination plan indeed seeks to tackle sites with emissions of 1 millisievert and above, there is a good chance it will be committed to decontaminating areas outside of Fukushima Prefecture as well.

While it is true that the effects of low doses of radiation on the human body are uncertain, that does not mean that cleanup operations need be conservative. However, considering decontamination costs and personnel expenses, it is important to prioritize areas for decontamination, dealing with the most dangerous sites first.

For instance, schools and the routes children take to them, residential areas and so on should be decontaminated with all haste. In the mountains, too, areas with large settlements should be given high priority. To get the entire project moving in an efficient manner, all levels of government as well as local residents must come together in serious discussion.

Meanwhile, the basic plan has also set the end of March, 2014 as the goal for cleaning up comparatively less contaminated parts of the evacuation zones around the nuclear plant. For people now living the rootless lives of nuclear crisis refugees, the revelation of a concrete timeline for them to return home is of no small significance. We strongly favor an effective policy to reduce radiation levels in those areas already below doses of 20 millisieverts per year, so that residents of these places may fulfill their hopes of going home again soon.

However, despite these bright sides to the plan, a veritable mountain of challenges remains, the largest of which is perhaps the processing of contaminated materials such as mud collected in cleanup operations. At present, the growing volumes of materials are going into temporary storage sites, but especially in Fukushima Prefecture, temporary storage space is getting increasingly scarce.

Under the decontamination plan, highly contaminated material and soil would be processed and stored in the mid-term by the prefectures where they were collected. As cleanup operations get under way in Fukushima and indeed across the Kanto region, finding such mid-term storage space has taken on serious urgency. Agreement on where to put such storage facilities is elusive as those concerned worry that the "mid-term" sites will end up being "permanent" sites, and strong resistance is to be expected from local residents of any region proposed as a disposal area host.

First of all, both the national and local governments must get a firm grasp on radiation levels in different areas, and take measures to guarantee safety. They must also make that information publicly available, and explain it to residents in easily understood terms. Knowledge and expertise must also be concentrated to develop technology to reduce the volume of contaminated soil.

(Mainichi Japan) October 12, 2011

High radiation dose readings marked in spots in Tokyo, Chiba

TOKYO (Kyodo) -- High radiation doses were reported Thursday in spots in Tokyo and neighboring Chiba Prefecture, both over 200 kilometers away from the crippled Fukushima Daiichi nuclear plant, with their readings found to exceed current dose levels in some evacuation zones around the plant.

Airborne radiation of up to 3.35 microsieverts per hour was recorded Thursday along a sidewalk in a residential area in Tokyo's Setagaya Ward in an inspection commissioned by the ward, and a citizens' group detected up to 5.82 microsieverts close to the ground at a children's theme park in Funabashi, Chiba Prefecture, local officials said.

While officials are still investigating whether the radiation resulted from the nuclear accident, the levels detected were both higher than the 2.17 microsieverts per hour measured Wednesday at the village office in Iitate, Fukushima Prefecture. The village is 45 kilometers from the plant and designated as an evacuation zone due to the relatively high radiation.

Funabashi is about 210 km from the Fukushima plant, while Setagaya is about 230 km away.

In an apparent attempt to calm public concerns over the recent spate of discoveries of contaminated spots in the Kanto area, Chief Cabinet Secretary Osamu Fujimura said Thursday morning the government will continue to step up nationwide monitoring as well as consider more necessary measures.

After learning of the findings at the H.C. Andersen Park, officials in Funabashi began checking radiation levels in the park and the affected area was made off limits by its operator. The contaminated spot is located where accumulated rain water flows into and is not normally accessed by park visitors.

In Setagaya, radiation of up to 3.35 microsieverts per hour was recorded Thursday at a height of 1 meter along the sidewalk in the Tsurumaki district, ward officials said.

The ward officials took samples of tree leaves over a home's board fence in the area concerned to investigate what type of radioactive material is involved.

They are also trying to work out how to decontaminate the sidewalk, which is regularly used by pupils at a primary school. The area has been cordoned off as a precautionary measure.

The finding comes following Wednesday's media reports that a high reading of 2.71 microsieverts per hour was detected there earlier this month and that radioactive strontium exceeding normal quantities has been found in sediment atop an apartment building in Yokohama City's Kohoku Ward, some 250 km away from the nuclear plant.

The reading of 3.35 microsieverts means that if a person were to stay close to the contaminated spot for an entire year, spending eight hours each day outdoors and the rest inside a wooden house, their cumulative annual radiation dose could reach about 17 millisieverts, compared with the government-set allowable limit of 20 millisieverts a year.

Setagaya officials said the higher radiation level could have resulted from an accumulation of rainwater due to the location's sunken geological formation. But they could not explain why radiation readings

taken at a height further above the ground were higher than close to the surface where mud and dust gather.

Research on Oct. 4 and 6 found radiation levels varied widely even along the same sidewalk, with the lowest reading at only 0.088 microsievert and the highest at 2.707 microsieverts near the fence.

More detailed checks Thursday concentrating on the section along the fence detected as little as 0.15 microsievert. At the point with the highest reading, it was 1.34 microsieverts near the ground but 3.35 microsieverts at 1 meter above surface.

The officials said they have used water and other methods in attempt to decontaminate the spot, which was discovered after a resident alerted authorities, but radiation levels have shown little improvement even after the cleaning.

Michikuni Shimo, a professor in environmental radiation at the Fujita Health University, called on the public to remain calm, noting that the amount of radiation detected is not at a level regarded as dangerous.

Setagaya hotspot unrelated to Fukushima

High levels of radioactivity observed in Tokyo's Setagaya Ward have been found to have nothing to do with the nuclear disaster in Fukushima.

Experts commissioned by the ward reported a level of 3.35 microsieverts per hour at a 1-by-10-meter area at a sidewalk near a residential fence on Thursday. A maximum of 2.707 microsieverts per hour had been detected in the location a week before.

Later on Thursday, the experts found what seemed to be the source of the radiation -- 3 or 4 old jars in a wooden box left in a storage space under the floor of a vacant house facing the sidewalk.

The jars were reportedly dirty and black, and measured about 8 centimeters long and about 6 centimeters wide.

The radiation level of the bottles reportedly exceeded 30 microsieverts per hour -- higher than the maximum that could be measured with the experts' devices.

After obtaining permission from the house's owner, the experts measured radiation levels on the premises.

The ward says it will take steps to eliminate the radiation while consulting the science ministry and other authorities.

Radium may be cause of radiation in Setagaya

The Japanese education ministry says the high level of radiation detected in a residential area in Tokyo is likely to have come from radium 226, and has nothing to do with the nuclear disaster in Fukushima.

High levels of radiation were found at a patch of sidewalk in Setagaya Ward in Tokyo about a week ago.

Dozens of glass jars were found in a wooden box under the floor of a house facing the sidewalk by experts commissioned by the ward.

The ministry sent the experts to investigate, and a high level of radiation, 600 microsieverts per hour, was detected on the surface of the jars.

The jars contained a powder.

The experts put the glass jars in a lead box which blocks radiation and moved it away from the residential fence.

The level of radiation at the fence then dropped from around 3 microsieverts per hour to 0.1 to 0.3 microsieverts.

Analysis of the energy of the radiation revealed that the radioactive material is highly likely to be radium 226 which is used for cancer treatment and fluorescent paint.

The education ministry will investigate why the substance was there without permission.

The radioactive substance will be removed from the house on Friday and be stored in a secure place.

Gov't white paper on energy not to call for promotion of nuclear energy

TOKYO (Kyodo) -- A government white paper on energy, which is expected to be approved by the Cabinet soon, will not call for the promotion of nuclear energy in line with Prime Minister Yoshihiko Noda's policy of reducing the nation's reliance on nuclear power following the Fukushima nuclear disaster, government sources said Thursday.

The paper, however, stipulates the government's intention to resume operations of idled nuclear plants after regular checkups to secure power generation capacity for the time being, the sources said.

The latest energy white paper lacks descriptions of the advantages and significance of nuclear energy that were seen in the past annual documents. The government delayed the release of the fiscal 2010 white paper in the aftermath of the March 11 disaster.

Sentences on the government's policy of promoting nuclear power "as a key power source" and claims that "safety measures against quakes and tsunami have been fully implemented" at nuclear plants, were not included in the latest white paper, according to the sources.

The document says the Fukushima disaster triggered by the March earthquake and tsunami "underlined challenges to secure safety" at nuclear power plants, but emphasizes the policy of restarting idled plants on condition that their safety will be more closely scrutinized and local consent for the restart will be obtained.

(Mainichi Japan) October 14, 2011

Extra school texts on radiation fail to detail nuke accident

TOKYO (Kyodo) -- The education ministry on Friday unveiled supplementary school texts on radiation compiled in the wake of the nuclear crisis at the Fukushima Daiichi power plant, but critics blasted them for failing to adequately describe the disaster or associated health risks.

The three texts are for elementary schools and junior and senior high schools respectively and describe the basic nature of radiation and day-to-day radiation exposure.

But critics say they fail to refer closely to the disaster at the Fukushima complex and the health risks caused.

For example, the materials for elementary school children touch on health risks only by noting, "It has not been clearly proved that exposure to radiation of less than 100 millisieverts at one time causes cancer and other diseases by itself, but it is important to minimize the exposure as much as possible."

Masako Sawai, researcher at the Citizens' Nuclear Information Center, said the supplementary materials "should have clearly noted how the (radioactive) contamination has spread following the nuclear disaster and how it will affect our future."

"As children are forced to face radioactive materials into the future, the government has a responsibility to explain the post-disaster situation and risks caused by radiation," Sawai said.

It cost around 36 million yen to compile the supplementary materials, and the Ministry of Education, Culture, Sports, Science and Technology will distribute the 80,000 copies to schools and education boards across the country later this month.

They will also be made public on the ministry's website.

(Mainichi Japan) October 14, 2011

Education ministry compiles booklets on radiation

The education ministry has published booklets designed to provide students with basic knowledge on radiation, in response to increasing calls for such materials in the wake of the Fukushima nuclear plant accident.

The ministry released the 20-page booklets on Friday. There are three versions, targeting students in elementary, junior high, and high school.

The books focus mainly on basic information on radiation, its effects on human health, and ways to protect oneself from radiation exposure.

The Fukushima accident is only referred to in the preface. The text does not mention the cause or any other details of the accident.

The book for elementary school pupils explains the unit "sievert", which measures the extent of damage the human body receives from radiation exposure.

It also explains that the average radiation exposure from Japan's natural environment is about 1.5 millisievert a year.

The booklet for junior high schools explains the difference between internal and external exposure, using charts to show how radiation exposure affects human health.

After the accident in March, parents urged schools to teach children basic facts on radiation. In responding to those requests, the ministry compiled the booklets in cooperation with experts on radioactivity and radiation exposure.

Radioactive cesium found in mushrooms in Kanto

Yokohama City has stopped using dried shiitake mushrooms in school lunches after detecting 350 becquerels per kilogram of radioactive cesium in its stocks.

The city said on Thursday that it discovered the contamination during its screening of ingredients for school lunches.

Also on Thursday, 830 becquerels per kilogram of radioactive cesium, exceeding the government's limit of 500 becquerels, was detected in shiitake mushrooms grown outdoors on logs in a city in Ibaraki Prefecture.

The city is about 170 kilometers from the Fukushima Daiichi nuclear plant.

Earlier this week, shiitake mushrooms containing radioactive cesium above the official limit were found in 2 cities in Chiba Prefecture.

Restrictions have been imposed on shipments of mushrooms grown by the same method in these cities.

Yokohama says the radioactive cesium detected in the city was below the government's limit, but it has decided not to use dried shiitake in children's lunches for some time.

Editorial: Safety assurances for consumers and producers still a major task

The Fukushima Prefectural Government announced Oct. 13 that the prefecture's newly harvested rice was safe, after tests found the rice to have lower levels of radioactive cesium than the provisional safety limit set by the government (500 becquerels per kilogram). While this officially gives Fukushima rice farmers the go-ahead to put their rice on the market, the farmers are concerned that their rice may not sell at all, given the possibility that consumers may avoid Fukushima-made rice based on fears of radiation contamination.

What both consumers and producers of rice want is the assurance that the rice that makes it onto the market is safe. The central and municipal governments must establish a more scrupulous testing arrangement, and hurry in their efforts to decontaminate radiation-tainted soil.

A pre-harvest test of rice made in one section of the Obama district of Nihonmatsu, Fukushima, detected radioactive cesium exceeding levels permitted by the government. As a result, seven times the number of areas marked for pre-harvest testing were tested, and testing of harvest rice was conducted as well.

To begin with, the Ministry of Agriculture, Forestry and Fisheries (MAFF) had not expected radiation levels to exceed maximum permissible amounts in the pre-harvest testing phase. Expecting rice plants to absorb cesium from the soil at a maximum 10 percent, the ministry had restricted rice planting in areas where the soil was contaminated at 5,000 becquerels per kilogram of soil.

The MAFF's predictions were ultimately shown to be mistaken, but the reasons for it are still unknown. To prevent the same thing from happening again with other agricultural products or next year's rice, the ministry must act swiftly to pinpoint the reasons such levels of cesium accumulated.

In order to foster a sense of security among consumers, it is important to increase the number of locations that are checked, thereby preventing samples from slipping past detection. We face great challenges, such as acquiring more expensive testing equipment, and we hope the national and municipal governments will cooperate to overcome such challenges.

Regardless, as long as the soil is tainted with radioactive materials, fears over agricultural products will not be completely assuaged. Decontamination of farm land is a must, and is something that the government must deal with immediately.

Meanwhile, the price of newly harvested rice is on the rise. The National Federation of Agricultural Co-operative Associations (known as Zeno or JA) is selling to wholesalers at prices 10 to 20 percent higher than the same period the previous year, and between wholesalers themselves, rice is being sold at prices about 1 percent higher than that. The reason for this is wholesalers' sense of urgency in securing rice, in the case that the current situation surrounding radiation could result in a low supply. The price of rice found in stores has also begun to rise by about 10 percent.

According to MAFF, the national average of the rice-crop index for rice produced this year is comparable to past years, and the overall harvest is expected to exceed demand. To prevent anxiety from causing alarm, consumers also must stay calm and avoid behavior that was seen immediately after the March 11 disasters, such as buying up products.

IAEA team reports to nuclear crisis minister

Experts from the International Atomic Energy Agency have advised the Japanese government on how to effectively remove radioactive substances resulting from the accident at the Fukushima Daiichi

nuclear plant.

On Friday, the team of experts in radiation-related fields submitted a 12-point report to Japan's Environment Minister, Goshi Hosono.

In the report, the IAEA team recommends preferentially decontaminating areas where high levels of radiation have been detected.

Since their arrival a week ago, the 12 experts have inspected decontamination work in Fukushima Prefecture being carried out by both central and local government.

The team leader, Juan Carlos Lentijo, told Hosono that as Japan is facing a very serious challenge, he hopes the report will help enhance its decontamination measures.

After the meeting Hosono said that, as a whole, Japan's decontamination efforts are going in the right direction. He added that further clean-up operations will take the report's advice into account.

Friday, October 14, 2011 21:10 +0900 (JST)

Hot spot in Funabashi City

Funabashi City, in Chiba Prefecture, east of Tokyo, says relatively high levels of radiation have been detected at a local park.

The city said a citizens' group reported on Wednesday that the radiation levels in the park were measured at up to 5.82 microsieverts per hour.

The city conducted its own measurements at the site on Thursday, and got maximum readings of 1.55 microsieverts per hour, one centimeter above the ground.

The city removed the surface soil at the site, and plans to conduct more detailed inspections.

Separately, Chief Cabinet Secretary Osamu Fujimura said on Friday that the central government is responsible for decontamination work.

He added that the environment ministry, the science ministry, and the Cabinet Office will discuss the issue later on Friday.

Friday, October 14, 2011 13:11 +0900 (JST)

Radiation-tainted sludge, ash to be buried in Tokyo Bay landfill

The Tokyo Metropolitan Government has decided to bury some 3,000 tons of sludge and incineration ash contaminated with radioactive materials in a Tokyo Bay landfill area as part of a breakwater construction project, it has been learned.

Tokyo's Ota and Koto wards, which are adjacent the area for the proposed breakwater have reportedly agreed on the measure.

Ota Mayor Tadayoshi Matsubara explained the move at a ward assembly meeting on Oct. 12, saying it was "unavoidable." Later he asked the Tokyo Metropolitan Government to ensure that radioactivity of materials being brought in to a solidification facility in the ward be kept below 8,000 becquerels per kilogram, that vehicles transporting the incineration ash be carefully checked for radiation, and that water used to wash vehicles be thoroughly managed.

In Koto Ward, when the chief of the Tokyo Metropolitan Government's Regional Sewerage Office approached Mayor Takaaki Yamazaki in September about the idea, he had indicated that he would accept the proposal.

The ash contaminated with radioactive materials was produced by water treatment facilities in Tokyo's Tama district. Altogether there are seven water treatment facilities in the Tama district that are directly managed by the Tokyo Metropolitan Government. The Tokyo cities of Hachioji, Tachikawa, Machida and Mitaka also have their own water treatment facilities.

The facilities had stored sludge and incineration ash found to be contaminated with radioactive materials, but it was becoming difficult to secure facilities to process the waste.

TEPCO completes cover around Fukushima plant's No. 1 reactor; 3 and 4 next

The completed cover around the Fukushima No. 1 nuclear plant's No. 1 reactor building is seen on Oct. 14 in this photo provided by Tokyo Electric Power Co.

A cover enclosing the ruined No. 1 reactor building at the Fukushima No. 1 nuclear plant has been completed, plant operator Tokyo Electric Power Co. announced on Oct. 14.

Construction of the cover -- composed of 62 polyester fibre sections -- began in August to reduce the amount of radioactive materials escaping into the outside environment. With the cover now finished, TEPCO will install air scrubbers inside the reactor building to clear out airborne radioactive substances.

Once the scrubbers are in place, they are expected to process all the air in the enclosure -- a volume of about 40,000 cubic meters -- every hour, reducing airborne radioactive materials by 90 percent.

The new cover will last for two years. TEPCO is also considering replacing the cover with a stronger one should the firm decide to remove the fuel from the reactor. TEPCO plans to build similar covers over the No. 3 and 4 reactor buildings, which were also destroyed by hydrogen explosions in March.

TEPCO also released video taken by a robot on the No. 1 reactor building's first floor. The video showed there was no longer steam rising from below ground in the building, but the robot detected extremely high radiation emissions of 4,700 millisieverts per hour.

Radiation booklet plan gets mixed reception

The Yomiuri Shimbun

The government's plan to distribute new supplementary material on energy to schools, focusing on the basics of radiation, is receiving mixed reactions.

The Education, Culture, Sports, Science and Technology Ministry is replacing earlier supplementary booklets on the same subject for primary, middle and high school students. It instructed schools not to use the previous booklets following the nuclear accident at the Fukushima No. 1 nuclear power plant, after learning they included improper descriptions about nuclear power plants.

"As the [new] supplementary material was created by the education ministry, we can use it in classes without worries," said Shiro Hayashi, 63, principal of Takinogawa Primary School in Kita Ward, Tokyo.

In May, the school's sixth graders listened to a lecture about radiation given by an official dispatched from the Japan Science Foundation in Tokyo.

After learning from reports that victims of the nuclear disaster forced to take shelter experienced discrimination, the school decided to hold the lecture to give students more precise knowledge about radiation.

Before producing the new booklets, the government had not provided materials about radiation for primary school students, considering the subject inappropriate for them. After the accident at the Fukushima No. 1 nuclear power plant, the school tried to find study material about radiation on the Internet.

"It was hard to find material that explains radiation understandably from a neutral standpoint," Hayashi said.

As part of new teaching guidelines to be fully implemented in middle schools starting in the 2012 academic year, the science guideline--which refers to radiation studies for the first time in 30 years--was implemented in the 2009 academic year.

Masaki Kobayashi, 51, a teacher of Kaishin Dai-Ichi Primary School in Nerima Ward, Tokyo, plans to teach about radiation in his science class as early as next year.

"As the supplementary material has too much content," he said, "I'm worried how to teach students about the risks of radiation or how to protect themselves [from radiation] in the limited class time, without leaving them feeling uncertain. Teachers also need to study [about radiation]."

Hisao Oshimizu, 60, principal of Ono Primary School in Okumamachi, Fukushima Prefecture, said: "When children go back to their hometown, knowledge about radiation will become necessary. We'd like to teach about it gradually." The students of the school evacuated as a group to Aizu-Wakamatsu in Fukushima Prefecture after the nuclear accident.

Watari Middle School, in the Watari district of Fukushima, measures radiation at the school almost every week. The Watari district has shown radiation levels that are relatively higher than elsewhere in the city.

While the school informs the students' parents of the radiation levels, it refrains from explaining the effects of radiation to students as it believes the word "radiation" would cause stress for some children, the school said.

Yoshinori Saito, 59, principal of the school, criticized the government's position on teaching about radiation, saying, "The information [in the new supplementary material] should have been distributed to schools before the [Fukushima] accident happened."

Meanwhile, Hosei University Prof. Takeo Samaki said: "I don't think schoolteachers will be able to teach about the effects of radiation on human bodies, which is the most important point, because the material does not clearly describe them. "Opinions are divided even among scholars over the bodily effects of a one-time exposure to below 100 millisieverts of radiation. To enable children to make objective judgments, essays expressing various opinions should have been included in the supplementary material," he said.

(Oct. 16, 2011)

Doubts over how to teach radiation

Fumihiko Ito / Yomiuri Shimbun Staff Writer

New supplementary materials about the basics of radiation will be distributed to primary, middle and high schools, but how exactly they should be used remains unclear.

The Education, Culture, Sports, Science and Technology Ministry on Friday unveiled new reading materials on atomic energy amid the crisis at Tokyo Electric Power Co.'s Fukushima No. 1 nuclear power plant.

The booklets had been completely revised, as previous versions were criticized after the outbreak of the crisis for including inappropriate descriptions of nuclear power plants and atomic energy.

However, the latest material contains little information regarding the nuclear crisis and concrete measures to deal with it.

Middle schools have not taught about radiation for 30 years, and how schools use the supplementary materials will be a key issue in teaching about radiation at schools.

The beginning of the booklet for primary school students says, "After the nuclear accidents occurred, materials that emit radiation leaked from the nuclear power plant."

But it does not mention the nuclear crisis in the main text.

According to the ministry, some of the 13 authors of the booklets said they should describe the crisis, including conditions in Fukushima Prefecture. However, most insisted it was more important to first provide information to students about radiation, so they would understand how disaster-hit areas were contaminated.

The booklets, for example, write that radiation is constantly present in the natural environment and explain about units such as sieverts and becquerels. They also explain that radiation is used in various fields such as medicine, agriculture and industry, using many pictures.

Regarding human exposure to radiation, the booklets describe external exposure resulting from cosmic rays or X-rays, and internal exposure from ingestion of contaminated food or inhaling radiation.

They also write that Japanese receive an average of about 1.5 millisieverts of radiation annually from natural sources, and the average individual in the world receives about 2.4 millisieverts annually.

The new material instructs students to keep away from radioactive materials and shorten the time they are exposed to radiation, to protect themselves from radiation.

To prevent internal exposure, the books instruct students to cover their mouths by using masks or other means, and not to eat food the intake of which has been restricted.

Regarding the connection between radiation doses and health, one booklet says, "There is no clear evidence that people develop cancer from radiation doses below 100 millisieverts.

"It is not necessary to worry about radiation doses if the radiation comes from the natural environment or common practices such as an X-ray, but it is important to avoid receiving radiation as much as possible."

The booklet for primary students writes, "Radiation does not spread from person to person."

Regarding the damage suffered by Fukushima residents as a result of radiation fears, and students from the prefecture being bullied, a teaching guideline for primary school teachers says, "Bullying and discrimination [due to radiation] should not occur."

Such instruction is not mentioned in the booklets for students, however.

An essay in the booklet for high school students describes the "risk and benefit" theory that is used in medicine. "When people use something for their benefit, they cannot avoid a certain amount of risk," the column states.

This is implying that nuclear power plants bring benefits such as power supply, and risks such as radiation.

"[The essay] seems to be trying to justify the measures taken by the government regarding the nuclear crisis," said Hosei University Prof. Takeo Samaki, who specializes in science education.

(Oct. 16, 2011)

NISA secretly calculated Fukushima meltdown risks / Agency considered worst-case scenario of 'China syndrome'

The Yomiuri Shimbun

Erosion of bottom of containment vessel

The Nuclear and Industrial Safety Agency secretly calculated the possibility of a worst-case meltdown at Tokyo Electric Power Co.'s Fukushima No. 1 power plant, it has been learned.

The agency was working on the calculations just as TEPCO was saying the nuclear fuel in three reactors at the plant was "slightly damaged."

The trial calculations were made under the premise that the nuclear fuel at the plant's No. 1 to No. 3 reactors would melt down entirely, developing into a so-called China syndrome, the worst-possible scenario.

Coined in the United States, China syndrome refers to an imagined worst-case meltdown of nuclear fuel that burns through the bottom of a containment vessel and eventually through the Earth's crust until finally reaching China.

The trial calculations were carried out first on March 25, two weeks after the March 11 accident, followed by further calculations on April 6, 7 and 13.

The fact that the calculations were carried out secretly was revealed Friday by the **Japan Nuclear Energy Safety Organization (JNES)**, an independent administrative institution, which had been commissioned by the agency to undertake the trial estimations.

The calculations indicated that if cooling water could not be injected, erosion could continue for more than 10 days, badly damaging the three-meter thick concrete walls of the Nos. 2 and 3 reactors' containment vessels, the JNES said.

The erosion of the bottom of the No. 1 reactor's containment vessel bottom would possibly stop after the vessel wall was eroded to a depth of 1.8 meters in eight days, according to the calculations.

When the JNES calculations were being conducted, both the agency--the nuclear safety watchdog of the Economy, Trade and Industry Ministry--and TEPCO publicly said the nuclear fuel in the reactors was "slightly damaged."

In announcing the calculation results Friday, the JNES said it had roughly gauged the extent to which the floor of the containment vessel bottoms, called "pedestals," would be eroded should all the nuclear fuel drop through the pressure vessel of the three reactors.

The calculations were carried out based on different scenarios. In one of them, all reactor cores dropped out at the same time, and in another, melted fuel jetted out of the vessels, the JNES said.

It said the calculation results were conveyed to the agency, but it is unknown whether the information was shared with the Cabinet Office or other government organizations.

Regarding the announcement of the calculations a half year after the outbreak of the crisis, the JNES said although the calculations were exclusively for the sake of studies within the agency and TEPCO, it decided to make them public as the initial phase of coping with the crisis has finished.

On April 18 the agency acknowledged the reactors' fuel had begun to melt down, but TEPCO failed to acknowledge the possibility of a meltdown until April 20.

(Oct. 16, 2011)

Cold shutdown will be achieved within this year

The Japanese government and Tokyo Electric Power Company say that a cold shutdown of the crippled Fukushima Daiichi nuclear power plant will be achieved by the end of this year.

It will be included in a revised timetable for containing the nuclear crisis that will be issued on Monday.

They say the temperatures around the No.1, No.2, and No.3 reactors are less than 100 degrees Celsius and the amount of radioactive material being emitted has dropped to about half the level of a month ago.

The latest survey showed estimated radiation levels of about 100 million becquerels per hour.

Also a giant polyester covering for the No.1 reactor building will be completed by the end of October.[\[isn't it ready ???\]](#)

The government and TEPCO say measures to achieve the state of a stable cold shutdown are progressing steadily.

On Monday TEPCO will submit to the government nuclear safety measures that will apply to its work

to maintain a state of cold shutdown over the coming 3 years.

Goshi Hosono, the minister in charge of the nuclear disaster said in September that they would try to achieve cold shutdown by the end of this year. It had originally been planned for January next year.

Photos released by TEPCO show huge piles of used radioactive gear

Huge piles of plastic bags containing used radioactive gear and other contaminated waste are seen at the J-Village facility. (Photo courtesy of TEPCO)

An infrared view from above the No. 1 reactor building at the Fukushima No. 1 Nuclear Power Plant is seen in this photo taken Oct. 15. (Photo courtesy of TEPCO)

Photos released by the Tokyo Electric Power Co. (TEPCO) show huge piles of plastic bags containing used radioactive gear and other radioactively contaminated waste at a facility near the Fukushima No. 1 Nuclear Power Plant.

The photos show a vast number of bags piled about five meters tall. According to TEPCO, there are currently around 4,000 cubic meters of the waste piled up.

The photos are two of 32 released by TEPCO on Oct. 15 and were taken at J-Village, a sports facility serving as a base of operations for workers trying to control the nuclear plant. Other released photos show medical rooms and shops set up in the facility.

Photos taken with an infrared camera over the No. 1 and 3 reactor buildings were also released. They were taken with a camera attached to a crane, as radiation levels in the buildings are too high for people to enter them.

According to TEPCO, the hottest spot photographed of the No. 1 reactor building was around 35 degrees Celsius, and the hottest spot for the No. 3 reactor building was around 40 degrees Celsius. They believe these hot areas were due to steam escaping from small openings in the concrete lids of the reactors' containment vessels. The average temperature of the reactor buildings' exteriors was around 20 degrees Celsius.

TEPCO said that, "The steam vapor we saw before is now gone. The reactors are **probably** getting cooler."

Facing the reality of radioactive decontamination

Shinzo Kimura, an associate professor in radiation hygiene at Dokkyo Medical University, has stood at the forefront of radiation decontamination efforts in Japan, listening to residents living in areas of Fukushima that are heavily contaminated with radiation.

Kimura originally worked as a researcher at a corporation under the jurisdiction of the Ministry of Health, Labor and Welfare, but the organization restrained him from conducting a survey in Fukushima right after the outbreak of the Fukushima No. 1 Nuclear Power Plant catastrophe, so he immediately quit. He entered the affected area on March 15, just four days after the March 11 quake and tsunami, and created a radiation contamination map based on his surveys. He also toured various areas offering support to residents.

Kimura's efforts were featured three times in specials on NHK's education channel, eliciting a great response from the public, so his efforts are known in Japan to a certain degree. As an experienced researcher, Kimura understands how big the job of decontamination is.

"Decontamination is extremely difficult," he says. "Without special equipment, even if someone worked frantically for two days to decontaminate his or her home, the amount of radioactive materials would only be reduced by about half.

"To decontaminate homes in hot areas (areas with localized high radiation levels), a space within a 100-meter radius of each home must also be decontaminated; otherwise radiation will not fall back down to 0.1 microsievert per hour (the level occurring naturally in the environment). In practical terms I think this is near impossible."

In his policy speech after taking office, Prime Minister Yoshihiko Noda stated he would put a full effort into addressing the nuclear disaster, while the minister in charge of handling the nuclear disaster

stated that Japan would carry out measures without taking into account the economics involved. But it is Kimura's comments that reveal the reality of the situation.

In order to understand the reality, radiation levels must first be measured. When I went to the city of Fukushima the other day, my radiation dosage meter showed a level of 0 microsieverts at the time of my departure from Tokyo. After staying overnight in Fukushima and then returning to the capital, the reading was 2 microsieverts. Over the next three days in Tokyo, the total dosage rose to 6 microsieverts.

I approached an expert about this, commenting that the level in Tokyo was also high. I received the following response:

"The level of naturally occurring radiation is 0.05 microsieverts per hour, so that's nothing out of the ordinary. Two microsieverts for 24 hours spent in Fukushima is normal."

The device I was carrying showed the accumulated external radiation dosage. This type of device functions differently from measurement equipment that gauges the specific amount of radiation in the atmosphere at any given time. Hitachi-Aloka Medical, one of Japan's biggest producers of such devices, says that one popular dosimeter is priced at about 30,000 yen. Radiation measurement devices cost in the range of 245,000 yen. Both types are reportedly in short supply with **customers having to wait several months for radiation measurement devices.**

"Before the quake and tsunami disaster, we were only putting out a few hundred a year, but now we're selling 400 to 500 a month," a company representative says. The company has reportedly received inquiries from all over Japan, but predominantly from people in the Kanto region. This is understandable. Recently in the Tokyo metropolitan area there has been a lot of talk about spots with high levels of radiation and their decontamination.

Kimura has the following to say about the issue:

"There is no need to fret at every little thing. We should be cautious in an appropriate manner."

This summer pine wood contaminated with cesium from Rikuzentakata was barred from being used in a ritual in Kyoto. Kimura says that this was a typical example of unreasonable fear.

After the outbreak of the nuclear crisis triggered by the March 11 quake and tsunami, a thick radioactive cloud hung over the Japanese archipelago. **But even before that, Japan was already contaminated with radiation from past nuclear tests and the Chernobyl disaster.** Compared with this radiation, the level in the pine wood was several hundred thousandths of the amount.

Workers scrub the parking lot of the Minamisoma city hall in Fukushima Prefecture during radiation decontamination work on Sept. 30. (Mainichi)

Nevertheless, the fundamental concept that excessive exposure to radiation harms people's genes and could threaten preservation of the species remains unchanged. Restraining internal exposure to radiation from contaminated food remains an issue. What safeguards are appropriate and what is the correct method of decontamination?

Seeking such answers, Kimura is now in the Narodychi district of the Zhytomyr Oblast province of Ukraine, conducting his 15th survey on contamination from the Chernobyl disaster.

Regardless of whether people support or are against nuclear power, they must live with radioactive materials that have already been scattered.

We must understand that decontamination is a difficult task that cannot be solved by merely making declarations of determination or fixing budgets. (By Takao Yamada, Expert Senior Writer)

Gov't and TEPCO to aim for 'cold shutdown' of Fukushima reactors by year-end

The government and the Tokyo Electric Power Co. (TEPCO) are expected to announce that they will aim for a stable condition called "cold shutdown" of the nuclear reactors at the crippled Fukushima No. 1 Nuclear Power Plant by the end of this year, slightly earlier than the originally planned deadline of mid-January.

The government will hold a meeting of its nuclear disaster taskforce as early as December to decide on whether they can call the "step 2" phase of the roadmap to bring the nuclear power plant under control finished. This "step 2" phase aims for "having the release of radioactive material under control and a sharp curb in radiation levels." The target period for achieving step 2 was set for "between mid-October and mid-January next year."

One condition for achieving a cold shutdown was having the temperature at the bottom of each reactor pressure vessel of the No. 1 to 3 nuclear reactors at the Fukushima plant under 100 degrees Celsius

from the beginning of this month -- a condition currently being met. Furthermore, according to TEPCO, the amount of radioactive substances being released from the nuclear reactor buildings from Sept. 1 to Sept. 15 was about 200 million becquerels per hour, about one four-millionth of what was measured immediately after the outbreak of the nuclear crisis, and the amount of radiation on the outer premises of the nuclear plant's grounds is estimated to be at most 0.4 millisieverts per year, below the legal limit.

For these reasons, senior officials of the Ministry of Economy, Trade and Industry judged that "it is fully possible to achieve (a cold shutdown) ahead of schedule."

With respect to the possibility of achieving a cold shutdown by the end of this year, nuclear disaster minister Goshi Hosono said at an annual conference of the International Atomic Energy Agency (IAEA) in Vienna on Sept. 19, "We will do our best to achieve it by the end of this year." But when the government and TEPCO revised the nuclear disaster response roadmap on Sept. 20, they avoided making any promises, with Cabinet Office Parliamentary Secretary Yasuhiro Sonoda saying a cold shut down this year was "a nonbinding target because there are risks of torrential rains and aftershocks."

The report said the utility prompted employees and residents backing its so-called "pluthermal" project to express opinions in support at symposiums and other events organized by the central and Hokkaido governments over the contentious project.

Plutonium-thermal power generation uses plutonium-uranium mixed oxide fuel, which contains plutonium extracted from spent fuel, in existing reactors and is an important pillar of Japan's nuclear fuel recycling program.

(Mainichi Japan) October 18, 2011

TEPCO reports measures to ensure cold shutdown

Tokyo Electric Power Company has submitted a report to the government on the steps it will take to ensure a state of cold shutdown at its crippled Fukushima Daiichi nuclear power plant.

Japan's Nuclear and Industrial Safety Agency had asked TEPCO to outline its nuclear safety measures over the coming 3 years.

The utility aims to bring temperatures at all its reactors to below 100 degrees Celsius over the next few months.

It said on Monday that additional pumps to inject water into the nuclear reactors would be set up inside turbine buildings, and existing hoses replaced with stronger ones.

The utility maintains that even if an earthquake and tsunami were to halt the water-injection systems, they could be resumed within 12 hours to prevent major accidents.

Monday, October 17, 2011 20:02 +0900 (JST)

Hokkaido Electric freezes plutonium-thermal generation project

SAPPORO (Kyodo) -- Hokkaido Electric Power Co. will freeze a plutonium-thermal power generation project at the No. 3 reactor of its Tomari nuclear plant due to a scandal involving the misrepresentation of local opinion regarding the project, its president Yoshitaka Sato said Monday.

Sato also told a press conference at the company's head office in Sapporo that the utility has decided to impose 30 percent salary cuts on him, Chairman Tatsuo Kondo and two executive vice presidents, and 20 percent salary cuts on two managing directors, all for three months.

Sato said he would accept the findings of a report filed by a third-party panel set up by the company to look into the scandal and the utility has submitted the report to the Ministry of Economy, Trade and Industry.

The report said the utility prompted employees and residents backing its so-called "pluthermal" project to express opinions in support at symposiums and other events organized by the central and Hokkaido governments over the contentious project.

Plutonium-thermal power generation uses plutonium-uranium mixed oxide fuel, which contains plutonium extracted from spent fuel, in existing reactors and is an important pillar of Japan's nuclear fuel recycling program.

Fukushima nuclear evacuees to undergo mental health checks

FUKUSHIMA (Kyodo) -- The Fukushima prefectural government will conduct mental health checks from next month on about 200,000 residents who had to evacuate in the wake of the Fukushima nuclear crisis, its health committee said Monday.

It will also start conducting checkups on about 20,000 pregnant women within this year, the panel of experts said.

After the 1986 nuclear disaster in Chernobyl, the number of people suffering from mental illness is believed to have increased due to radiation fears and changes in their living circumstances.

Residents subject to Fukushima's survey will be divided into four groups -- children up to age 6, elementary school students, junior high school students, and senior high school age and older people.

As for children up to junior high school age, their parents will be required to check whether any changes in their children's behavior have been observed, such as whether they tend to be scared or get angry suddenly.

Older people will be required to answer questions regarding stress and posttraumatic stress disorder, as well as whether they have experienced any changes in their lifestyles including sleep and diet after the nuclear disaster.

The prefectural government will offer telephone consultations or introduce medical institutions to those who may need treatment, the committee said.

All pregnant women who have been given maternity health record books in the prefecture from August 2010 to July 2011, including those who have evacuated outside Fukushima after the accident, are subject to the checkups, it said.

Fukushima City begins decontamination work

Fukushima City has launched a massive campaign to clean up radioactive materials, with the ultimate goal of decontaminating all homes and public facilities.

The city is located about 60 kilometers from the disaster-stricken Daiichi nuclear power plant.

Decontamination work began on Tuesday morning in the Onami district, where radiation levels are relatively high.

Prime Minister Yoshihiko Noda was on hand for about 20 minutes to inspect the work in Onami.

A team of **professional workers** [who are they ?] used water jet cleaners to clean roofs and ditches. They also cut away vegetation in gardens and removed a layer of top soil.

Fukushima City's ultimate goal is to decontaminate 110,000 households, public facilities, and roads near schools by the end of fiscal 2012.

The city plans to ask residents and volunteers to help clean up areas where radiation levels are not too high.

Securing the necessary manpower and space to store radioactive waste are among the key challenges.

Tuesday, October 18, 2011 12:16 +0900 (JST)

TEPCO identifies risks that could cause meltdown

The operator of the damaged Fukushima Daiichi nuclear plant says the water-injection system, which has external pipes, is the area that's most likely to cause possible problems in future.

The external system was built as an emergency response to the meltdown that occurred after the March 11 disaster.

Tokyo Electric Power Company has calculated the risks to the water-injection system which could lead

to the cooling water supply being stopped, resulting in another meltdown.

TEPCO analyzed 7 scenarios where the state of a reactor in cold shutdown is undermined due the water supply stopping for more than 18 hours.

Cold shutdown means the temperature of the reactors is below 100 degrees Celsius, and stable.

The cases include damage to the water-injection system and external power outages.

TEPCO found that the highest risk involves a case where the water-injection system is swept away by a massive tsunami and the water supply to the reactors stops.

The second most dangerous scenario is where the water-injection system is destroyed and the resumption of the system fails.

The company found that outside pumps and pipes that were built as an emergency solution after the nuclear accident are 10-times more likely to sustain damage than conventional ones inside the building.

TEPCO plans to reinforce the emergency facilities to maintain the water supply in case of a huge tsunami.

Decontamination work underway in Fukushima, but many choosing not to return

A worker, front, uses heavy machinery to remove vegetation from Yoshiharu Suda's yard, while another man at the back works to decontaminate the roof of his house in the Onami district in the city of Fukushima, on Oct. 18. (Mainichi)

FUKUSHIMA -- District-wide radiation decontamination work got underway on Oct. 18 in the Onami district of Fukushima city, but regardless, many families are choosing to have their children live elsewhere to avoid exposure to radiation.

One such family is that of Yoshiharu Suda, 61, whose house in the Onami district was the first to have decontamination work carried out on it. After the disaster at the Fukushima No. 1 Nuclear Power Plant, his only son, Takahiro, who is 18 and soon to leave the house for university, said he will not live in Fukushima Prefecture.

The Onami district has high radiation levels, thought to have come from the heavily damaged nuclear plant. Located in the eastern part of Fukushima city, Onami is a hilly area around 60 kilometers removed from the nuclear plant, a farming landscape where the people have lived self-sufficiently.

Suda also holds farmland, and he grew vegetables throughout all four seasons, sending a portion of his crops to market. After the nuclear plant disaster, however, his crops started fetching only about a tenth of their former prices, no longer even covering the cost of growing and harvesting them. He threw out his onions and gave up on planting rice, cucumbers and eggplant.

"There's no point in growing contaminated crops," he said. "A supplemental income of around 400,000 yen a year gone, just like that."

Another blow to Suda was Takahiro's difficult decision to leave the prefecture. Takahiro is a senior at high school, where a teacher had expressed confidence that Takahiro could find work at one of the prefecture's major corporations.

However, in addition to unfavorable job-seeking conditions caused by the nuclear disaster, the area around his home was contaminated enough that it could be officially recommended for evacuation.

"I'm worried about how much radiation exposure I've had," says Takahiro. "When I'm married and have kids, raising them in Fukushima will be a problem. The Tokyo Electric Power Co. should pay us proper compensation for destroying our lives."

The city government is aiming for a reduction of atmospheric radiation levels in the district to below one microsievert per hour within the next two years, and it will conduct decontamination work on all 367 homes in the Onami district by the end of this year. Sixty-two homes that have 2.5 microsieverts per hour or more of radiation (two microsieverts per hour or more if there are pregnant women or people under 19 in the house) have been identified for emergency decontamination work, all of which is to be handled by private businesses. Decontamination of the remaining 305 homes and surroundings like roads used by children going to school will be divided between businesses and residents.

The highest radiation at Suda's home was near a rain gutter, at 34 microsieverts per hour. When private sector workers hired by the city came to get measurements on Oct. 17, a measuring device that the city had prepared couldn't measure high enough, and one of the private sector workers' measuring devices had to be used.

On Oct. 18, private sector workers wearing rain jackets, helmets and goggles used a pressure washer to clean from high places to low, starting with the roof and rain gutters. Garden trees that Suda's 88-year-

old mother Satai had tended for half a century were all removed. There was still worry about how much the radiation levels would actually fall after the work was all done.

Takahiro is scheduled to attend a university in Tokyo in spring of 2012. Suda says, "I'd like for him to take on this home, but considering the health risks, I can't force him."

He added, "Even if the radiation levels fall, our old lives will not come back," and with leaden eyes, watched the decontamination work.

(Mainichi Japan) October 18, 2011

PM hints at approval for some nuclear reactors under construction

Prime Minister Yoshihiko Noda has suggested that he will give the green light to operations of some nuclear reactors under construction.

"The construction of some nuclear power plants has progressed to a great extent. I'll make a final decision on each of them while considering the opinions of the local communities," Noda said in an interview with the Mainichi Shimbun and other media organizations at his office on Oct. 17.

He apparently made the remarks while keeping in mind the No. 3 reactor at the Shimane Nuclear Power Plant, 90 percent of whose construction work has been finished.

Noda had told a news conference when he took office that it would be difficult to install new nuclear reactors.

The prime minister for the first time pointed to the possibility that a housing complex for government workers, which had been under construction in the Saitama Prefecture city of Asaka, will be cancelled altogether. "We'll leave a final decision, including whether to scrap the project, to the discretion of a Finance Ministry study panel deliberating on it."

The government has decided to freeze the construction of the apartment complex for the next five years.

Prime Minister Noda also emphasized that Japan will benefit from participating in the Trans-Pacific Partnership (TPP) agreement. "The Asia-Pacific region will definitely be the driving force behind economic growth from now on. Pursuing a close economic alliance will bring benefits to Japan."

He said he will decide on the timing of joining in TPP negotiations at an early date.

However, he pointed to the need to clearly explain Japan's plan to participate in the TPP accord to agricultural bodies, medical associations and other skeptical industries. "There are some industrial sectors that are worried about it."

Noda stopped short of clarifying the timing of making a decision on the sticky issue of relocating the U.S. Marine Corps Air Station Futenma in Okinawa Prefecture while maintaining that he respects the

bilateral agreement to relocate it to the Henoko district of Nago, Okinawa Prefecture. "I can't say when, but will draw a conclusion as early as possible."

The prime minister said he cannot comply with the largest opposition Liberal Democratic Party's demand that the period of redemption of special bonds that the government will issue to cover disaster recovery efforts be largely extended.

"If we agreed to extend it to 60 years, it'd be equal to construction bonds. It's impossible to comply," he said, adding that he will consider how far the government can compromise with the opposition request.

He also reiterated that he cannot accept any unofficial interviews with the media while walking around the Prime Minister's Office.

"My basic position is I don't comply. However, it's important to provide an explanation to the public through news conferences and official interviews, which I'd like to do," he said.

Year-end 'cold shutdown' target for Fukushima plant cited in road map

In this June 30, 2011 photo released on July 5, 2011, by Tokyo Electric Power Co., sliding concrete slabs, seen above orange floats, have been set in the upper part of a sluice screen for the Unit 2 reactor at the tsunami-crippled Fukushima No. 1 Nuclear Power Plant in Okuma, Fukushima Prefecture, as part of TEPCO's efforts to reduce the leaking of radiation contaminated water into the ocean. (AP Photo/Tokyo Electric Power Co.)

TOKYO (Kyodo) -- The government and Tokyo Electric Power Co. stipulated on Monday in the latest work schedule to contain the nuclear crisis at the Fukushima Daiichi power plant that they will seek to achieve a stable condition called "cold shutdown" by the end of this year, as earlier stated by government officials.

Adding to signs that restoration efforts are proceeding steadily, they also said in the road map, which is updated every month, that they have reduced the massive amount of highly radioactive water

accumulating at the plant and that the amounts of radioactive substances leaking from the crippled reactors have further declined.

Realizing a cold shutdown and reducing the amount of contaminated water are part of the key goals of the so-called "step 2" phase of the road map, and the government and the plant operator known as TEPCO had initially aimed to end the step by January at the latest.

The government has defined that a cold shutdown condition means that the bottom part of a reactor's pressure vessel at the plant is kept below about 100 C, and that radiation exposure caused by the release of radioactive substances is being "significantly" held down.

The temperature of the pressure vessels of all of the crippled Nos. 1 to 3 reactors was between 73 C and 83 C as of Saturday, while radioactive substances currently leaking from the reactors have further declined to a maximum 100 million becquerels per hour, or about one eight-millionth of the level seen in the early days of the crisis in March.

The estimate is half the amount announced a month earlier and means that a person could be exposed to up to 0.2 millisievert when standing around the plant for one year, below the government-set target limit of 1 millisievert per year.

But an official of the government's nuclear regulatory body said it needs more assessment on the radioactive emissions from the No. 3 reactor and has to check whether the plant's safety can be ensured in the medium-term before declaring the end of the step 2 phase.

Nuclear disaster minister Goshi Hosono told reporters in Fukushima Prefecture that it would be difficult to scale back the 20-kilometer no-go zone around the plant immediately after the step 2 stage is completed, because there is still work to do, such as land decontamination.

Hit by a magnitude-9.0 earthquake and tsunami on March 11, the Fukushima nuclear plant lost nearly all its power sources and consequently the ability to cool the reactors and spent fuel pools at the Nos. 1 to 4 units. The buildup of heat and gas inside has led to a series of explosions, and the Nos. 1 to 3 reactors have been badly damaged.

As injection of water to cool the reactors creates radiation-polluted water, TEPCO has created a system that removes radioactive substances from the water and recycles the water to be used as a coolant.

TEPCO said contaminated water accumulating at the reactor turbine buildings have declined to around the target level so that it would not overflow even in cases of heavy rain or when the operation of the water processing facility is suspended for a lengthy period.

The utility separately announced an estimate that, among the Nos. 1 to 3 reactors, the probability of another reactor core being further damaged would be once in 5,000 years, compared with once in 1 million to 10 million years in the case of normal reactors.

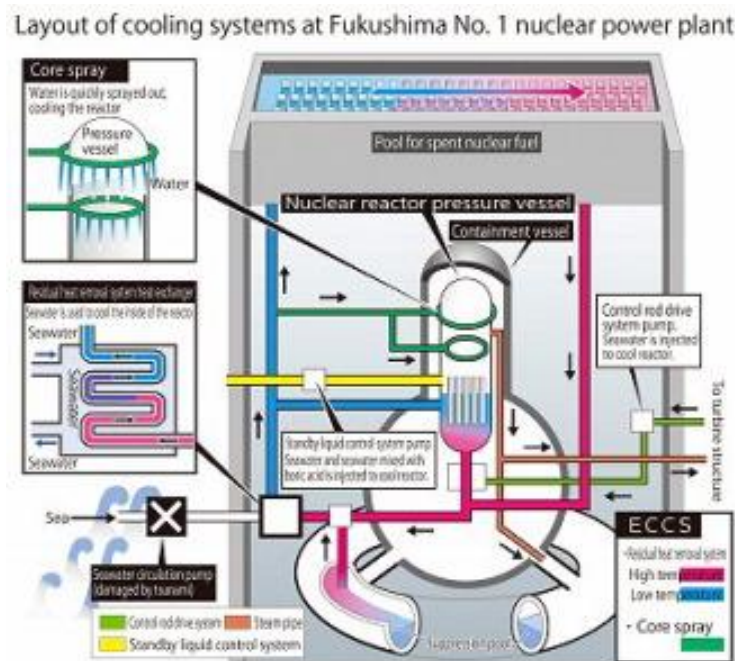

Among factors that may lead to a rise in the temperature of a reactor core to above 1,200 C, and thus damaging the core, the utility said that massive tsunami waves and loss of water injection functions have far higher possibilities of resulting in such a phenomenon than others.

A TEPCO official said the probability is large because numerous makeshift facilities currently exist at the plant, explaining that the figure does not suggest increasing danger.

"We will consider taking further measures in areas that have been found to be weak points," the official said.

(Mainichi Japan) October 18, 2011

Criteria for 'cold shutdown' of Fukushima nuclear plant remain vague and ambiguous

Layout of cooling systems at the Fukushima No. 1 Nuclear Power Plant. (Mainichi)

The government and Tokyo Electric Power Co. (TEPCO) unveiled a revised roadmap to contain the crippled nuclear reactors at the Fukushima No. 1 Nuclear Power Plant on Oct. 17, clearly stipulating that they would aim for a stable condition called a "cold shutdown" of the reactors by the end of this year, but the criteria used to thrash out the work schedule are vague and ambiguous.

It is still not clear whether they can judge that they have achieved a cold shutdown only by checking the temperatures of the bottoms of reactor pressure vessels. On the assessment of the amounts of radioactive substances being released from the nuclear reactors, the government and TEPCO, the operator of the troubled Fukushima nuclear complex, must come up with more detailed data than "provisional figures" in order to say definitely that they have "achieved" a cold shutdown. Furthermore, the government and TEPCO failed to show any direction on the timing of lifting of evacuation

advisories -- the final goal of the nuclear disaster response roadmap, let alone prospects for measures that should be taken after a cold shutdown is achieved.

According to the government's statements to the Diet, the definition of a cold shutdown of the Fukushima nuclear plant consists of 1) the temperatures of the bottoms of the reactor pressure vessels being held down below 100 degrees Celsius, 2) radioactive substances from the reactors being managed and controlled, and 3) stable maintenance of "circular cooling systems" designed to recycle radioactive water from the reactors as coolant.

The temperatures of the bottoms of the No. 1, 2 and 3 reactors, which suffered core meltdowns, have stayed below 100 degrees Celsius since Oct. 1, and these conditions served as the reason to decide to bring forward the target deadline to achieve a cold shutdown. **But melted fuels are believed to have dropped to the floors of containment vessels from the pressure vessels, and therefore it is difficult to assess the conditions inside reactor cores by measuring the temperatures of the bottoms of the pressure vessels alone.**

According to the work schedule to stabilize the nuclear reactors released by TEPCO on Oct. 17, the temperature of the melted fuel that was dropped to the containment vessels is estimated to be about 150 degrees Celsius.

TEPCO official Junichi Matsumoto said, "There is no problem because the melted fuel is sufficiently cooled down by water injection from above." But Hiroshi Yamagata, an official of the government's Nuclear and Industrial Safety Agency (NISA), only said, "We will discuss its validity from now on."

According to the revised roadmap, the amounts of radioactive substances being released from the nuclear reactors are 40 million becquerels per hour at the No. 1 reactor, 10 million becquerels per hour at the No. 2 reactor, and 40 million becquerels per hour at the No. 3 reactor. The combined total amount of radioactive substances being released from the reactors stands at about 100 million becquerels per hour, about one eight-millionth of what was measured on March 15, four days after the outbreak of the nuclear crisis.

But on the amount of radioactive substances being released from the No. 3 reactor, which has yet to be fully measured, NISA said, "It is nothing but a provisional figure." They plan to measure the amount of radioactive substances again by the end of this year and see if the annual dose of radiation at the outer premises of the nuclear plant is held down below the legally acceptable level of less than one millisievert per year.

On the lifting of evacuation advisories, Cabinet Office Parliamentary Secretary Yasuhiro Sonoda said, "Depending on progress in the work schedule, I believe it will be discussed little by little." But he stopped short of giving a specific timeframe for such discussions.

(Mainichi Japan) October 18, 2011

High levels of radiation detected near elementary school pool in Tokyo

High levels of radiation were detected near a pool at an elementary school in Tokyo, prompting officials to cordon off the area.

The Adachi Ward Office announced on Oct. 17 that 3.99 microsieverts of radiation per hour were detected near a machine house for a pool at the Higashifuchie Elementary School in the ward.

According to the ward office, the high levels of radiation were observed five centimeters above the ground below a gutter attached to the machine house. Since there is no drainage, it is easy for water to accumulate in the area, ward officials said. Officials have taken such emergency measures as roping off the area to prevent people from entering.

"We believe the levels detected are localized and would not affect human health, but we will look into our response as soon as possible," said a ward official in charge of crisis management.

The radiation scare emerged after local residents voluntarily measured radiation and detected 1 microsievert or more per hour of radiation at five locations in the ward including the elementary school. The residents' move prompted the ward to conduct its own measurement, which has detected levels of radiation ranging from 0.43 to 0.95 microsieverts per hour at the four remaining locations including a park.

Adachi Ward has set its own safety limit, at 0.25 microsieverts per hour, and is supposed to decontaminate an area if higher levels of radiation than the limit are detected. The radiation levels detected in the five locations all exceeded the ward's safety standards.

(Mainichi Japan) October 18, 2011

High radiation detected at Tokyo school

The Yomiuri Shimbun - <http://www.yomiuri.co.jp/dy/national/T111018004800.htm>

Radiation of nearly 4 microsieverts per hour--a level that slightly exceeds the government-set benchmark for designating evacuation zones--was detected Monday at a primary school in Adachi Ward, Tokyo, ward officials said.

The reading was recorded under the drainpipe attached to a gutter of a machinery room next to a swimming pool at Higashi-Fuchie Primary School. Tests conducted Monday found radiation of 3.99 microsieverts per hour at five centimeters above the ground. At the same point, 0.41 microsieverts per hour was measured at a height of 50 centimeters, and 0.24 microsieverts per hour at one meter.

Ward officials have made the area around the "hot spot" off-limits to students. The area will be decontaminated and the topsoil removed, the officials said.

A radiation reading of 3.99 microsieverts per hour equates to a cumulative dose of about 21 millisieverts a year, surpassing the 20-millisieverts-a-year standard the government used to designate expanded evacuation zones after the crisis erupted at the Fukushima No. 1 nuclear power plant, according to the officials.

"The high reading possibly was caused by the accumulation of rainwater that contained radioactive material released at the outbreak of the nuclear accident," a ward official said.

The ward office measured radiation levels at the school Monday after being tipped off by residents who had detected high readings at 20 locations in the ward. The office chose five of the 20 points--including Higashi-Fuchie Primary School--where residents had found radiation levels of more than 1 microsievert per hour.

(Oct. 19, 2011)

Tokyo ward decontaminates areas near elementary school

Workers bury bags containing contaminated soil and measure their depth near Higashifuchie Elementary School in Adachi Ward, Tokyo, on Oct. 18. (Mainichi)

Officials from Tokyo's Adachi Ward, where high radiation levels were detected near an elementary school, announced Oct. 18 that radiation levels decreased significantly after they took immediate measures to decontaminate the affected areas.

The Adachi Ward Office on Oct. 18 removed about 10 centimeters of tainted topsoil found below the gutter of a pool machinery room at the Higashifuchie Elementary School in the ward on Oct. 17.

Ward officials announced that after carrying out the soil decontamination, radiation levels decreased to 0.15 microsieverts per hour from the 3.99 microsieverts initially detected at the school.

The removed soil was placed in bags and buried in the ground approximately 4.5 meters away from the elementary school.
